and was borne by those who succeeded him on the imperial throne of the Holy Roman Empire. Although this dignity came to an end with the resignation of Francis II. in 1806, the title Kaiser is still assumed by the emperor of Austria. (Bryce, *Holy Roman Empire*.)

Cæsarean Operation. The extraction of the child from the womb by an operation. Julius Cæsar is said to have been thus brought into the world.

Cæsium. An alkaline metal discovered by Bunsen and Kirchhoff in 1860, by a spectral analysis of the residue of the mineral water of Durckheim and Baden. A ton of the water was estimated to yield not more than three grains of chloride of cæsium. The metal derives its name from the Latin *cæsius*, signifying greyish blue, this being the colour of the two lines produced in its spectrum. Traces of it have been found in other waters. It is a white metal; it decomposes water, evolving hydrogen, and forming an alkaline solution of protoxide of cæsium.

Cæstus. [ATHLETES.]

Cæsura (Lat. from *cædo*, *I cut*). In Prosody, a metrical break in the verse, occasioned by the separation of the first syllable of a foot, forming the last of a word, from the next syllable, forming the first of another. In the Latin hexameter the principal cæsura, without which the line is unmusical, occurs generally after the tenth, sometimes not until after the fourteenth time—each long syllable containing two times, each short syllable one [RHYTHM]—thus:

Arma virumque cano | Trojæ qui primus ab oris.
Speluncæ vivique lacus | at frigida Tempe.

The slight pause which follows the syllable at which the interruption takes place is termed the cæsural pause. In English verse a line is frequently musical without any cæsura at all; i.e. in which the pause takes place always at the end of a foot. But a cæsura in the middle of the third and in the middle of the fourth foot of an heroic verse are by no means uncommon, and particularly appropriate in blank verse, in which they represent the two common cæsures of the Latin hexameter.

I sing the sofa | I who lately sang.
Of man's first disobedience | and the fruit.

In the first of these lines the cæsura is in the third, in the latter in the fourth foot.

Caffèic Acid. *Caffotannic* or *chlorogenio acid*. An astringent substance existing in coffee. It much resembles gallotannic acid.

Caffein. A bitter crystallisable substance contained in coffee. A portion of it volatilises during the roasting of coffee. It has not been applied to any use. [TEA.]

Cahier (Fr.). Derived by some from the Lat. *codex*, by others from *quaternio*. It signifies in its proper sense a number of sheets of paper loosely tied together. In French history, it denotes the reports and proceedings of certain assemblies: as those of the clergy, the States-General, the notables, &c. The

CAIMACAN

famous cahiers presented by the States-General to the king of France at their convocation on the 24th of June, 1789, contains the best account of the then state of France. They were systematised and condensed in a book in three volumes, called *L'Esprit des Cahiers*.

Caimacan. [*KAIMACAN*.]

Cahoun-nuts. The fruits of *Attalea funifera*, which yield an oil resembling that of the cocoa-nut.

Caincio Acid. A peculiar acid discovered by Pelletier and Caventou in the bark of the cainca root, a Brazilian shrub employed for the cure of intermittent fever.

Cainites. A strange sect of heretics, who appeared about 159 A.D. They probably originated in some of the various schools of Manicheism; and, if their doctrines are truly reported to us, they are said to have asserted that the power which created heaven and earth was the evil principle; that Cain, Esau, Korah, the people of Sodom, and others whom the Old Testament represents as victims of peculiar divine judgments, were in fact children of the good principle, and enemies of the evil. Some of them are said to have published a gospel of Judas on the same principle. The Quintilianists, so called from a lady named Quintilia, of whom Tertullian speaks, were an offshoot of this sect.

Cairn. A Celtic word, used to denote the piles of stones of a conical form frequently found on the tops of hills &c. in various districts; erected probably, as Sir R. C. Hoare observes, in general, for the mere purpose of memorials, although some have assigned to them a peculiar character, as receptacles for the bodies of criminals burnt in the wicker images of the Druids, &c. According to some antiquaries, *cairn* is distinct from *carnead*, the Welsh name for heaps of stones on the tops of high mountains (*Carnead* David, *Carnead* Llewellyn, &c.), which are said to have been sacrificial. Some cairns are undoubtedly sepulchral. In common language, a *cairn* is distinguished from a barrow, the former being a heap of stones, the latter a mound of earth; but in all probability they had for the most part the same object, and the difference of materials was merely occasioned by local circumstances. [*BARROW*.]

Cairngorm or Cairngorum Stone. The name given to pellucid wine-yellow varieties of Smoky Quartz, after the mountain Cairngorm in Inverness-shire, where they are found. They are also common in Scotland, throughout the central group of the Grampian Hills.

Caisson (Fr.). In Architecture, a sunken panel, in a flat or vaulted ceiling, or in the soffit of a cornice; in ceilings they are of various geometrical forms, and often are enriched with rosettes or other ornaments. In Civil Engineering, a *caisson* means an enclosure or large vessel, in which the foundations of a bridge are built in the dry; and the vessel being brought over the position assigned to it (the ground being first properly dredged, or prepared to receive it), the sides are removed,

CALADIUM

and the whole structure then subsides into its place. Sometimes the sides are designed to remain; and the foundations in those cases are protected by loose stones thrown down around the caisson. Westminster and Blackfriars bridges and Ramsgate pier were founded in this manner, which was a favourite one with the engineers of the last century; but it has not been found sufficient to protect the superstructure from the scour of the tides or currents. The term *caisson* is also applied to a kind of gate for the purpose of closing the entrance to graving docks or other similar works.

Cajanus (Catjang, the Malay name of one of the species). A small genus of *Leguminosae* § *Papilionaceae*, one species of which, *C. indicus*, is cultivated in tropical countries for the sake of its pulse, which is much used as food, under the names of Dhal, Congo Pea and Pigeon Pea. They are shrubby plants with trifoliate leaves, and axillary racemes of flowers, which are either yellow, or yellow streaked outside with crimson. The seeds, whether green or dry and split, are considered equal to peas.

Cajuput Oil. A volatile oil obtained by distilling the leaves of the *Melaleuca minor*, a shrub abundant in Amboyna and Borneo, whence the oil is imported. This oil is of various shades of green, highly pungent and aromatic, and powerfully stimulant and diaphoretic. It has been much extolled as a remedy in the Asiatic cholera, but other essential oils are probably as effectual.

Caking Coal. A term applied to those kinds of bituminous coal which form a pasty cake, or swell and expand in the fire somewhat in the manner of borax when exposed to heat.

Calabar Bean or Ordeal Bean. This is the produce of the *Physostigma venenosum*, and is imported from Africa, where it is used medicinally and as an ordeal in cases of suspected crime: if it causes vomiting, it indicates innocence; if purging, crime. It operates as an emetic and purgative, and also as a narcotic poison: it induces fainting fits and partial paralysis. Several cases are on record of accidental poisoning by this bean. In 1864 several children were poisoned by it at Liverpool, and one of them died; they had picked up the beans in some rubbish thrown upon a piece of waste ground, and derived from part of the cargo of a ship from Calabar. (*Pharm. Journ.* vi. 134.) See also a paper on this subject by Dr. Christison, who was nearly poisoned by eating about a fourth part of one of these beans. (*Phil. Trans. Edinburgh*, 1856.)

Caladium (of unknown derivation). The name of certain Araceous plants, the rhizomes or rootstocks of which are eaten as food in the West Indies and other tropical countries, the process of cooking removing the noxious qualities which, in common with other Arads, they possess from the abundant starch which they contain. The spathe is hood-like, rolled round the spadix, which bears ovules at the base, stamens at top, and blunt glands or sterile stamens between.

CALAMARY

Calamary (*calamus, a pen*; theca *calamaria, the pen-fish*). A Cephalopod; so called because it has a horny substance shaped like a quill in its back, and contains an ink-bag in its visceral sac: it is the *Loligo vulgaris* of Cuvier.

Calamine (Lat. *calamus, a reed*). One of the most abundant ores of zinc, used in the manufacture of brass; *Lapis Calaminarius*. The name has reference to the way in which the ore, during the process of smelting, adheres to the bottom of the furnace in the form of reeds.

It is a native carbonate of zinc, composed of 64.81 per cent. of oxide of zinc and 35.19 carbonic acid, and containing, when pure, 52.02 per cent. of zinc; but it is frequently rendered impure by admixtures of the carbonates of iron and manganese, peroxide of iron, lime, barytes, clay, electric calamine, cadmium, and other substances.

Crystals of this mineral are rare; it is mostly found in kidney-shaped, botryoidal, stalactitic, cellular, and other imitative shapes. The colour is white, yellowish, grey or brown, with a vitreous lustre, and it is opaque or occasionally translucent.

Calamine occurs in veins, beds, and large deposits termed pockets, and also in lodes, in metamorphic limestone, and in the Devonian, Carboniferous and Oolite formations; and is frequently (as at Altenberg) associated with silicate of zinc (Smithsonite) and Bitter Spar. Large quantities were formerly raised in Northumberland, Cumberland, Derbyshire, and Somersetshire. In the Mendip Hills of the latter county, the ore lies in the Magnesian Conglomerate, and was worked at Shipham, Roborough, near Rickford, and on Broadfield Down. In Derbyshire it is found in carboniferous limestone near Castleton, Wirksworth, and Matlock; in Ireland, in Donegal and Galway, and very largely (in an earthy form) at Silvermines in the county of Tipperary, between the carboniferous limestone and dolomite.

Considerable quantities of Calamine are brought to this country from Spain, where enormous deposits occur for many miles along the north-west coast from Santander into the Asturias, and in Biscay; and from Altenberg or the Vieille Montagne mines, situated in the neutral parish of Moresnet, between Belgium and Prussia. The other chief foreign localities are Tarnowitz and the district of Beuthen in Upper Silesia; Westphalia, at Brilon, and in the neighbourhood of Stolberg in the districts of Aachen and Eupen; Bleiberg and Raibell in Carinthia; Hungary; Siberia; Jefferson county, Missouri; Mexico; China, &c. [HARRINGTON.]

According to Dr. Wedding, throughout the States forming the German Commercial Union or Zollverein, Calamine and Blende occur in exactly the same series of geological groups as lead-ores, except that they are absent from the Bunter formation, and are most plentiful in Eifel limestone and the Muschelkalk beds. Calamine is a result of the decomposition of other ores of zinc; in the Black Forest many lead-ores contain Calamine in the upper parts and Blende in the lower.

CALCAREOUS SPAR

This ore of zinc is the Smithsonite of Dana, Erdmann, Von Kobell, Haidinger, and some other mineralogists, who, on the other hand, call Smithsonite, or the silicious oxide of zinc, Calamine: a striking instance of the confusion which is caused in mineralogical nomenclature by want of agreement amongst authors.

Calamite (Lat. *calamus, a reed*). A soft translucent kind of Tremolite of an asparagus-green colour, found in rhombic prisms in Serpentine, at Normarken in Sweden.

Calamus (Lat.). The name of a genus of Palms which yields the Canes or Battans of commerce. These are the produce of *C. Rotang, rudentum, viminalis*, and others, and are used in this country for the bottoms of chairs and couches, the sides of carriages, &c., while in their native countries they are employed in making baskets, mats, hats, and other useful articles. They are also used as ropes or cables in the junks and coasting vessels, and take the place of chains in native suspension bridges. Their thin reed-like stems grow up to a great height amongst other trees, and bear pinnate leaves and long branching flower-spikes. *C. Scipionum* furnishes the walking-sticks known as Malacca canes.

Calamus Aromaticus (Lat.). The rhizome of the *Acorus Calamus*, common over the whole of Europe in moist situations: it is usually known under the name of Sweet Flag. An infusion of the root is a good aromatic tonic. It yields a very small portion of essential oil when distilled with water (scarcely exceeding a thousandth part of its weight), which is used by perfumers.

Calathium or **Calathidium** (Gr. *καλῶθιον, a little basket*). A botanical term, employed by some German botanists to denote that kind of depressed contracted inflorescence which is found in composite flowers. It is in reality an umbel with all the flowers sessile.

Calatrava, Order of (in Spain; so denominated from a castle taken from the Moors). Was instituted by Sancho III., king of Castile, in 1158. The kings of Spain are perpetual grand masters of this order of knighthood.

Calc Grit. The name given to a subordinate member of the Oolitic series of rocks in England, lying above and below the coral rag. This rock consists of crushed shells mixed with a large proportion of sand, the whole cemented into a poor gritstone with laminae of clay, and passing into tough marly rock. [CORAL RAG.]

Calcanthum. Pliny's term for Copperas, or sulphate of iron.

Calcar (Lat. *a spur*). This term is applied by botanists to all hollow prolongations downwards or backwards of leaves or the parts of a flower. The long hollow horns which hang down from one of the sepals of a *Tropaeolum*, or from the lip of an *Orchis*, or the curved bodies enclosed within the hood of an Aconite flower, are described by this name.

Calcareous Spar. Crystalline carbonate of lime, composed (when pure) of 44 per cent. of carbonic acid and 56 lime.

CALCAREOUS TUFA

It occurs massive, disseminated and crystallised, in numerous forms, all of which are reducible to an obtuse rhombohedron, which is the primary form. The colour is generally white, with a vitreous lustre, but sometimes it is of various shades of grey, red, green, or yellow, owing to an admixture of iron, manganese, bitumen, or other impurities. It passes from perfect transparency to complete opacity. The white transparent varieties are often iridescent.

The purest and most limpid kind of calcareous spar is that procured in Iceland [ICELAND SPAR], which, in common with other transparent varieties, exhibits double refraction to a remarkable degree.

Calcareous spar is a mineral of universal occurrence, found in veins and rocks belonging to every formation, in all parts of the world.

Calcareous Tufa or Calc Tuff. A variety of carbonate of lime deposited on and about the margins of waters containing carbonate of lime in solution, in consequence of the evaporation of the water and the escape of carbonic acid. The softer, looser, and more friable kind is generally called *Calcareous Tufa*; the harder and more coherent sort, *Travertine*. The latter (the *Lapis Tiburtinus*, or *Tiber Stone*, of the ancients) is so called because large masses of it abound on the banks of the river of that name. The Coliseum at Rome and the temples of Paestum are built of this stone. The incrustations of carbonate of lime formed on plants and other objects, by what are called petrifying springs, are deposits of this nature; examples of which are afforded by the springs at Matlock, by those of the cascade of Tivoli in Italy and of many other localities where the same action is going on. Remarkable deposits of this kind are stated by Bischof to occur at Königsutter, near Brunswick, and in the Trieb valley, near Meissen. The calcareous tufa which was deposited in the Roman aqueducts, extending from the heights of the Eifel to Cologne and Trier, is also stated by the same authority to occur in such large masses that columns made from it are found here and there in the churches of the Eifel. Some of the limestones at the lower part of the Purbeck formation have been deposited in the form of tufa; and a mass of calcareous tufa of some extent and thickness has been formed at Blashenwall in Dorsetshire from springs which contain carbonate of lime dissolved out of the Purbeck limestones, and which are still flowing.

Chalcedony. A variety of Agate in which opaque white Chalcedony or Caccholong alternates with translucent greyish Chalcedony.

Calceolaria (Lat. *calceolus*, a small slipper). A genus of beautiful herbaceous or shrubby plants with yellow, or orange, or purple flowers, the lower half of which is shaped something like an old-fashioned slipper. They naturally inhabit rocks, rich plains, and woods, in Chili, Peru and New Grenada. In this country many of them are hardy enough to live in the open

CALCULUS

air in summer; and some will even endure our winters, if not very severe. They are, however, all cultivated with most success if regarded as greenhouse plants.

Calciferite (Lat. *calx*, lime, and *ferrum*, iron). A hydrated phosphate of iron and lime related to Vivianite; found in the form of yellowish nodules in a deposit of clay at Battenberg, in Rhenish Bavaria.

Calcigrade (Lat. *calx*, the heel; *gradier* I walk). When an animal's heel in walking sinks deeper than the rest of its foot.

Calcination. The reduction of substances to cinder or ash. The term is derived from the Latin word *calx*; quicklime, which, as is well known, is prepared by the action of heat upon limestone; and hence the old chemists employed the word *calcination* to express any supposed analogous change, metallic substances being apparently converted into earthy matter by calcination.

Calotte (Lat. *calx*, lime). A general term under which are comprised the different varieties of carbonate of lime.

Calcium. The metallic base of lime, discovered in 1808 by Davy. This substance has hitherto been obtained in such small quantities, that its properties have not been accurately investigated. It is probably a yellowish, hard, and ductile metal, highly inflammable, and nearly twice as heavy as water. Combined with oxygen it forms lime, which consists of 20 calcium + 8 oxygen = 28 lime.

Calculating Machine. A piece of mechanism for assisting the human intellect in the performance of arithmetical operations. Amongst the various machines which have been invented for this object, the two devised by Mr. Babbage, but never fully executed, are by far the most elaborate. Descriptions of these, and much general information on the subject, will be found in Mr. Babbage's *Pasages from the Life of a Philosopher*, London 1864, and in his forthcoming *History of the Analytical Engine*.

Calculation, Calculus (Lat. *calculus*, a small pebble, the Romans having made use of pebbles in casting up accounts). In modern language, the term *calculus* is employed to denote any branch or any operation of mathematics which requires or may involve numerical calculation; and therefore may be applied to the whole of the mathematical sciences, excepting pure geometry. Thus that part of algebra which treats of exponents is called the *exponential calculus*. In like manner the phrases *calculus of definite integrals*, *calculus of functions*, *calculus of variations*, &c., are used to denote certain branches of the higher mathematics. [DIFFERENTIAL CALCULUS; INTEGRAL CALCULUS; VARIATIONS.]

Calculus (Lat.). In Physiology, the general term for inorganic concretions of various kinds, formed in various parts of the body, and bearing in shape or composition a general resemblance to stones. The term *calculus* is, however, generally confined to urinary concretions.

Caldarium (Lat.). In ancient Architecture, by some authors used in the sense of Laconicum; it was an apartment in a bath heated for the purpose of causing perspiration. Vitruvius, however, uses the word to signify a hot bath.

Caldarite. A massive variety of Garnet found in Nepal.

Caledonite. A cupreous sulpho-carbonate of lead, found in minute bluish green crystals, associated with other ores of lead, at Leadhills in Lanarkshire and at Roughten Gill in Cumberland. It is, also, said to occur in the Harz, and at Mine la Motte in Missouri.

The word Caledonite, derived from *Caledonia*, has reference to the locality where the mineral was originally discovered.

Calembour. A French expression for what in English is called a pun. A certain Westphalian Count Calemburg (Kahlenberg), who visited Paris in the reign of Louis XV., and was famous for his blunders in the French language, is said to have given the name to this species of jeu de mots.

Calendar (Lat. *calendarium*). A distribution or division of time into periods adapted to the purposes of civil life; also a table or register of such divisions, exhibiting the order in which the seasons, months, festivals, and holidays succeed each other during the year. The word is derived from the ancient Latin verb *calare*, to call. In the early ages of Rome, it was the custom for the pontiffs to call the people together on the first day of each month, to apprise them of the days that were to be kept sacred in the course of it. Hence *dies calende*, the calends or first days of the different months.

The calendars in use throughout Europe are borrowed from that of the Romans. Romulus is supposed to have first undertaken to divide the year in such a manner that certain epochs should return periodically after a revolution of the sun; but the knowledge of astronomy was not then sufficiently advanced to allow this to be done with much precision. According to the legend, he placed the commencement of the year in spring, and divided it into ten months—March, April, May, June, Quintilis, Sextilis, September, October, November, and December. March, May, Quintilis, and October contained thirty-one days each; the other six contained only thirty. The names Quintilis and Sextilis remained in the calendar till the end of the republic, when they were changed into July and August; the former in flattery of Julius Cæsar, and the latter of Augustus.

According to the mythical history, the year of Romulus contained only 304 days. Numa, it is said, added two months; January to the beginning of the year, and February to the end. About the year 462 a.c. this arrangement was changed by the Decemvirs, who placed February after January; since that time the order of the months has remained undisturbed. In Numa's year the months consisted of 29 and 30 days alternately, to correspond with the synodic revolution of the moon. The year would there-

fore consist of 364 days; but one day was added to make the number odd, as being more lucky. In order to produce correspondence with the solar year, Numa ordered an intercalary month to be inserted every second year between the 23rd and 24th of February, consisting alternately of 22 and 23 days. Had this regulation been strictly adhered to, the mean length of the year would have been 366½ days, and the months would have continued for a long time to correspond with the same seasons. But a discretionary power over the intercalary month was exercised by the pontiffs, who frequently abused it for the purpose of hastening or retarding the days of the election of magistrates: and the Roman calendar continued in a state of uncertainty and confusion till the time of Julius Cæsar, when the civil equinox differed from the astronomical by three months. (For a critical examination of the traditions relating to the early Roman calendar, the reader is referred to Sir G. C. Lewis's *Astronomy of the Ancients*, ch. i.)

Under the advice of the astronomer Sosigenes, Cæsar abolished the lunar year, and regulated the civil year entirely by the sun. He decreed that the common year should consist of 365 days; but that every fourth year should contain 366. In distributing the days among the different months, he ordered that the odd months, that is, the first, third, fifth, seventh, ninth and eleventh, should contain each 31 days, and the other months 30, excepting February, which in common years was to contain only 29 days, but every fourth year 30 days. This natural and convenient arrangement was interrupted to gratify the frivolous vanity of Augustus, by giving August, the month named after him, an equal number of days with July, which was named after the first Cæsar. The intercalary day, which occurred every fourth year, was inserted between the 24th and 26th of February. According to the peculiar and awkward manner of reckoning adopted by the Romans, the 24th of February was called the sixth before the calends of March, *sexto calendas*. In the intercalary year this day was repeated, and called *bis-sexto calendas*; whence the term *bissextile*. The corresponding English term, *leap year*, appears less correct, as it seems to imply that a day was *leapt* over instead of being thrust in. It may be remarked, that in the ecclesiastical calendar the intercalary day is still inserted between the 24th and 26th of February.

The Julian year consisted of 365½ days, and consequently differed in excess by 11 minutes 10·85 sec. from the true solar year, which consists of 365 d. 5 h. 48 m. 49·62 sec. In consequence of this difference the astronomical equinox, in the course of a few centuries, fell back sensibly towards the beginning of the year. In the time of Julius Cæsar it corresponded to the 26th of March; in the sixteenth century it had retrograded to the 11th. The correction of this error was one of the

CALENDAR

purposes sought to be obtained by the reformation of the calendar effected by Pope Gregory XIII. in 1582. By suppressing 10 days in the calendar, Gregory restored the equinox to the 21st of March, the day on which it fell at the time of the council of Nice in 325; the place of Easter and the other movable church feasts in the ecclesiastical calendar having been prescribed at that council. And in order that the same inconvenience might be prevented in future, he ordered the intercalation which took place every fourth year to be omitted in years ending centuries; that is to say, on the 100th, 200th, &c.; excepting on the 400th and the years which are multiples of 400. The Gregorian rule of intercalation may therefore be expressed as follows:—

'Every year of which the number is divisible by 4 without a remainder is a leap year, excepting the centesimal years, which are only leap years when divisible by 4 after suppressing the two zeros.' Thus 1600 was a leap year; 1700 and 1800 were common years; 1900 will be a common year, 2000 a leap year, and so on.

The Gregorian method of intercalation thus gives 97 intercalations in 400 years; consequently 400 years contain $400 \times 365 + 97 = 146097$ days, and therefore the length of one year is 365.2425 days, or $365 \text{ d. } 5 \text{ h. } 49 \text{ m. } 12 \text{ sec.}$, which exceeds the true solar year by 22.38 sec. , an error which amounts only to one day in 3,866 years.

If an astronomer were required, without any reference to established usages, to give a rule of intercalation by which the commencement of the civil year; while it always coincided with the commencement of a day, should deviate the least possible from the same instant of the solar year, he would proceed as follows: The length of the mean solar year being 365.242241 days, the excess above a whole number of days is .242241, which converted into a continued fraction becomes :

$$\frac{1}{4+1} \frac{1}{7+1} \frac{1}{1+1} \frac{1}{4+1} \frac{1}{7+1} \frac{1}{1+1} \text{ \&c.}$$

Whence the following series of approximate fractions is derived :

$$\frac{1}{4}, \frac{7}{29}, \frac{8}{33}, \frac{39}{161}, \frac{281}{1160}, \frac{320}{1321}, \&c.$$

Of these the first gives an intercalation of 1 day in 4 years, which supposes the year to be 365 $\frac{1}{4}$ days. The second gives 7 intercalations in 29 years, and supposes the length of the year to be 365 d. 5 h. 47 m. 35 sec., which is somewhat too small. The third fraction, $\frac{8}{33}$, is remarkable, as giving a year which differs in excess from the true solar by 16.38 seconds; so that by intercalating 8 times in 33 years, or 7 times successively at the end of every fourth year, and once at the end of the

fifth year, the difference between the civil and solar year would only accumulate to a day in about 5,600 years, while in the Gregorian calendar the error amounts to a day in 3,860 years. Nevertheless the Gregorian rule has this advantage, that leap year is always readily distinguished.

The Gregorian calendar was received immediately or shortly after its promulgation by all the Roman Catholic countries of Europe. The Protestant states of Germany, and the kingdom of Denmark, adhered to the Julian calendar till 1700; and in England the alteration was successfully opposed by popular prejudices till 1752. In that year the Julian calendar, or *old style*, as it was called, was formally abolished by Act of Parliament, and the date used in all public transactions rendered coincident with that followed in other European countries, by enacting that the day following the 2nd of September of the year 1752 should be called the 14th of that month. When the alteration was made by Gregory it was only necessary to drop 10 days; the year 1700 having intervened, which was a common year in the Gregorian but a leap year in the Julian calendar, it was now necessary to drop 11 days. The old style is still adhered to in Russia and the countries following the communion of the Greek church; the difference of date in the present century amounts to twelve days.

Eccelesiastical Calendar.—The adaptation of the civil to the solar year is attended with no difficulty; but the church calendar for regulating the movable feasts imposes conditions less easily satisfied. The early Christians borrowed a portion of their ritual from the Jews. The Jewish year was luni-solar: that is to say, depended on the moon as well as on the sun. Easter, the principal Christian festival, in imitation of the Jewish passover, was celebrated about the time of the full moon. Differences of opinion, and consequently disputations, soon arose as to the proper day on which the celebration should be held. In order to put an end to an unseemly contention, the council of Nice laid down a specific rule, and ordered that Easter should always be celebrated on the Sunday which immediately follows the full moon that happens upon, or next after, the day of the vernal equinox. In order to determine Easter according to this rule for any particular year, it is necessary to reconcile three periods; namely, the week, the lunar month, and the solar year. To find the day of the week on which any given day of the year falls, it is necessary to know on what day of the week the year began. In the Julian calendar this was easily found by means of a short period or cycle of 28 years (*CYCLE*), after which the year begins with the same day of the week. In the Gregorian calendar this order is interrupted by the omission of the intercalation in the last year of the century. But to render any calculation unnecessary, a table is given in the prayer-books, showing the correspondence of the days of the year and the week for the

CALENDER

current century. [DOMINICAL LETTER.] The connection of the lunar month with the solar year is an ancient problem, for the resolution of which the Greeks invented cycles or periods, which remained in use with some modifications till the time of the Gregorian reformation. [METONIC CYCLE; GOLDEN NUMBER.] The author of the Gregorian calendar, Luigi Lilio Ghiraldi, or, as he is frequently called, Aloysius Lilius, employed for the same purpose a set of numbers called Epacts (for an explanation of the use of which, see EPACT). It is to be desired that this complicated system of rules and tables were rendered unnecessary by abolishing the use of the lunar month, and causing Easter to fall invariably on the same Sunday of a calendar month; for example, on the first or second Sunday of April.

New French Calendar.—A new reform of the calendar was attempted to be introduced in France during the period of the Revolution. The commencement of the year was fixed at the autumnal equinox, which nearly coincided with the epoch of the foundation of the republic. The names of the ancient months were abolished, and others substituted having reference to agricultural labours, or the state of nature in the different seasons of the year. But the alteration was found to be inconvenient and impracticable, and after a few years was formally abandoned. [CYCLE; ERA; HÆTRA; YEAR.]

Calender (Fr. *calandre*, Lat. *cylindrus*, Gr. *κύλινδρος*). A machine for pressing and smoothing cloth and other articles, which when so prepared are said to be *calendered*.

Calends (Lat. *calendæ*). In the ancient Roman calendar, were the first days of each month. The Roman month was divided into three periods by the *Calends*, the *Nones*, and the *Ides*. The *Calends* were invariably placed at the beginning of the month; the *Ides* at the middle of the month, on the 13th or 15th; and the *Nones* (*novem*, nine) were the ninth day before the *Ides*, counting inclusively. From these three terms the days were counted backwards, in the following manner: Those days comprised between the *calends* and the *nones* were denominated *days before the nones*; those between the *nones* and the *ides*, *days before the ides*; and those from the *ides* to the end of the month, *days before the calends*. Hence the phrases *pridie calendas*, *tertio calendas*, &c.; meaning the second day before the *calends*, or last day of the month, the third day before the *calends*, or last but one of the month (the *calends* or first day of the following month being included in the reckoning), and so on. In the months of March, May, July, and October, the *ides* fell on the 15th day, and the *nones*, consequently, on the 7th. In all the other months the *ides* fell on the 13th, and the *nones*, consequently, on the 5th. The number of days receiving their denomination from the *calends* depended on the number of days in the month and the day on which the *ides* fell. For example, if the month had

CALIPER COMPASSES

thirty-one days, and the *ides* fell on the 13th (as happened in January, August, and December), there would remain eighteen days after the *ides*, which, added to the first of the following month, made nineteen days of *calends*. Hence the 14th day of January was styled the *nineteenth before the calends* of February; the following day, or 15th of the month, was the *eighteenth before the calends*, and so on.

Calendulina. A mucilaginous substance or species of gum obtained from the marigold.

Calenture (Lat. *calco*). A delirious fever, produced by the sun, in which it is common for the patient to imagine the sea to be green fields.

Calibre (Fr.). The calibre of a gun is the diameter of its bore. It is measured in terms of inches, and in smooth-bored guns is always rather larger than the diameter of the shot.

[WINDAGE.]

Calico Printing. The art of producing figured patterns upon calico; they are transferred to its surface by blocks, copper plates, or engraved cylinders, by which the colours are directly printed, or by which *mordants* are so applied that when the calico is immersed in a colouring bath, the colour adheres or is produced only upon the parts to which the mordant has been previously applied. [DYEING.]

Caliduct (a word coined from the Latin *calor*, heat, and *duco*, I lead). A pipe, or flue, from a source of heat, for the distribution of the same in an apartment or house.

Caligides. A family of parasitic Entomostracous Crustaceans, belonging to the order *Siphonostoma*, characterised by having the mouth organised for piercing and suction. The parasites of this family prey almost exclusively upon fish, and are commonly called fish-lice. Gold-fish are sometimes infested to an almost incredible extent with a species, the *Monoculus foliaceus* of Linnæus, which is nearly a quarter of an inch long, having the body covered with a broad round transparent shield, notched behind to give free motion to the tail. The first pair of legs are shaped like a cupping-glass, for the purpose of holding on;

filaments, probably sub

Caliper Compasses (or simply *Calipers*). Are compasses with curved legs, for measuring the calibre (whence the name) or diameter of cylinders, balls, or other round bodies. Calipers of the best sort are made with a scale having different sets of numbers engraved on it, like a sliding rule, for the purpose of exhibiting at once various relations depending on the magnitude of the diameter of the body measured. Thus, as the weights of balls of the same metal are in a constant ratio to the cubes of their diameters, the scale may be so graduated and numbered that the observer may read off either the diameter in inches or the weight in pounds. Other numbers having a less immediate application are also frequently attached: for example, the degrees of a circle, the proportions of troy

CALIPH

and avoirdupois weight, tables of the specific gravities and weights of bodies, &c. It is obvious that these may be varied infinitely, according to the purposes proposed to be accomplished.

Caliph (Arab. khalifah). Originally deputy or lieutenant, but afterwards applied chiefly to the successors of Mohammed. The representatives of the prophet of Islam, the caliph exercised a power which was primarily spiritual; and in theory therefore he claimed the obedience of all Mohammedans. In practice the claim was soon disregarded; and the Fatimite caliphs of Africa and the sovereigns of the Omniad dynasty of Spain each professed to be the only legitimate representatives of Mohammed, in opposition to the Abbasside caliphs of Bagdad. The latter caliphate reached its highest splendour under Haroun al Raschid in the ninth century; but his division of the empire among his sons showed how completely the caliph had lost sight of the spiritual theory of his office. For the last two hundred years the appellation of caliph has been swallowed up in *Shah*, *Sultan*, *Emir*, and other titles peculiar to the East.

Calippic Period. In Ancient Chronology, is a correction of the Metonic cycle proposed by Calippus. The Metonic cycle was a period of nineteen solar years, at the end of which time the new moons return again on the same days of the year. The period contained exactly 6,940 days. Now 6,940 days exceeds 235 lunations by only seven hours and a half. At the end of four cycles, or 76 years, the accumulated excess of $7\frac{1}{2}$ hours amounts to one whole day and six hours. Calippus therefore proposed to quadruple the period of Meton, and to deduct a day at the end of it by changing one of the months of 30 days into a month of 29 days. [METONIC CYCLE.] The period of Calippus is sometimes referred to as a date by Ptolemy.

Calixtines. One division of the Bohemian Reformers, who in the fifteenth century protested against the errors of the church of Rome, and maintained their independence by force of arms. After the death of Huss, his followers split into two principal parties, under the names of Taborites and Calixtines; of which the latter were the most moderate and held out chiefly on the ground of the refusal of the cup (calix) to the laity, whence they derived their name. Their hostility was at length propitiated by indulgence on this point: the church of Rome declaring expressly at the same time that the giving or withholding of the sacramental wine is a matter of ecclesiastical ordinance merely, and neither the one nor the other essential to the reception of the benefits of the eucharist. The council of Basle (1431) says: 'Sive sub una specie sive duplici quis communicat, secundum ordinationem seu observationem ecclesie, proficit dignè communicantibus ad salutem.'

The same name is given to the followers of George Calixtus, a German divine of the seventeenth century, who proposed a reconciliation

CALLITRIS

between the Roman Catholics, Lutherans, and Reformed church, on the basis of the Apostles' Creed. (Hallam's *Literary History*, part iii. ch. ii.)

Callais. The name which Damour proposes to apply to a hydrated phosphate of alumina, some personal ornaments made of which have been lately discovered in a Celtic tomb in the west of France, at Lockmariaquer in the department of Morbihan. The mineral is a species of Turquoise, nearly as translucent as Chrysoprase, and of an apple-green colour approaching to emerald-green, which appears to be produced by iron and not by copper.

This stone answers to Pliny's description of the Callais, which has been considered by modern mineralogists to be the Oriental Turquoise (hence called Callaite), a name which Damour proposes to apply only to the precious stone of a sky-blue colour, which is so much used in jewellery.

Callaite. [TURQUOISE.]

Calligraphy (Gr. *καλλιγραφία*). The art of beautiful writing. The scribes who made a profession of copying manuscripts before the invention of printing have been termed Calligraphers. Their art consisted not merely in writing, but also in embellishing their work with ornamental devices, although ILLUMINATION [which see] was also practised as a distinct employment. Among the MSS. of the early part of the middle ages which we possess, there are some sumptuous specimens of the art, written in letters of gold, vermillion, &c., and on leaves of different colours, but that fashion went early out of use; and in general it may be said, that the current writing of calligraphers diminished in beauty and in laborious minuteness, especially in Italy, during the centuries immediately preceding the invention of printing.

Callionymus (Gr. *καλλιόνυμος*, with beautiful name). A genus of beautifully spiny-finned fishes, with very small gill-openings; ventral fins under the throat, and larger than the pectorals; head oblong, flattened; eyes placed near to each other, and directed upwards; no teeth on the palate; intermaxillaries capable of considerable protrusion. They have no air-bladder. The gemmeous or golden dragonet (*Callionymus lyra*) is a British example of this genus.

Calliope (Gr. *beautiful-voiced*). In Mythology, the Muse of epic or heroic poetry.

Callitrichaceæ (Callitriche, the only genus). A small cluster of imperfectly organised water-plants, with opposite leaves and minute unequal axillary flowers so reduced in structure as to afford little indication of their affinity, and hence their position remains unsettled. By some they are considered allies of *Haloragaceæ*, by others of *Urticaceæ*; it has also been proposed on plausible grounds that they are a reduced form of *Euphorbiaceæ*.

Callitris. A genus of *Conifera*, related to *Thuja*, from which it is known by the cones consisting of from four to six woody scales, which separate one from the other, each scale

CALLORHYNCHUS

having from three to six winged seeds. *C. quadrivalvis*, a large tree of Barbary, yields a very hard, almost indestructible fragrant wood, and also the aromatic gum resin called Sandarach.

Callorhynchus. [CHIMÆRA.]

Callo. The top or rubble-bed of a quarry of stone, or ballast, which is obliged to be removed before the material is raised; it is the great source of expense in working a quarry.

Callus. In Osteology, the matter which unites the divided ends of broken bones: it is a secretion of new bony matter.

Calomel. The old chemical name of *chloride of mercury*. The word is perhaps derived from the Greek *καλός*, fair, and *μέλας*, black. It is prepared by rubbing mercury with corrosive sublimate, which forms a black mixture, which, by the application of heat, yields a white sublimate of calomel. It is much used in medicine, especially as a purgative. It consists of 200 mercury + 36 chlorine = 236 chloride mercury or calomel. Calomel is also found native, but it is a rare mineral.

Calophyllum (Gr. *καλλόφυλλος*, with beautiful leaves). The East Indian Tacamahac, greenish coloured resin, exudes from the trunk of *C. inophyllum*, a species of this genus of *Clusiaceæ*, which consists of large shining-leaved tropical trees. The timber of this species is also used for building purposes, and for mast and spars; and its seeds yield a strong-scented oil used in India for lamps. In the West Indies, a similar oil is obtained from the Calaba (*C. Calaba*), a tree producing short racemes of white sweet-scented four-petaled flowers. Other species yield edible fruits, timber, and oil.

Caloric (Lat. calor, warmth). A term applied by the French chemists to designate the matter of heat, it being assumed that the phenomena of heat are dependent upon the presence of a highly attenuated, mobile, and imponderable form of matter. [HEAT.]

Calorificient (Lat. calor, heat; facio, I make). The term is applied in Physiology to those non-nutritive materials of food, in the form of fat, starch, sugar, and gum, which are believed to be employed in the production of heat.

Calorific Rays. A term applied to the invisible heating rays which emanate from the sun, and from burning and heated bodies.

Calorimeter (Lat. calor, heat, and metrum, a measure). An instrument for measuring the quantity of heat given out by bodies in passing from one temperature to another.

Calorimeter (Lat. calor, heat, and moveo, I put in motion). This term has occasionally been applied to a peculiar form of the voltaic apparatus composed of one pair of plates of great extent of surface, the electricity of which, when transmitted through good conductors, produces intense heat.

Calosoma (Gr. *καλός*, beautiful; *σῶμα*, body). A genus of most splendid Coleopterous insects, belonging to the family *Carabida*, or ground beetles. In this genus the jaws are

CALVINISTS

toothless, or rather devoid of notches; the maxillary palpi terminate in a large joint, and the abdomen is broad. There are two British species: *Calosoma sycophanta*, so called because its grub insinuates itself into the nests of gregarious caterpillars, and feeds upon them; and *Calosoma inquisitor*. In stating on the exception which the Calosomes present among the *Carabida* in the brilliant colours which are developed in them, an explanation seems to be afforded by a difference in their habits: they frequent trees, and are more exposed to the light than their hole-and-corner congeners, the ground-beetles.

Calotropeis (Gr. *καλός*, and *τροπή*, a keel). A genus of *Asclepiadaceæ*, consisting of shrubs or small trees, common in India. One of them, *C. gigantea*, is the Mudar, the inner bark of whose branches yields a very strong valuable fibre, and whose milky juice in the fresh state is a valuable remedy in cutaneous diseases, and at length hardens into a substance resembling gutta percha. *C. procera*, a smaller plant, possesses similar properties.

Calotype or **Kalotype** (Gr. *καλός*, and *τύπος*). A term applied to the photogenic drawings obtained by the action of light upon certain salts of silver. [PHOTOGRAPHY.]

Caloyers (Mod. Gr. *καλόγερος*). Monks of the Greek Church, who follow the rule of St. Basil.

Calp. In Geology, a name given to a peculiar and impure limestone, found occasionally in rocks of the Devonian and carboniferous series in Ireland.

Calumba. The root of the *Jateorhiza palmata*. It is dried in slices of a yellowish grey colour, and is generally worm-eaten. It has a bitter and slightly pungent taste, and is very mucilaginous. Calumba root is an excellent tonic medicine.

Calumet. In Modern History, a large beautifully adorned pipe, used by the North American Indians as the emblem of peace. The first notice of the calumet among European writers is to be found in Ferdinand de Soto's account of his expedition through the southern provinces in 1470.

Calvary. A sculptural representation of the passion of the Saviour, placed upon a natural or an artificial rock, or upon an architectural base.

Calvinists. The followers of Calvin, the second great reformer of the sixteenth century, and founder of the church of Geneva. The distinguishing tenets of this celebrated theologian refer to points both of discipline and doctrine. He was the first to reject the episcopal form of church government, originally, it is said, with great reluctance, and compelled thereto by the want of regularly ordained ministers; but he afterwards maintained the exclusive divine appointment of the Presbyterian system, which since obtained favour in Scotland, and among the Protestants of France, and has had numerous adherents in this country and America. The doctrinal opinions of Calvin,

CALX

however, have not been permanently received among those who have adopted his views respecting the ministry. On the contrary, in England and Geneva, there are many Presbyterians Arminian in sentiment. It was at the synod of Dort, in 1618, that the points in dispute between the Calvinists and Arminians were most accurately distinguished, and arranged under five heads, upon which the former party asserted the following opinions:—

1. Of predestination—that all men have sinned in Adam, and are become liable to the curse; but that God has by an eternal decree chosen some from the beginning, to whom He should impart faith of His free grace, and consequently salvation.

2. Of the death of Christ—that it is a sufficient sacrifice for the sins of the whole world; and the fact that some only believe and are saved, whereas many perish in unbelief, arises not from any defect in this sacrifice, but from the perversity of the non-elect.

3. Of man's corruption—that all men are conceived in sin and born the children of wrath, and are neither willing nor able to return to God without the aid of the Holy Spirit.

4. Of grace and free will—that the influence of the Spirit upon our fallen natures does not force, but only quickens and corrects them, inducing them gently to turn themselves towards God by an exercise of their free will.

5. Of perseverance—that God does not wholly take away His Spirit from His own children, even in lamentable falls; nor does He permit them to fall finally from the grace of adoption and the state of justification.

These opinions, which were laid down at the synod of Dort, represent the sentiments of the founder of this school, and of the ancient or strict Calvinists. In modern times another class of moderate Calvinists has arisen, who differ from these in holding lower notions concerning reprobation and the extent of Christ's sacrifice. For other subdivisions among the Calvinists, see SUB-LAPSARIANS and SUPRA-LAPSARIANS.

Calx (Lat.). A name applied by the alchemists to products of combustion, especially those obtained from the metals, which were supposed to be converted into a species of earth.

Calybio. The name adopted by some carpologists for such a one-celled, inferior, one or few seeded fruit, enclosed in a cupule, as the acorn of the oak, the mast of beech, &c.

Calycanthaceae (Calycanthus, one of the genera). A small natural order of plants related to *Rosaceae*, from which they are distinguished by their imbricated sepals, and partly sterile, partly fertile anthers being turned outwards. The Carolina Allspice, *Calycanthus floridus*, used as a substitute for cinnamon, is one of them. They are all shrubs with fragrant flowers, and inhabit North America or Japan. Some of them resemble the genus *Illicium* in their flowers.

CALYX

Calyceraceae (Calycera, one of the genera). A natural order of plants related to *Compositae*, from which they differ very little, excepting that their seeds are pendulous and albuminous, and their anthers half united. The species are woody herbaceous plants, inhabiting the warmer parts of South America.

Calyculus. A diminutive of **CALYX** [which see].

Calymene (Gr. *κεκαλυμμένη*, concealed). A name devised to express the obscure nature of a genus of Trilobites (fossil crustaceans), to which it is attached, and which is distinguished from all other Trilobites by the faculty which the species possesses of rolling the body up into the form of a ball, in the same manner as the recent genera *Sphærona*, *Armadillo*, *Glomeris*, viz. by approximating the two extremes of the trunk at the under part. The anterior segment or shield of Calymene is as broad as or broader than it is long, and supports two compound prominent eyes; the posterior or terminal segment forms a sort of triangular elongate tail.

Calypso (Gr. *Καλυψώ*). In Mythology, a daughter of Atlas according to Homer, but of Oceanus and Tethys according to Hesiod, was the queen of the island Ogygia. On this island Ulysses suffered shipwreck; and Calypso, in spite of his desire to return home to Ithaca, detained him there seven years, till, warned by Hermes, she was compelled to let him go.

Calyptolite. An altered Zircon, occurring in minute short square prisms, of a dark brown or greenish brown colour, at Haddam and Middletown, in Connecticut.

Calyptrea (Gr. *καλύπτρα*, a covering). The name of a genus of Gastropods, having a patelliform shell, to the concavity of which adheres either a smaller conical shell, like a cup in a saucer, or a semicircular testaceous process, forming the commencement of a columella. The branchia consist of a single row of long and slender filaments. The foot is circular, expanded, and furnished with two anterior processes. The genus, originally established by Lamarck, forms the family Calyptreidae, composed of the genera Calyptrea, Crepidula, Pileopsis, Metopoma, Platyceras, Hipponyx, and Phorus.

Calyx (Gr. *καλυξ*, a cup). In Anatomy, is applied to that branch of the pelvis of the kidney which receives the apex of the cone or bundle of the uriniferous tubules: in man there are several 'calyces' in the kidney.

In Botany, the name given to the outermost of the enveloping organs of a flower. It is usually green, and sometimes bears a great resemblance to leaves; but it is also frequently richly coloured, as in the *Mirabilis*, *Salvia splendens*, &c. This organ appears to have the office of protecting the more tender parts lying within it, and is therefore usually present in flowers; when absent, its protecting office is always performed by some modification of bracts, as in the Arum and the Willow. If it is adherent to the sides of the ovary, it is called

superior; if partially adherent, half superior; and if quite free from the sides of the ovary, it is inferior. In systematical botany these differences are of great importance.

Cam or **Camb.** In Machinery, a contrivance for converting a uniform rotatory motion into a varied rectilinear motion. The end of a rod which is free to move only in the direction of its length is held in contact, by the action of a spring, or weight, with the edge of an irregularly shaped mass which revolves uniformly upon an axis. A varied motion is thus communicated to the rod, which carries with it the machinery by which the motion is to be applied. This contrivance is much used in the machinery for lace-making. [ROSE ENGINE.]

Cam-wood. The wood of *Daphia nitida*: the tree which yields it grows in Sierra Leone and the interior of Africa. It is used in dyeing instead of Brazil-wood, and gives a finer and more durable red.

Camaldulians or **Camaldulites.** An order of monks, under the rule of St. Benedict, founded at Camaldoli, in the Tuscan Apennines, in the eleventh century.

Camarilla (Span.). The little or private chamber of the sovereign of Spain (equivalent to the *petits appartements* of the old French régime); but the term is generally applied to his immediate confidants, who are usually all-powerful in the government of the country. In England the term is nearly synonymous with *clique*.

Camassia (Quamash or Kamas, its native name in America). A genus of *Liliaceæ*, the only species of which, *C. esculenta*, is the Quamash of the North American Indians. It bears a close resemblance to *Scilla*, having blue expanded flowers, which, however, are somewhat irregular in form. It grows in abundance on the swampy plains of the north-west parts of America; and the bulbs, which form the greater part of the vegetable food of the Indians, are there collected soon after the flowering period, a labour which devolves principally on the women. They are cooked by baking in a hole dug in the ground, and are then pounded and dried into cakes for future use.

Camber (Fr. *cambre*). The small rise which is given to a piece of framing, a roof, or an opening of any kind in a building, for the purpose of compensating for the settlement of the various parts, or for the necessary subsidence of the joints, is known by the name of *camber*. It is given in order to prevent the beam or the piece of timber or stone from becoming concave on the upper surface, either by its own weight or by the load it may have to carry.

CAMBER. In Shipbuilding, signifies a curvature upwards. A deck is said to be cambered when higher amidships than at the bow or stern. Camber is, likewise, the name for a small dock for boats and timber.

Cambium (a Low Latin word for liquid which becomes glutinous). A viscid secretion formed between the liber and alburnum of Exogenous trees in the early spring, when ve-

getation recommences. It is supposed by some physiologists to be the matter out of which new wood and bark are formed; by others to be a preparation of organisable matter, out of which the horizontal growth of the cellular system, and the vertical growth of the woody system, may be nourished during their respective development. It disappears as soon as the new wood and bark have been completely formed.

Cambogia (Cambodja, a district whence gamboge was procured). The name under which the plant yielding gamboge was formerly known. It is now more generally called *Hebradendron gambogioides* or *Garcinia Cambogia*.

Cambrian Series. The earliest fossiliferous rocks in North Wales were thus named by Professor Sedgwick many years ago. They are regarded as forming a natural basis of the Silurian series, but include also the lower member of that series. However convenient it may be found to distinguish locally between the various parts of one great series, there are no grounds for making these subdivisions the basis of general classification, and thus the Cambrian has generally been regarded as a subordinate member of the Silurian group. The determination of very large series of sedimentary rocks of much greater geological age than either Silurian or Cambrian has modified the views of geologists as to the importance of these subdivisions.

Cambrie. A delicate linen fabric, which was originally manufactured at *Cambray*.

Camel. A machine invented by the Dutch for carrying vessels into harbours where there is not a sufficient depth of water. It consisted of two large boxes, or half-ships, built in such a manner that they could be applied on each side of the hull of a large vessel. On the deck of each part of the camel a number of horizontal windlasses were placed, from which ropes proceeded on one side, and being carried under the keel of the vessel, were attached to the windlasses on the deck of the other part. When about to be used, as much water as necessary was suffered to run into them; all the ropes were then cast loose, and large beams were placed horizontally through the port-holes of the vessel, the ends resting on the camels alongside. When the ropes were made fast, and the vessel properly secured, the water was pumped out, on which the camels rose and bore up the vessel. (Beckman's *History of Inventions*, vol. iii. p. 337.)

CAMEL. In Zoology. [CAMELIDÆ.]

Camelion or **Chameleon Mineral.** Manganesate of potash, obtained by melting a mixture of potash and black oxide of manganese. When put into water the solution is first green, and passes through a variety of tints of green, purple, and red, till at length it becomes colourless.

CAMELEON. In Zoology. [CHAMELEON.]

Camelidæ (Gr. *κάμηλος*). A family of ruminant Mammalia, which deviates from the rest of the order in the presence of two incisors in the upper jaw, and the absence of

CAMELIDÆ

cotyledons in the uterus and fetal membranes. The camel and dromedary of the Old World, and the llama, guanaco, and vicuña of the New World, are the existing species of this family.

The Old-World Camelidæ (*Camelus*) are especially organised for existence in the arid and barren deserts of Asia and Africa. They have a broad, expanded, elastic foot, terminated in front by two comparatively small hoofs, and well defended beneath by a felt of coarse hair. The New-World Camelidæ (*Auchenia*) have narrower feet, and the hoofs are bent in the form of claws, adapted to climb the steep passes of the mountain ranges of South America, to which continent they are confined.

Besides the peculiar characters above mentioned, the camels present a modification in the structure of the stomach which is not present in any other family of Ruminantia. There are developed from the sides of the first cavity of the stomach or paunch two series of cells, into which experiment has proved that the water which the animal drinks almost exclusively passes, and where it can be kept apart from the solid contents of the paunch in a quantity of several quarts. Surely the final relation of such a modification of structure to the peculiar physical characteristic of the localities to which the animal possessing it is confined must force itself irresistibly on the mind. But besides a reservoir of water to meet the exigencies of long journeys across the desert, the dromedary and camel are provided with a storehouse of solid nutriment on which they can draw for supplies long after every digestible part has been extracted from the contents of the stomach: this storehouse consists of one or two large collections of fat stored up in ligamentous cells supported by the spines of the dorsal vertebrae, and forming what are called the humps. When the camel is in a region of fertility the hump becomes plump and expanded; but after a protracted journey in the wilderness it becomes shrivelled and reduced to its ligamentous constituent, in consequence of the absorption of the fat. Buffon carried his teleological reasoning, or the ascription of design, so far as to assert that the humps on the backs of the camel were badges of slavery, and intended to adapt them to the burdens of their taskmasters; and he supported this ingenious idea by the unfounded assertion that the dorsal prominences did not belong to the camels in free nature. But the true uses of the fatty humps, as of the water-cells, relate to the exigencies of the Camelidæ of the deserts under every condition. The complete adaptation of the camel for the dreary wastes in which it is destined to exist, is further illustrated by some minor modifications in its structure. The nostrils are narrow oblique slits, defended with hair at their margins, and provided with a sphincter muscle, like the eyelids; so that the animal can close them at pleasure. This action is of great service in excluding the fine and penetrating sand which is drifted along in clouds by the storms of the desert. The expanded sole of the foot, elastic

CAMELLIA

as a cushion, prevents the leg from sinking in the loose surface: the long joints and lofty tread of the camel are equally adapted for a rapid progression along loose sandy plains. Thus to the Arab of the scorching desert the camel is as valuable, and indeed as essential, as the reindeer to the Laplander in his region of perpetual snow. The one animal, like the other, serves, while living, for all the purposes of draught and burden, and supplies his master's family with milk. When dead, the flesh of the camel is eaten, though it is coarser than that of the ordinary Ruminants: its hide, which approaches that of the Pachyderms in thickness and strength, is applied to the manufacture of saddles, harness, pitchers, shields, and various other articles. The finer hair is manufactured into articles of clothing, and the coarser hair is woven into a kind of matting for the covering of tents. By day the camels transport their owner and his family, with all their property, from place to place. By night the body of the recumbent beast of burden serves as a pillow for his master; or if the air be agitated, the camels are arranged to windward, so as to form a barrier against the ever-shifting sands.

The camel is the sole medium of communication between those countries which are separated by extensive deserts; in the beautiful and expressive metaphor of eastern speech, it is 'the ship of the desert,' and in truth it is the only ship by which the wilderness can be navigated with certainty and safety. A stout Arabian camel can travel with a load of 800 pounds at the rate of about three miles in the hour. The swifter varieties, as the light dromedary or 'mahairy,' are said to carry a single rider over a space of from 70 to 100 miles in 24 hours, and that for several days in succession.

Camellia (Gr. *χαμαί*, on the ground; *λίπος*, *flax*). A cruciferous genus, one species of which, *C. sativa*, called Gold of Pleasure, is cultivated chiefly for the oil obtained from its seeds. They are dwarf annual or perennial plants, with stem-clasping leaves and terminal racemes of small yellow flowers. The oil obtained from *C. sativa* is of a clear yellow colour, and the residual cake has been recommended for cattle, but is too acrid. The stems contain a considerable proportion of fibre, and in some parts of the Continent are used for making brooms.

Camellia (so named in honour of Kamel, a Spanish Jesuit). A beautiful genus of evergreen shrubs inhabiting China and Japan. Several species are known, one of which, *C. oleifera*, furnishes the Chinese with abundance of oil used for various domestic purposes. Others are small-flowered and unimportant; but one, *C. japonica*, is among the most beautiful plants of the vegetable kingdom. It is from this that the multitudes of double varieties, now common ornaments of greenhouses in the spring, have been obtained partly by seeds and partly by the perpetuation of sported branches. Most of the varieties originated with the Chinese and Japanese; but many very fine ones have been raised in this country

CAMELOPARD

and Belgium. They are usually cultivated in pots, but are never seen in perfection unless planted in the open ground beneath a glass roof: and under such circumstances they only require to be guarded from severe frost. In some parts of England, and even near London, they are occasionally grown in the open air, but with little success.

Camelopard. [GIRAFFA.]

Camelopardalis. One of the constellations formed by Hevelius in the northern hemisphere. It is situated between Cepheus, Cassiopeia, Perseus, Ursa Major, Ursa Minor, and Draco.

Carmenae (Lat.). Divinities, worshipped at Rome, whose name, as shown by the forms *Carmentis* and *Carmenae*, was connected with *carmen* or song. The name was also applied in Roman literature to the nine Muses.

Cameo or Camaiæu. A word of doubtful origin, applied to gems of various colours sculptured in relief. The art of engraving on gems boasts of high antiquity, having been practised with various degrees of success by the Egyptians, Greeks, and Romans. It was revived in Italy in the fifteenth century, and is even at the present day cultivated with considerable success. The cameos of the ancients were usually confined to the agate, onyx, and sard, which, on account of the variety of their strata, were better suited to display the artist's talents; but they are also occasionally found executed on opal, beryl, or emerald, and even on a sort of factitious stone, the *Pitrum obsidianum* of Pliny, distinguished by the moderns as the antique paste. (*Encyclopædia Metropolitana*.) One of the most famous cameos is the onyx at present in Paris called the *apothecosis of Augustus*. It is one foot in height and ten inches in width.

Camera Lucida (Lat.). The name given by Dr. Hooke to an instrument contrived by him for making the image of any object appear on a wall in a light room either by day or by night. It is described in the *Phil. Trans.* vol. xxxviii. p. 741.

The instrument now known by the name of Camera Lucida is a very ingenious invention of the late Dr. Wollaston, for the purpose of enabling anyone, without a knowledge of the rules of drawing or perspective, to delineate distant objects, or trace the outlines of landscapes &c. with perfect accuracy. It consists of a quadrangular glass prism, *a, b, c, d*, by means of which rays of light are bent, by two reflections, into

to their previous direction. A ray of light proceeding from *O* enters the face of the prism at *a*, and continues its course in a straight line till it meets the adjacent side of the prism at *b*, and making with it a very acute angle, is wholly reflected in the direction *b c*. At *c* it again meets the side of the

CAMERA OBSCURA

prism, and is in like manner reflected in the direction *c E*. The eye being placed at *E*, sees the image of the object on the surface of the prism at *c*, and refers it to *P*, on a plane *M N*, which may be covered with a sheet of white paper. The point of a pencil can also be seen on the paper, and thus the accurate outline of the object may be traced. It is easy to see from this the proper form which the crystal should have. By the laws of optics, the size of the picture will bear the same relation to the object delineated, that the distance of the eye from the paper bears to the distance of the object. Hence, in order to increase or diminish the size of the picture, the prism is mounted in a brass frame, supported by brass tubes capable of being lengthened or shortened at pleasure. A thin brass plate, affixed to the upper surface of the prism, and having a small hole in it for the observer to look through, keeps the eye in its proper place, and procures steadiness of vision. A convex lens may be placed over the hole in the brass plate, for the purpose of magnifying the image; or a concave lens placed before the prism at *a* will adapt it to short-sighted persons. The instrument is extremely convenient, on account of its portability.

Camera Obscura (Lat.) or **Dark Chamber.** Is an optical apparatus, by which the images of external objects are thrown on a white surface, and represented in a vivid manner in their proper colours, shapes, &c. Hence the apparatus may be used for the purposes of delineation, as well as the camera lucida; but as it is from its construction less convenient, it is chiefly used for the production of images or pictures upon surfaces sensitive to light in the art of photography, and cameras of great optical perfection are now constructed for this purpose.

The common camera obscura is thus constructed: Through a convex lens, or small circular hole at *C*, the light is admitted into a darkened room or box, so that rays

proceeding from an object *A B*, and falling on a white ground within the room, paint an image of the object in it in an inverted position, *a b*. Sometimes a mirror *D* is placed in the interior of the box, making an angle of 45° with its sides, whereby the image is thrown down on the bottom of the box at *a b*, and by means of the reflection restored to its natural position. The best ground for receiving the image is plaster of Paris, formed somewhat concave. The image is viewed through an oblong aperture cut in the box. The most perfect camera obscura is formed by placing an inclined mirror in a revolving frame at the top of a building, by which the rays are thrown down on a convex lens in the roof, and the images of all the surrounding objects received on a table. The images being accompanied by the motions belonging to the objects, a very pleasing picture is formed. The invention of the camera obscura is usually ascribed to

CAMERALISTICS

Baptista Porta: it was, however, known to Friar Bacon, in the thirteenth century.

Cameralistics. The science of public finance is sometimes so called, in reference to the system adopted by most of the petty princes of Germany, who appoint certain officers, called *Kammer-räthe*, to superintend their accounts.

Camerated (Lat. camera). A term applied to the shells of certain Cephalopods which are divided by transverse partitions into a series of chambers which are traversed by a siphon. Most of the species are now extinct.

Camerlingo (same as Chamberlain). A title given to one of the cardinals who administers the principal affairs of civil government at Rome.

Cameronians. The strictest sect of Scotch Presbyterians, so called from Richard Cameron, one of the most eminent among their leaders. On his restoration in 1660, Charles II. had sworn to maintain presbytery as the existing national church in Scotland; but the idea that it was incompatible with monarchical government led him, as soon as he could, to establish episcopacy in its place. The presbyterian clergy, driven from their parishes, continued to hold meetings or *conventicles*, as they were called in contempt; and their influence increased in proportion to the stringency of the persecution employed against them. Seeing the uselessness of violent measures, Charles in 1669 granted an *indulgence* or permission to such ejected ministers as had 'lived peaceably and orderly' (i. e. had not held conventicles) to return to their parishes, if these were vacant, or to accept other preferment. A similar indulgence was issued in 1672; but the conditions which accompanied them were not agreeable to tender consciences. (Wodrow's *Church History*, 8vo. ed. vol. ii. pp. 130, 131.) The indulgence, as emanating from the king, without the sanction of the church, was held to imply in the recognition of the royal authority a principle subversive of the national covenants (*Acts of Assembly*, apud an. 1649) and of presbytery, which acknowledged no head but Jesus Christ. While the more moderate accepted it without protest, others satisfied their conscience by giving open testimony against the usurpation of authority, while others refused compliance on any terms; and these last received subsequently the name of Cameronians. (Wodrow iii. 202.) These men at once incurred the disapprobation of their indulged brothers, as well as the anger of the government. Driven mad by oppression, they became fanatical in their views, vilified those who had accepted the indulgence, stigmatised the king and government as unscriptural and Erastian, and ended by throwing off their allegiance to the king, who, they declared, had, by his breach of the covenant and other iniquities, forfeited all right and title to the crown. (Laing's *History of Scotland*, vol. iv. p. 3.) This declaration was affixed by Cameron with about twenty others, all armed, on the market-cross of Sanquhar. (Wodrow iii. 312.) They were soon afterwards (July 20, 1680)

CAMLET

surprised at Airmoss, on the confines of Ayr and Dumfries. Cameron and his brother were killed; sixteen, who were taken prisoners, were afterwards hanged; the rest escaped. The party was now led by Cargill (shortly after, taken and executed), who at a meeting of Cameronians at Torwood, near Stirling, communicated their persecutors, including the king and the duke of York. (*Hind Let Loose*, passim, Laing iv. 112, 113.) Meanwhile, the Cameronians began to act more in concert, and in 1681 took the name of *The Societies united in Correspondence*. They were now altogether separated from the indulged ministers and the general public; their meetings were confined to mountains, or to remote and secret spots. But while they continued to be the objects of an unremitting persecution, they began to disagree among themselves. Some were displeased with the *Sanquhar Declaration*; others were offended with the violence of Renwick, now at the head of their party, who in 1687 drew up the *Informatory Vindication*. The breach was never healed. Renwick was beheaded in 1688; but the revolution put an end to the sufferings of the Cameronians and to persecution for conscience' sake (*Scotch Worthies*, § Renwick, Hackston of Rathillet, &c.; *Hind Let Loose*.) At this crisis they espoused with enthusiasm the cause of the prince of Orange. A regiment of 800 Cameronians was speedily raised, and behaved with the greatest heroism at Dunkeld and other places. A regiment bearing the name still exists. (Laing iv. 194, 208, 232.) But as, when persecuted, they had never formed a very numerous sect, so now they sank gradually into obscurity. In 1743, under the Rev. J. McMillan and other leaders, they took the name of the Reformed Presbytery, and assumed the title of the Reformed Presbyterian Synod; but even so late as 1841 the synod consisted only of six presbyteries and thirty-five congregations, most of them being very small. This result may be explained by the nature of their tenets, which denied the authority of civil rulers unless they had subscribed the national covenants, and declared that the civil magistrate is bound to suppress error and encourage true religion. These opinions have been gradually modified or abandoned; and they would have no hesitation to unite with the Establishment if patronage were abolished, and the right of electing ministers vested in the people. [MACMILLANTES.]

Camisards. In French History, the Protestant insurgents in the Cévennes, after the revocation of the edict of Nantes, were so called, from having worn their shirts over their dress by way of disguise on the occasion of some nocturnal attacks. Their principal leader, Cavalier, succeeded so far as to effect a capitulation in their favour with the French government. He subsequently entered the English service, and at his death was governor of Jersey.

Camlet. A stuff or cloth, consisting of a mixture of wool and silk, or of wool and camel's hair.

Camcense. [CAMENÆ.]

Camp (Lat. *campus*, a *field* or *plain*). In the art Military, signifies the station of an army, with its artillery, baggage, and other appendages, when it has taken the field for the purposes of war. The history of camps involves that of the military art in all ages and in all countries. The Lacedæmonians appear among the first people who directed their attention to this subject. Their camps, whenever it was practicable, were of a circular form, which was said to possess the advantage that from the centre, where the general with the flower of the troops lay, help could soonest be afforded to any point menaced by the enemy. The other states of Greece, Macedonia, and Carthage adopted the same leading principle, but accommodated the form and disposition of their camps to the nature and strength of the ground which they intended to occupy. It was from the Romans that the art of castrametation first acquired any systematic regularity. The form of the Roman camp was invariably quadrangular; it was surrounded by regular entrenchments, and was so admirably arranged that each cohort, legion, and individual knew exactly the point which he ought to occupy, and the part to which instant attention should be directed in the event of alarm. The reader will find ample details and comments upon this subject in the works of Polybius and Vegetius, and in General Roy's *Military Antiquities of the Romans in Britain*. The *Penny Cyclopædia* contains an able account of the different systems of castrametation.

In ordinary language, the term is applied to any place where troops are sheltered either by tents or temporary huts, and not by permanent buildings.

Camp-sheeting. A piled enclosure, frequently erected at the foot of an embankment or a cutting in a soft or compressible formation. A camp-sheeting consists of, 1, a guide pile; 2, a whale, or a horizontal piece of timber; and, 3, a series of planks driven in, so as to enclose the space required for the foundation, usually of the thickness of three inches, though this thickness is by no means necessary. A camp-sheeting is, in fact, nothing more than an enclosure by means of a series of planks driven flatwise to the direction of the thrust, and the thickness of the planks is that of the goods most commonly obtained in the market; its object being to resist the outward thrust of the earthwork, on which it is proposed to build, under the influence of a direct load.

Campaign (Fr. *campagne*). An uninterrupted series of military operations in the field. [WAB.]

Campanile (Ital.). In Architecture, this term is properly speaking applied to a bell tower, whether it be attached to a civic or ecclesiastical building. Though the word has been adopted in the English language from the Italian, and applied to the bell towers of churches

especially, it more correctly belongs to those towers near churches, but detached from them, which may be seen in many of the cities of Italy. The principal of these are the campanile of Cremona, which is of the extraordinary height of 396 feet; that of Florence, 268 feet high, built from the designs of Giotto; the Garisendi tower at Bologna, built in 1110, and is 8 feet 8 inches out of the upright; and very near it in the same city, another tower bearing the name of Asinelli, and leaning from the perpendicular 3 feet 3 inches, but which, seen, as it always is, in company with the first, seems to lean but little. The last we shall name will be the Leaning Tower of Pisa, and it is perhaps the most remarkable of them all. It is 161 feet in height, and overhangs 12 feet 9 inches. Its general form possesses elegance, and is that of a cylinder encircled by 8 tiers of columns over each other, and each tier has an entablature. The columns and capitals are all of marble, and the upper tier is recessed back. This characteristic detail of Italian architecture has been repeated of late very successfully at Streatham and at Wilton.

Campanula (dim. of Lat. *campana*, a *bell*). A very large genus of hardy herbaceous plants and annuals, inhabiting the temperate parts of both the eastern and western hemispheres, but most abundant in the latter. They form the principal genus of *Campanulaceæ*, and have blue or white flowers, often of considerable size, on which account most of the species are favourites in gardens. The only useful plant among them is *C. Rapuncululus*, the radish-like root of which is sometimes eaten under the name of Rampton. *C. rotundifolia* is the Hair-bell or Blue-bell of Scotland.

Campanulaceæ (*Campanula*, the typical genus). A natural order of epigynous Exogens, having a valvate regular monopetalous corolla, an ovary with two or more cells, free or half-united anthers, and a naked stigma, which features distinguish it from the rest of the Campanal alliance of which it is the type. The order is an extensive one, chiefly occurring in the north of Asia, Europe, and North America.

Campeachy Wood. Logwood, the produce of *Hæmatoxylon Campechianum*, brought from Campeachy, in the bay of Honduras.

Camphene or **Camphogen.** A term applied by chemists to a hydrocarbon, composed of 10 atoms of carbon = 60, and 8 of hydrogen = 8; it is therefore represented by the equivalent number 68. It is identical with pure oil of turpentine; and camphor is its protoxide, that substance being composed of 68 camphogen + 8 oxygen; camphor is therefore represented by the equivalent number 76.

Camphor. A concrete volatile and highly odorous substance, obtained by distillation from *Camphora officinarum*, the Camphor Laurel, which is a native of China and Japan. A species of camphor is also found ready formed in the wood of the *Dryobalanops Camphora*, a tree which flourishes in Borneo and Sumatra. What is called *crude* or *rough* camphor is in

CAMPHOR, ARTIFICIAL

small grey pieces and crystals; it is purified by sublimation, and is found in commerce in circular cakes weighing about eight pounds each, white, translucent, and somewhat tough and crystalline in texture. Camphor is chiefly used in medicine: it dissolves very sparingly in water, and the solution is called *camphor julep*; it dissolves abundantly in alcohol, forming *camphorated spirit of wine*. The word is connected by Dr. Üre (*Dict. of Arts, Manufactures, and Mines*) with the Arabian name *Kamphur* or *Kaphur*.

CAMPHOR, ARTIFICIAL. A substance much resembling camphor, obtained by the action of hydrochloric acid on oil of turpentine.

Camphor Oil. A liquid which exudes when the bark of the Borneo camphor-tree is incised. It is a solution of camphor in a hydrocarbon termed *borneene*.

Camphora. A genus of *Lauraceæ*, differing from *Laurus* in its ribbed leaves, its fewer (nine instead of twelve) fertile stamens, and its four-celled anthers. One of the kinds of Camphor met with in commerce is the produce of *Camphora officinarum*, which also bears the name of *Laurus Camphora*, and *Cinnamomum Camphora*.

Camphoric Acid. An acid obtained by boiling camphor in nitric acid. It consists of 80 carbon, 8 hydrogen, and 5 oxygen; or of 1 atom of camphor and 4 atoms of oxygen.

Camphrene. A volatile liquid obtained on passing camphor vapour over red-hot lime.

Campylotropal (Gr. *κῆμυλος*, *curved*, and *τροπή*, *I turn*). In Botany, a term applied to such ovules as bend down upon themselves till their apex touches the base. They are extremely common in plants, and are more particularly those in which a raphe exists; the latter being a bundle of vessels whose office is to maintain a communication between the base of the nucleus and the base of the seed.

Canal (*canalis*, from *canna*, Gr. *κῆνα*, *a hollow reed*: whence also *gun*). An artificial channel filled with water, formed for the purposes of draining, of irrigating, of supplying towns with water, or of inland navigation. The canal by which the Lago Fucino drains into the river Liri, may be cited as an illustration of the first use; of the second, the canals with which ancient Egypt was intersected; of the third, the artificial aqueducts of antiquity, or, in modern times, the New River, by which London is in a great measure supplied by the streams from the head of the Lea, and the Canal de l'Oure, by which Paris is supplied from the valley of the Marne; but the term is usually applied to channels made for the purpose of inland navigation.

That the importance of canals as a means of inland navigation attracted attention even in the earliest ages, is manifest from the Fosse Philistina, large canals (Pliny iii. 16) at the mouth of the Eridanus in Liguria, as well as from the grand design of the Cnidians, a people of Caria in Asia Minor, to dig a channel through the isthmus which joined

CANAL

their territory to the continent. (Herod. ii. 78.) The attempt of the Egyptians, both under the Pharaohs and the Ptolemies, to unite the Nile with the Red Sea by means of a navigable canal has been often mentioned, though at the present day it is difficult to discover the least traces of its existence. The Greeks conceived the idea of making a navigable passage from the Ionian Sea into the Archipelago, by cutting across the isthmus of Corinth. This undertaking, however, proved abortive; and though the attempt was again renewed by several of the Roman emperors, it still remained without success. In the reign of Augustus, Drusus succeeded in excavating a canal from the Rhine to the Yssel, and formed, as we are told by Pliny, a new mouth from the Rhine to the Sea. A canal between the Rhine and the Maese, supposed to be that now commencing at Leyden, and passing Delft to its junction with the Maese at Sluys, was likewise formed by the Romans. But, as has often been observed, it was by bending nations under the same yoke, and not by uniting them by commercial ties, that the Romans sought to extend international communications; hence their canals were either formed for the purpose of warfare, or of draining. There can be little doubt, however, that it was the Romans who introduced, into their provinces, the models of internal communication, which in modern times have undergone such immense improvement, and which have been converted to a nobler purpose than conquest—the interchange of labour.

There is no country in the world where the advantages of canals are more appreciated than they are in China. From time immemorial the rivers that intersect that vast empire have been united by innumerable canals; and the Grand Canal is said to be the most stupendous work of the kind that has ever yet been executed. Russia, too, exhibits a remarkable degree of enterprise in the construction of canals for the purpose of inland navigation; and though innumerable difficulties peculiar to that country for a long period impeded the progress of works of this kind, that empire is now traversed by an unbroken line of water communication from St. Petersburg to the Caspian Sea.

The canals constructed during the period of the glory of Italy are very numerous, and it is said that the invention of locks originated in that country; but though many of the canals there made were navigable, their primary object seemed to have been to communicate to both banks of the Po the various productions of the country drained by its affluents.

In the Netherlands, the construction of canals commenced in the twelfth century, when Flanders became the commercial entrepôt of Europe; and to the large share which canals possess in its economical arrangements is to be ascribed chiefly the prosperity of Holland at the present day. From the structure of that country, canals are formed in it with peculiar facility; and there is not a town, or village,

CANAL

which is not furnished with a canal of greater or smaller dimensions. France has from a distant period exercised the skill of her engineers in the construction of canals for inland navigation. The first was the canal of Briare, which opens a communication between the Loire and the Seine, and thence between Paris and the western provinces, and is of immense importance in inland commerce. Omitting many works of this kind, completed, in progress, or contemplated in that country, the canal of Languedoc may be mentioned as being the first canal executed to connect two seas. It was intended to join the Mediterranean with the Atlantic, and was considered, at the time of its execution, a stupendous undertaking. It is 160 miles long, is supplied by a number of rivulets, and is provided at proper intervals with 114 locks and sluices.

A reference to the early history of Spain, Sweden, and Denmark, and to the more recent histories of Austria, Russia, and above all to that of the late United States of America, will show to what an extent those several states have endeavoured to develop their internal resources, and to distribute universally the productions of labour by means of canals of internal navigation.

It is a singular circumstance that Great Britain, generally foremost in the race of civilisation, and possessing so many natural means for the formation of canals, from its insular position and its numerous rivers, should have been the last nation in Europe to avail itself of those advantages. It is true that at different periods of our history the importance of internal navigation was deeply felt, and various expedients were adopted for removing obstructions in the rivers of England, with a view of facilitating commerce; but it was not till the middle of the last century that the construction of canals began to enter in the system of British economy. In the year 1765 an impulse was given to the construction of canals in England by the project, which was originated by the duke of Bridgewater, of forming a canal from Worsley to Manchester; a project which was altered, and extended, by three successive Acts of Parliament, to admit of greater comprehensiveness in its execution, and has formed the basis of all future plans of canalisation in this country. The example then set by the duke of Bridgewater was soon followed; the large amount of capital in England, which is ever ready to be risked in undertakings that are likely to prove advantageous, soon found its way into this class of investments, and in a short time the country became intersected with navigable canals.

The section of a canal is usually a trapezium of which two sides are parallel, and horizontal, and the other two equally inclined to the horizon, but in different directions. The inclination depends on the nature of the soil traversed. It is least in tenacious earth, and greatest in loose soil; but no soil will permanently maintain itself unless the base of the slope be to the height

in the ratio of 4 to 3; in loose soils the ratio of the base to the height may require to be 3 to 1, or even in some cases 4 to 1.

A canal is usually confined between a bank on one side and a towing path on the other, the breadth of whose upper surface must be sufficient for a road, on which the animals employed in draught may easily pass. This requires the breadth of the upper surface to be at least nine feet. The usual rule for the other bank is to make the breadth at the top equal to the height measured from the top of the canal; but in this case there should be a berm at the foot of the bank, of a foot, or a foot and a half, at the level of the top of the said canal, which tends to diminish the danger of the wash of water upon the bank. To prevent the entrance of rain-water, a counter ditch is formed on the outside of each of the banks. The profile of a well-constructed canal will therefore present the following figure:—

The dimensions of navigable canals must depend upon the size of the vessels designed to navigate them. In order that they may admit two vessels to pass one another with freedom, the breadth at bottom is made twice as great as the beam of the vessels; the depth that is required is at least one foot more than the draught of the vessels. It results from this fact that there is a great latitude in the dimensions of the canals; and the widths observed by the French government in the works of this kind, executed in that country since 1822, are the most generally approved. They are for canals of *grande navigation* 49 feet 6 inches upon the water line, and 33 feet 4 inches upon the bottom line, with a depth of about 6 feet 6 inches; the canals of *petite navigation* are only 33 feet 4 inches on the water line, and 22 feet on the bottom, with a depth of five feet; canals for steam navigation are made wider than the above.

The bed of a canal is made absolutely level, or it must have only such a slope as is required to convey water to replace that which has been wasted. Hence when a canal intersects a sloping country, in a series of channels at different levels, means must be provided to enable vessels to pass from one level to the other. This is commonly effected by means of locks; but in cases where the difference of level is very great, the trouble and expense of such an operation as passing a chain of locks is obviated by a system of passing the boats from one level to the other by the aid of steam or other machinery.

The invention of locks, as a means of carrying a canal through an undulating country, has given an entirely different character to the inland navigation of Europe from that which it had before. Various nations have claimed the

CANAL

honour of this invention; and though Italy appears the most entitled to it, the controversy which has been raised on the subject has not yet been settled. A lock is a chamber formed of masonry, occupying the whole bed of the canal, where the difference of level is to be overcome. This chamber is so contrived that the level of the water may be made to coincide with either the upper, or the lower, level of the canal. This is effected by two pairs of gates, one of which is placed at each end of the chamber of the lock. By this means, while the gates at the lower end of the chamber are opened, and those at the upper end are closed, the water in the chamber will stand at the level of the water in the lower part of the canal; and, on the contrary, when the lower gates are closed and the upper gates are opened, the level of the water in the lock will coincide with the level of the water in the upper part of the canal. In the first case a boat may be floated into the lock from the lower part of the canal; and if then the gates be closed, and water be admitted into the lock from the upper level until the surface of the lock is in a line with the water above, the boat will be floated up, and on the opening of the upper gates may be passed onwards. By reversing this course of proceeding, boats may readily be conveyed from the upper to the lower level. [LOCK.]

The supply of water required for the maintenance of the navigation on a canal depends 1st, on the *lockage*, or the quantity which is used in passing the vessels through the locks; 2nd, on the evaporation from the exposed surface; and 3rd, on the leakage. The loss of water from imperfections in the locks, and from any sudden affluence of boats in a reach of the canal, must also be taken into account. The quantity of the lockage may be estimated from the traffic return, but that required to compensate for the evaporation must necessarily differ according to the circumstances of the locality traversed by the canal. The usual calculation is that the quantity required for this purpose must be equal to $\frac{1}{16}$ or $\frac{1}{8}$ of an inch over the whole surface of the canal; and experience has shown that it is not too much. With respect to the leakage, it must depend upon the materials of which the banks are made, upon the area exposed to this action, and to the degree of saturation of their materials; but in ordinary cases it may be assumed that an allowance of two inches, upon the water surface, will be sufficient to compensate for this cause of loss. The loss consequent upon the imperfections of the locks and works must depend upon the care with which those works are maintained; it seems, however, to be admitted that, after a few years' service, a lock gate will allow 10,000 feet cube to escape in twenty-four hours, and that it is necessary to provide for that quantity. The affluence of boats in a particular reach of the canal must be appreciated by local knowledge, for there can be no law regulating it. It may be observed that, in order to diminish the loss by infiltration, the banks of a canal are

CANARIUM

puddled, or lined with a material impermeable to water. In England clay is used for this purpose; in France, on the contrary, a layer of concrete is substituted with very good results.

The advantages derived from canals are now so generally known, and acknowledged, as to render it almost superfluous to refer to the question, were it not that of late years the competition of railways has proved extremely injurious to them. In fact, the rapidity and the certitude with which the ordinary class of goods can be delivered by the latter mode of conveyance has rendered it a decided favourite in public estimation; but for heavy, cumbrous articles, the economy of water transit must always insure the preference for canals. There may be a question as to the advisability of establishing canals at the present day in new places; and, though the French government persists in making them, there seems to be every reason to believe that in so doing it is but wasting capital in unproductive works. Still, when once established, canals are able materially to advance the public interests, and to keep down the price of many kinds of goods carried over them. The only conditions of effecting this object are economy and simplicity in the system of traction, and a good mode of management so as to avoid all unnecessary delays and loss. For this purpose steam has lately been employed on the Regent's Canal, and in the river navigation of France, with considerable success; and the canal companies have in some cases taken upon themselves to do all the traction as it is performed on railways, instead of leaving it to the separate wharfingers. If these improvements be steadily persevered in, there can be no doubt of the success of the system, and canals will again become, as they long were, a source of wealth and prosperity to the country where they have been executed.

For further information on the subject of canals, the reader is referred to Phillips's *General History of Inland Navigation*; to Nichols, Priestley, and Walker's *Historical Account of the Navigable Rivers, Canals &c. of Great Britain*; to Sganzin's *Cours de Construction*; Minard's *Cours d'Architecture*, &c. &c.

Canaliculate (Lat. *canalis*, a water-pipe). In Botany, applied to leaves or other parts when the edges are so much turned upwards, or the surface is so much hollowed out, as to produce the appearance of a channel or gutter.

Canalifera (Lat. *canalis*, a canal; *fero*, I bear). The term *Muricide* is now applied to the family. The name of a tribe of Zoophagous Univalves, or Gastropods, of which the shell is characterised by a long straight canal terminating the mouth.

Canarium (Canari, its Malay name). The name of certain tropical Indian trees, of the order *Myricaceæ*, bearing compound leaves and dioecious panicle flowers. *C. commune* is cultivated in the Moluccas and Java for the sake of its fruits, which also yield an oil used

CANARY-BIRD

at table and for burning in lamps. The exudation from its bark resembles balsam of copaiba in its properties. *C. strictum* is known in Malabar as the Black Dammar-tree.

Canary-bird. Two distinct species of finch (*Carduelis*) appear to have afforded the different varieties of singing-bird familiarly known by this name. The one which is best known in its wild state is the *Carduelis canaria* of Cuvier, and is very abundant in Madeira, where its characters and habits have been observed with much attention by Dr. Heineken. The canary-bird was brought into Europe as early as the sixteenth century, and is supposed to have spread from the coast of Italy, where a vessel, which was bringing to Leghorn a number of these birds besides its merchandise, was wrecked. As, however, they were males chiefly which were thus introduced, they were for some time scarce; and it is only of late years that their education and the proper mode of treating them have been known.

Canaster. The rush basket in which tobacco is packed in Spanish America; whence *canaster tobacco*.

Cancel (Fr. canceller). In Printing, a leaf to be cut away by the bookbinder and another reprinted leaf substituted, or part of a sheet, usually indicated by a *, †, ‡, &c., in the signature.

Cancellaria. A Lamarckian genus of Trachelipod Testacea, having the shell oval or turfed; base of the aperture sub-canaliculate; canal very short; columella plicate; the plaits usually transverse, varying in number; lip internally furrowed; operculum horny. The reticulated *Cancellaria* (*Cancellaria reticulata*, Lam.) is a well-known species, from the Atlantic Ocean.

Cancellate (Lat. cancelli, *lattices*). In Botany, a term applied to leaves consisting entirely of veins, without connecting parenchyma, so that the whole leaf looks like a plate of open network. Instances of this kind occur in *Ouvirandra fenestralis*, the lattice-leaf plant, but they are extremely rare.

Cancer (Lat.). The *Crab*. The fourth sign of the Zodiac, which the sun enters about the 21st of June, when he reaches his greatest northern declination. The first point of Cancer is 90° distant from the first point of Aries, and is called the Summer Solstice. The parallel circle through this point is called the *Tropic of Cancer*.

CANCER. A disease chiefly attacking the glands, consisting of a scirrhous tumour, terminating in an ill-conditioned and deep ulcer, generally attended by excruciating pain. When the cancerous character of a tumour is once ascertained, its extirpation, where practicable, is the only chance of effectual relief. The large blue veins which ramify round a cancer of the breast were compared by old authors to the claws of a crab, whence the name of this disease.

CANCER. The Linnæan generic name for the modern Brachyurous family of Crustaceans

CANDELABRUM

Cancerinite. A silicate of alumina and soda with carbonate of lime; remarkable as an instance of a silicate containing carbonic acid as a constituent element.

It occurs in Norway, the Ural, Transylvania, and at Litchfield, in the state of Maine, in North America, both massive and in crystals. Named after Cancrin, a Russian minister of finance.

Canceroma. A genus of *Grallatores* or wading birds, belonging to Cuvier's family of *Pressirostres*, or compressed-billed waders, including only one known species, the Boatbill; so called from the form and structure of the bill, which characterises the genus. The bill is flattened or depressed, not compressed; and is composed of two boat-shaped or spoon-shaped mandibles, with their concavities applied towards each other, the upper one having a strong and sharp tooth near the point. The Boatbill inhabits the banks of the Orinoco and other large rivers of South America, which are subject to flooding in the rainy season.

Candelabrum. The Latin name for the stand, or support, on which a lamp was placed. Candelabra varied in form, and were highly decorated with the stems and leaves of plants, parts of animals, flowers, and the like. There was no article of furniture in which the ancients displayed more taste and elegance, of design than in candelabra. The etymology of the word would seem to assimilate the candelabrum to our candlestick; it is, however, quite certain that the meaning of the word *candela* was nothing more than that of a lamp, and that the *candelabrum* was a support, more or less heavy in construction, upon which the lamp was placed, or whose top was hollowed out for the reception of oil, or some other combustible. The great variety observable in ancient candelabra was not so much dependent on the caprice of the artist as on the uses to which they were first applied. Before the employment of oil, the mode of illuminating an apartment was by means of dry wood burnt on braziers (basins for holding fuel), supported by tripods. The Greeks, always delighting to preserve some reminiscence of an ancient usage, thence adhered to the triangular form in this article of furniture, and their example was followed by the Romans. Generally speaking, there are two species of candelabra: those which curled upwards in the form of a brazier, so nearly approaching the form of a portable altar as to be almost confounded with it; and those which possessed accessories and ornaments of the same character as those before described, but much higher in relief, and of marble. The first species must be classed with the tripod, and there seem to be reasons for believing that it was used only in temples and in small chapels. They were frequently sculptured in friezes, usually accompanied by genii and instruments of sacrifice. The other species seems to have been more common, and Rome furnishes numerous instances of them; but, as Winkelmann observes, not one of this kind has been found in bronze.

CANDIDATI

The marble candelabra exhibit as much variety in the form of the vase, or brazier, which it is their principal purpose to support, as in the body and base of the support itself. Sometimes they are expiscious to excess, the contrivance and design of the foliage being such as to display more skill than propriety of taste. Others, however, there are which are exquisite models of form, taste, ornament, and execution. The Museum of the Vatican contains perhaps the finest collection in Europe of this species. There is one to be seen there of 7 ft. high, resting on griffins, or lion's paws; the general form of its shaft is that of a baluster, which supports a vase-shaped basin; it is highly decorated with foliage and Bacchantes in alto rilievo. Our British Museum presents some specimens; but not of the first class. For full particulars on this subject the reader is referred to Piranesi's work, *Vasi, Candelabra, e altri Monumenti*. Lachausse thinks that the marble candelabra were used in temples more for the purpose of adding splendour to the service than of lighting it; but it seems probable that many with which we are acquainted, such as those that were found in the Baths of Titus, where numbers of apartments did not receive the light of day, actually held artificial light. The most curious specimens of candelabra, as respects form, use, and workmanship, are those found in the excavations of Herculaneum and Pompeii. They are all of bronze; and that they were employed for domestic purposes is proved from the representation on an Etruscan vase of one which serves to give light to the guests assembled round a banquet-table. They are slender in their proportions, and perfectly portable, rarely exceeding five feet in height. It is to be observed that none of the candelabra hitherto found exhibit any appearance of a socket, or of a spike, at the top, from which an inference of the use of candles could be drawn.

Candidati (Lat.). Candidates for public offices at Rome were so called, apparently, because they then appeared in public either with a white toga, or a dress with white marks. Livy (iv. 26) mentions a law, prohibiting anyone from putting white upon his dress, directed against the offence of *ambitus*, or improper solicitation of votes. By another law (Livy xl. 19) persons convicted of this offence might not become candidates again for ten years.

Candite. A kind of Pleonaste (Spinel) in which part of the magnesia is replaced by protoxide of iron. It is found in the rivers and alluvial district near Kandy (whence the name *Candite*) in Ceylon. Specimens of extremely beautiful colours are stated by Sir E. Tennent, in his work on Ceylon, to be met with at Kandy, in the bed of the Mahawelliganga (vol. i. p. 36).

Candlemas. A church festival, held on the 2nd of February, to commemorate the purification of the Virgin. The name probably arose from the number of lighted candles used in the processions of the day; or perhaps from a custom of consecrating candles on that day

CANDLES

for the rest of the year. This practice was abolished in England in the second year of the reign of Edward VI.

Candles (Lat. *canдела*, from *candeo*, *I shine*). These are an important article of manufacture, and may be composed of a variety of materials. The principal are: 1. *Wax candles*, which are made by pouring melted wax over the wicks, which, for the convenience of turning and placing them successively over the cauldron, are usually attached to the circumference of a hoop. When of a proper thickness, they are rolled smooth upon a table, and the ends are cut and trimmed. It is in consequence of this method of manufacture, that when we cut a wax candle we see that it is composed of successive layers or coats. Attempts have been made to cast wax candles in moulds, but those which are thus made never burn so well as those which are *poured*. 2. *Spermaceti candles*, or mixtures of wax and spermaceti. This material forms a very good and cleanly candle; but in consequence of its ready fusibility and hardness when concrete, it does not admit of being carried about without spilling the melted material. The fused portions also, which run down the candle, are apt to curl up and fall upon the table. 3. *Composition candles*. This term was originally conferred by a manufacturer who had a large stock of spermaceti candles on hand which were of a dirty hue, and which therefore were unsaleable; he advertised them under the above name, and they were soon disposed of, under the notion of their being composed of some new combination of materials. The term has since been applied to various mixtures; but what are now sold under the name of composition candles are chiefly mixtures of spermaceti, tallow, and a little resin, and occasionally wax. 4. *Tallow candles*, which are either cast upon the wicks in pewter moulds, or made by dipping the wicks, attached in rows to proper frames, into melted tallow. 5. *Stearine candles*. Under this term we may include cocoa-nut oil candles, and a few others made of the stearine, or what may be compared to the *spermaceti* of the vegetable oils. The stearine, or rather the *stearic acid* of tallow, is also now extensively employed for making candles.

A candle may be considered as a portable gas apparatus, and its philosophical history involves a number of very curious points, which we can only superficially advert to here. The combustible material, in a state of fusion, is drawn up in successive portions by capillary attraction into the heated part of the wick, the texture, materials and dimensions of which are matters of much importance. If the wick be too large, the candle flares and smokes, producing a peculiar suffocating smell in the room, and often wants snuffing; if, on the contrary, the wick be too small, the candle burns dimly and gutters. In the former case, unburnt carbon soon collects in the upper part of the flame, and if not removed is apt to fall into the cup of the candle, where it forms

CANDLES

a kind of second wick, rapidly melting away the tallow and disfiguring the candle, and occasionally, where candles are inadvertently left burning, falling upon the table and setting fire to any combustible within its reach. This evil may to a great extent be prevented by inclining the candle at an angle of about 45 degrees, so as to keep the upper part of the wick out of the flame. In this way the air has access to it, and the charcoal, which otherwise collects into a head, is burnt as soon as deposited. Where it is required to keep a common tallow candle burning during the night, the necessity for snuffing, and the risk of mischief, may be prevented by so inclining it; and candlesticks have been contrived for the purpose, which, though effective, are very unseemly. With good wax the wick is more easily adjusted to the wants of the flame, and the necessity of snuffing to a great extent prevented; but adulterated wax is often more troublesome than tallow. Great care is also requisite in selecting the cotton for the wicks of candles, which should be of such a nature as to leave no ash, or scarcely any, when burnt. The wick is occasionally impregnated with different substances, and sometimes so plaited as to curl out of the flame, and thus prevent the necessity of snuffing; but the details of these contrivances would be foreign to the object of this work. The following table contains the results of some experiments made by Dr. Ure, with a view of ascertaining the relative intensities of light and the duration of different candles:—

Kind		Weight in grains	Height in Inches	Candle power per Argand		
10 Mould	5h. 9m.	682	132	12.25	68.0	5.70
10 Dipped	4 36	672	150	13.00	65.5	5.25
8 Mould	6 31	856	139	10.50	59.5	6.60
6 Ditto	7 24	1160	163	14.66	66.0	8.00
4 Ditto	9 36	1787	186	20.25	80.9	8.50
Argand oil flame			512	69.40	100.0	

From the above table, it appears from Dr. Ure's experiments that one-eighth of a gallon of good oil, weighing 13 and 1-10th ounce avoirdupois, lasts in a bright Argand lamp 11 hours 44 minutes. The weight of oil it consumes per hour is equal to four times the weight of tallow in candles eight to the pound, and 3 and 1-7th times the weight of tallow in candles six to the pound; but, its light being equal to that of five of the latter candles, it appears from the above table that 2 lbs. weight of oil, value one shilling, in an Argand lamp, are equivalent in illuminating power to 3 lbs. of tallow candles, which cost about three shillings. The larger the flame in the above candles, the greater the economy of light. (Ure's *Dictionary of Chemistry*.) In reference to the comparative cost of coal gas, oil, tallow, and wax, it appears that the cost of a lamp fed by gas, and giving the light of seven candles, will be about one penny per hour; of an Argand lamp fed with spermaceti

CANICULAR YEAR

oil, about threepence; of mould candles, about threepence halfpenny; and of wax candles, about one shilling. Ninety cubic feet of coal gas, value about sixpence, will produce the light of about ten wax candles for one hour. The recent improvements in the manufacture of stearine and stearic acid have tended to bring about the almost entire disuse of common tallow and even of wax candles. Spermaceti candles still maintain their ground; but different forms of stearine and stearic acid and their congeners are now the principal bases of all candles in common use; and the general adoption of plaited wicks has led to the disuse of snuffers.

Canellaceæ (Canella, one of the genera). A small natural order of plants, consisting of South American shrubs or trees; one of which, *Canella alba*, is aromatic, and yields the Wild Cinnamon of the West Indies. The bark of this species is imported from the West Indies in quilled pieces of a pale buff colour. It has a biting aromatic flavour, and is sometimes used medicinally against scurvy. From the stamens being united in a column with the anthers sessile on the outside, an affinity has been traced with the *Clusiaceæ*; but on the whole their relationship seems to be near *Bisaceæ* on account of their one-celled ovary with parietal placentæ.

Canephores (Gr. *κανηφόροι*, basket-bearers). In Architecture, this term is applied to figures of young persons of either sex, bearing on their heads baskets containing the materials of sacrifice. They are frequently confounded with Caryatides, from their resemblance in respect of attitude, and the modern abuse of their application. [CARYATIDES.]

Canes Venatici (Lat.). The *Greyhounds*. One of the constellations formed by Hevelius, in the northern hemisphere. It is represented on the celestial globes and charts by the figures of two dogs, which are also distinguished by the names of *Asterion* and *Chara*.

Canicular Days or Dog Days. The name given to certain days of the year, during which the heat is usually the greatest. They are reckoned about 40, and are set down in the almanacks as beginning on the 3rd day of July, and ending on the 11th of August. In the time of the ancient astronomers, the remarkable star Sirius, called also *Canicula*, or the *Dog Star*, rose heliacally, that is, just before the sun, about the beginning of July; and the sultry heat which usually prevails at that season, with all its disagreeable effects, among which the tendency of dogs to become mad is not one of the least disagreeable, were ascribed to the malignant rage of the star. Owing to the precession of the equinoxes, the heliacal rising of Sirius now takes place later in the year, and in a cooler season; so that the *dog days* have not now that relation to the particular position of the *Dog Star* from which they obtained their name.

Canicular Year. The ancient solar year of the Egyptians; so called because its

commencement was determined by the heliacal rising of the Dog Star. The Egyptians chose this star for their observations, either on account of its superior brightness, or because its heliacal rising corresponded with the annual overflow of the Nile. At a very early period of history the Egyptians had perceived that the solar year contains 365½ days; for their common years consisted of 365 days, and every fourth year of 366, as in the Julian calendar.

Canines (Lat. *canis*, a dog). The pointed, often long teeth, which succeed the incisors; called *dentes canini*, or *laniarii*.

Canis (Lat. *canis*, a dog). The name of a genus of Digitigrade Mammalia, restricted in the modern systems of Zoology to the species of dog, wolf, and jackal; but by Linnaeus applied in a wider sense to include the fox and hyæna. With respect to the latter animal, its enormously developed anal scent-glands, its brief coition, and its name, indicate it to belong to the family Viverridae rather than to that of the dogs, while the prickly tongue and dentition of the hyæna approximate it to the cats. The foxes are generically distinguished from the dogs by the pupils of the eye, which during the day have the form of a vertical fissure, by their less notched upper incisors, and by their longer and more bushy tail. The true characters of the genus *Canis* are six incisors and two canines in each jaw, six molars on each side of the upper jaw, and seven molars on each side of the lower jaw, making in all forty-two teeth, of which there are twenty in the upper and twenty-two in the lower jaw. The first three molars in the upper, and the first four molars in the under jaw, are trenchant and pointing or lacerating teeth; the succeeding molar in the upper jaw is very large, with two sharp cutting points towards the outer edge, and a small tubercle on the inner side inferiorly; the others are smaller, and all furnished with tubercles. The first of these tuberculate molars in the upper jaw is very large. In all the wild varieties of the species of *canis* the muzzle is elongated, and the ears are carried erect; the tongue is unprovided with cuticular spines; the fore feet have five toes, the hind feet four only; both are armed with non-retractile claws; the œcum is cylindrical, and coiled upon itself; the anal glands are of moderate size; the coitus is prolonged. The dog (*Canis familiaris*, Linn.) is distinguished from the wolf and jackal by his recurved tail; but the varieties, as to size, form, colour, and quality of the hair, are almost infinite. The dog is the most complete, singular, and useful conquest ever made by man over the brute creation; each individual is devoted to his particular master, assumes his manners, knows and defends his property, and remains attached to him till death; and all this neither from constraint nor want, but solely from the purest gratitude and truest friendship. The swiftness, strength, and scent of the dog have rendered him man's powerful ally against all other animals, and have perhaps

mainly contributed to the establishment of society. Some naturalists think the dog is a reclaimed wolf, and others that he is a domesticated jackal; nevertheless, those dogs that have become wild again revert neither into the one nor the other species. The wild dogs, and those that belong to savages, as the dingo, resemble, it is true, the wolf in the shape of the head, their straight pricked ears, rough and thick hair, long bushy tail, and lounging gait; moreover, they never bark, but utter a sharp cry or long melancholy howl, like the jackal and wolf; yet they are plainly distinct from both. The Esquimaux dogs present the first traces of a deviation from the wild type; the figure of the legs is more determined, and their pace bolder and more rapid; still they manifest their near relationship to the wolf in their sharp nose, pricked ears, and inability to bark. The Esquimaux and the people of Kamtschatka use these dogs as beasts of draught; six or seven dogs will draw a sledge laden with eight or ten hundredweight at the rate of seven or eight miles an hour, and will easily, under these circumstances, perform a journey of fifty or sixty miles a day, when the snow is hard and smooth, and the road level.

The Newfoundland dog may be regarded as the next remove from the Esquimaux variety. These fine and sagacious animals are employed in their native island to draw sledges and carts laden with wood and fish, and to render many other useful services performed elsewhere by the horse. The readiness with which the Newfoundland dog takes the water, his aptitude to fetch and carry, and his powerful and active swimming, have been the means of preserving the lives of many human beings. Another variety of dog nearly allied to the Newfoundland breed, and belonging to the same subdivision (*Arcticus*, Linn., or spaniel tribe), has been trained by the benevolent monks of the convent situated near the top of the mountain of Great St. Bernard, to hunt out and extricate such unfortunate travellers as may have been buried under the snow-drifts or avalanches, while attempting the neighbouring dangerous pass between Switzerland and Savoy.

In our own country, the shepherd's dog offers the example of one of the purest races of the domesticated animal, and that which, in its straight ears, its hair and tail, approaches nearest to the original stock. The shepherd's dog, though outwardly resembling in many points the 'dingo,' possesses a greater cerebral development, which continues to increase together with intelligence in the spaniel and barbet. Guided by the form of the cranium, we should associate the spaniel and its immediate varieties with the shepherd's dog, the wolf dog, the Newfoundland and Mount St. Bernard dog, and the Esquimaux dogs in one family (*Synæcæ*).

A comparison of the crania indicates a closer affinity of the 'dingo' with the family *Pugnæcæ*, including the mastiff and Danish

CANIS MAJOR

dog, than with the *Sagaces*. After the pugnacious mastiff and its varieties, as the bulldog, remarkable for the shortness and strength of its jaws, come the hound, the pointer, and the terrier, in the order of cerebral development. The varieties of this family (*Venantes*) differ between themselves chiefly in the size and proportions of the limbs; the greyhound is longer and more lank, its frontal sinuses are smaller and its scent weaker.

The bandy-legged turnspits, and the small pet dogs, as the pugs, poodles, Italian greyhounds, King Charles's breed, &c., are the most degenerated productions of the genus, and exhibit the most striking instances of that power to which man subjects all nature.

With some exceptions among this latter anomalous group, all the domestic varieties of the genus *Canis* are easily and naturally referable to one or other of the three great tribes above mentioned, of which the mastiff, the hound, and the spaniel may be regarded as the several types, and which we have named *Pugnaces*, *Venantes*, and *Sagaces*, from their prominent aptitude respectively for the combat, the chase, and those more varied and complicated services which seem to demand for their fulfilment a greater amount of intelligence in our canine auxiliaries.

In all the varieties of the dog, the following circumstances in his economy are constant:—He is born with his eyes closed; he opens them on the tenth or twelfth day; his teeth commence changing in the fourth month; and his full growth is attained at the expiration of the second year. The period of gestation is sixty-three days, and from six to twelve pups are produced at a birth. The dog is old at fifteen years, and seldom lives beyond twenty.

Canis Major (Lat.). The *Greater Dog*. One of the forty-eight constellations of Ptolemy, in the southern hemisphere, and under the feet of Orion. Sirius, the brightest of all the fixed stars, belongs to this constellation.

Canis Minor (Lat.). The *Lesser Dog*. Is also one of Ptolemy's forty-eight constellations. It is in the northern hemisphere, just below Gemini. Its most conspicuous star is Procyon, of the first magnitude.

Canister Shot. [CANN SHOT.]

Canna (Gr. and Lat.). A genus of *Marantaceae*, the round hard black seeds of which, produced in a tubercular capsule, are called Indian Shot. The flowers have three outer pieces, or sepals; six inner, of which one is reflexed, which are perhaps abortive stamens; one fertile petal-like stamen with an anther on its margin, and a petal-like style, with a linear stigma.

Canna Starch. The fecula of the *Canna coccinea*, sold in the shops under the name of *Tous les mois*. It is imported from St. Kitt's, and is a good substitute for arrowroot. Its granules are comparatively large, and form an excellent microscopic object.

Cannabinaeae (*Cannabis*, one of the genera). A natural order of *Exogens*, included

CANNIBALS

in the Urtical alliance, and distinguished therein by having solitary suspended ovules, and a hooked exalbuminous embryo, with a superior radicle. The Hemp and the Hop are the only members of the order, the former inhabiting the cooler parts of India, and the latter the south-eastern provinces of Europe. They are dioecious plants, with lobed stipulate leaves, and small inconspicuous flowers.

Cannabis (Gr. *hemp*). The typical genus of *Cannabinaeae*, the only species of which, *C. sativa*, is a tall annual, with elegant palmate leaves, and altogether inconspicuous flowers; those of the female plants are succeeded by the fruits known as hemp seeds. The stem yields the valuable hemp fibre; and a resinous exudation, extending over the whole surface of the plant, is the stimulant intoxicating Hashisch, the properties of which are powerfully developed in the sunny climate of the East. [ASSASSINA.] The dried plant is sold in the Indian bazaars under the name of Bang, and the resin itself under that of Churras. It is used by Asiatics in the same way, and for the same purposes, as opium.

Cannel Coal or Parrot Coal. A variety of bituminous coal, which differs from the purer kinds of ordinary coal and jet in containing extraneous earthy matters, which render it specifically heavier than water. It varies much in appearance, but is generally of a brown or black colour, with a dull earthy to a brilliant waxy lustre. It is very dense and compact, and not easily frangible, breaking with an uneven or largely conchoidal fracture, and does not soil the fingers. When burning, it splits and crackles, without melting, and leaves 3 or 4 per cent. of ash. Being hard enough to take a polish, it is sometimes made into ornamental articles like jet; but its principal value is as a gas-coal. The name is a provincial pronunciation of the word *candle*, which has been applied to it in consequence of the bright flame with which it burns, or because the poor people of some places in the colliery districts sometimes use it instead of candles. By the Yorkshire miners it is called Branch Coal. Cannel coal is found in many of the English collieries, especially at Broseley in Shropshire, and at Wigan in Lancashire; also in the Scotch coalfields of Lanlithgowshire, and elsewhere. From the way in which it crackles or chatters in the fire, this kind of coal is commonly called Parrot Coal in Scotland.

Cannelures (Fr.). Circular grooves cut in the cylindrical part of a cylindro-conoidal shot.

Cannibals or Anthropophagi (Gr. *ἀνθρωποφάγος*, eating men). Persons that devour human flesh. The ancient authors, but especially Herodotus, have recorded instances both of individual and national addiction to this revolting practice. In the middle ages it was customary for parties engaged in hostilities to accuse each other of cannibalism; but such allegations originated more in a desire, natural, perhaps, to sworn enemies in

those rude times, of fixing upon each other the most barbarous practices, than in any actual perpetration of this deed on either side. At the present day cannibalism is practised by some of the Indian tribes of North America, the Battas of Sumatra, and, more systematically, by the inhabitants of the Fiji islands. The word Cannibal is of doubtful origin.

Cannon. This word is derived from the Greek and Latin *canna*, a *reed*, and is used to denote the tube from which missiles are projected by the force of gunpowder.

There is much difficulty in tracing the earliest history of *cannon* in this sense of the word. It is certain that fiery projectiles were thrown from tubes in warfare long before the propulsive force of gunpowder was known; and when this great power began to be recognised, the engines with which it was employed were often called by the names of other engines employed for other means of propelling missiles. Almost every nation in Europe, and some of those of Asia, claim the discovery of this force, and to have been the first to employ cannon; but this must remain an open question till some adequate contemporary voucher can be produced. The first document of this nature hitherto found is among the Ordinances of Florence, and is dated in the year 1326: it authorises the manufacture of 'canones de metallo.' After this date evidences of the use of cannon are frequent, though no picture of a cannon has yet been found in any MS. of this century. In the first half of the fourteenth century, cannon were very small, and threw arrows and little balls of lead and iron. Their manufacture was improved towards the close of the century, when we find them, under the names of *cannon*, *bombards*, *gonnes*, &c., throwing balls of all weights from one to two hundred pounds.

The earliest cannon were chiefly made of strips of wrought iron arranged longitudinally, and secured by iron hoops shrunk over them. Copper and brass guns were cast very early on the continent of Europe, but not in England till Henry VIII.'s time. In the fifteenth century large cannon were universally employed for siege purposes and the defence of towns. In the work of Valturius, *De Re Militari*, written in the middle of this century, very curious examples of cannon are figured. Towards the close of this century cannon were called after the names of cruel birds and beasts, as basilisk, falcon, dragon, culverin, &c. (Max Müller, *Lectures on Language*, Second Series, p. 229.) To this period belongs the largest cannon existing in Europe, the great bombard of Ghent, sixteen feet four inches long, and with a bore of two feet two inches in diameter. Hitherto cannon had been but little used in the field; now they began to be considered of vital importance everywhere. In the sixteenth century gunpowder was vastly improved by granulation, and cannon had to be made stronger to withstand its force.

Improvements continued to be made from time to time, but it was reserved for the present generation, by the advances made in machinery and metal working, to bring out fully the extraordinary powers of these terrible and destructive engines of war.

For the principles of the construction of cannon, their employment in war, &c., see ARTILLERY; GUN; and RIFLED CANNON.

Cannon Bone. In Farriery, signifies the single metacarpal or metatarsal bone of the horse.

Canoe. The American native name for a boat made of a single trunk of a tree hollowed out. Some canoes are made of pieces of bark fastened together; these should be properly called boats. They are of various sizes, and are generally propelled by one, or if large by two or more paddles, like wooden shovels.

Canon (Gr. *κανών*, a *rule*). A word of various significations, of which we can only enumerate the principal.

1. In cathedral and collegiate churches there are canons (*canonici*) who perform some of the services, and are possessed of certain revenues connected with them. These are, strictly speaking, *residential* canons: *foreign* canons are those to whom collegiate revenues are assigned without the exaction of any duty.

2. The laws and ordinances of ecclesiastical councils are called canons; whence the phrase Canon Law.

3. The canon of Scripture signifies the authorised and received catalogue of the sacred books. The canon of the Old Testament, as received by the Romish church, differs from that of the Protestant churches in regarding as inspired those books which we reject under the term Apocrypha. The catalogue received by the Jews themselves, which we adopt, was first enlarged by the council of Carthage to the extent in which it is held by the church of Rome, and that decision was formally confirmed by the council of Trent. In the canon of the New Testament, however, the agreement of Christian churches may be considered unanimous. There exists a series of enumerations of the sacred books of the latter covenant in the writings of the first four centuries, the general agreement of which, and the satisfactory reasons which can be assigned in most cases of omission—there are no additions—distinctly mark the universality of the judgment of the early churches in this matter.

4. In Music, a perpetual fugue. The original method of writing this was on one line, with marks thereon, to show where the parts that imitate were to begin and end. This, however, was what the Italians more particularly call *canone chiuso* (shut), or *canone in corpo*.

CANON. In Printing, a large type, seldom used except in posting bills.

Canonesses. A class of religious women in France and Germany. Their convents were termed *colleges*. They did not live in

CANONICAL FORM

seclusion. The college of Remiremont was the oldest establishment of this order in France. Similar noble monasteries still exist in Germany, and the revenues and dignities of some belong to Protestants.

Canonical Form. In Mathematics, denotes a form, usually the simplest or most symmetrical, to which, without loss of generality, all functions of the same class can be reduced. A simple illustration will suffice to explain the nature of these forms as applied to quantics; further details will be found in the papers of Messrs. Sylvester, Cayley, Hermite, and others in the *Philosophical*, and *Cambridge*, and *Dublin Magazines*. Every binary quantic of odd degree, for instance the quintic

$$(a, b, c, d, e, f \mid x, y),$$

can in general be reduced to the canonical form $u^3 + v^3 + w^3$, where each u is a linear function of x and y . In fact the six disposable constants involved in the u 's suffice in general to render the two quintics identical. Mr. Sylvester, in the *Phil. Mag.* 1861, found that u, v, w , are proportional to the three linear factors of the cubic

$$\begin{aligned} ax + by, \quad bx + cy, \quad cx + dy, \\ bx + cy, \quad cx + dy, \quad dx + ey, \\ cx + dy, \quad dx + ey, \quad ex + fy, \end{aligned}$$

which latter, on that account, has been called the *canonical*.

Quantics of an even degree above the second, have a different canonical form. That of a quartic for instance is

$$u^4 + v^4 + 6\lambda uv^2 + w^4,$$

where λ is a constant parameter.

The theory of canonical forms is of the highest importance in algebra and geometry; as yet, however, it is in an incomplete state. A good introduction to the subject is given by Dr. Salmon in his *Higher Algebra*.

Canonical Hours. Stated times of the day set apart, more especially by the Romish church, for devotional purposes. In England the canonical hours for the celebration of marriage are from eight to twelve in the forenoon, before or after which that ceremony cannot be legally performed in any parish church.

Canonisat. An auxiliary quantic, upon which depends the resolution of a given quantic to its canonical form. [CANONICAL FORM.]

Canonisation. A ceremony in the Romish church, by which holy men deceased are enrolled in the catalogue or canon of saints. The privilege of canonising was originally common to all bishops, within their respective dioceses: and was first confined to the Pope by Alexander III. in 1170. When it is proposed to canonise any person, a formal process is instituted, by which his merits or demerits are investigated. Hereupon the *beatification* of the person in question is pronounced by the Pope, and his canonisation follows upon the production of testimony to miracles performed at his tomb or by his remains. The day of his death is generally selected to be kept in his honour, and is inserted as such in the calendar. The last canonisations

CANTHARIDES

recorded in Ecclesiastical History are those by Gregory XVI. in 1839, when St. Alfonso Liguori, and four others, were so honoured; and the canonisation, by Pius IX. in 1862, of certain ecclesiastics martyred in Japan. [BEATIFICATION.]

Canopus or **Canobus** (Gr. *Κάνωπος*, the name of a place in Egypt). A bright star of the first magnitude in the rudder of Argo, one of the southern constellations. As its declination is about $52\frac{1}{2}^\circ$ south, it is not visible in our hemisphere beyond the 40th degree of latitude.

Canopy (Gr. *καπνίσιον*, a mosquito-curtain, from *κάνωψ*, a gnat). An ornamental covering over a seat of state, and in its extended signification anything which affords protection from above. In this sense, it is used to express the covering of a niche, or of a statue.

Canoxinite. A silicate of soda and alumina, with carbonate of lime, from the Miasget in the Ural. Three varieties are also found in the granite of Litchfield, in Maine.

Cant. A term used in Architecture to express the sides of a polygon turned from the spectator, or an angular deflection from a straight line which is neither in the same direction to the horizontal, or to the perpendicular, line of the base.

CANT. In Sea phrase, to turn over, or round; a cant is also a piece of wood laid on the deck for the support of a bulkhead.

Cantalite. A yellowish green variety of pitchstone, containing crystals of Glassy Felspar found at Cantal, in France.

Cantata (Ital. from *cantare*, to sing). In Music, a composition for voices, usually of some considerable length and importance.

Cantharides (Gr.). Spanish flies. The *Lytta* or *Cantharis vesicatoria*, or blistering fly. These insects are chiefly brought from Astracan and Sicily: they should be free from mould and dust, of a peculiar but not very strong or nauseous odour, and of a brilliant golden green colour. These flies furnish us with the only ready and certain means of raising an effective blister upon the skin, for which purpose they are reduced to powder, mixed with ointment or lard, and spread thinly upon a piece of leather, which is then applied to the part affected. Their operation is very different in different habits and constitutions: sometimes they produce much local pain and inconvenience, and great general excitement and irritation of the urinary organs; at others they are comparatively quiet in their action; and the blister being applied at bedtime, is found in the morning to have raised the cuticle with a large quantity of serous fluid underneath it, while the patient has scarcely been aware of its agency. The object of applying a blister is generally to transfer internal inflammatory action to the surface; and in deep-seated inflammations, and painful affections of the viscera and larger joints and muscles, they are often astonishingly effective. But blisters should not be incautiously applied: they

CANTHARIDIN

sometimes produce troublesome sores, and are followed by erysipelatous inflammation. Care should also be taken to confine them, by a margin of adhesive plaister or other means, to the part upon which they are intended to operate, as they sometimes are displaced, and give rise to awkward accidents. When cantharides are taken internally, they are violently stimulant to the urinary and generative organs.

Cantharidin. The crystalline active principle of cantharides.

Canthus (Lat.; Gr. *ὤθος*). The corner of the eye, where the upper and under eyelids meet.

Canticle. A name given to certain hymns sung in the ritual of the church; as the Magnificat, the Deus Misereatur, &c.

Cantilever. A piece of wood framed into the front, or side, of a house, and projecting beyond it, to sustain the eaves and moulding of a cornice carried upon it; they are often highly ornamental.

Canto-fermo (Ital. *firm song*). In Music, the subject song, or theme. Every part that is the subject of counterpoint, whether plain or figured, is called by the Italians *canto-fermo*.

Canton. In Geography, the French designation of certain territorial divisions; but applied chiefly at present to the twenty-two districts of which Switzerland is composed, and which, while they form a confederate union like the United States of America, are governed each by a separate judicature and particular laws.

CANTON. In Heraldry, an ordinary formed, either at the dexter or sinister chief of the escutcheon, by two lines meeting at right angles, proceeding from the top or sides of the shield. By the word canton is always understood a canton dexter, unless otherwise expressed.

Canton's Phosphorus. Sulphide of calcium, obtained by heating sulphate of lime with charcoal. It appears to absorb light on exposure and to emit it in the dark.

Cantonite. A variety of sulphide of copper, crystallising, like Galena, in cubes instead of in hexagonal crystals. It is of a bluish black colour, and has a sub-metallic lustre. It is named after Canton Mine, in Georgia, where it occurs.

Cantonment (Fr. *cantonnement*). When troops are detached, and quartered in different adjacent towns and villages, they are said to be in cantonments. In India the permanent military stations are so termed.

Canvas (Gr. and Lat. *cannabis*; Ger. *hanf*, *komp*; Fr. *canevas*). An unbleached cloth of hemp or flax, chiefly used to make sails for shipping. Besides serving for various domestic purposes and for the ground of tapestry work, canvas forms the cloth on which painters usually draw their pictures.

Cansone (Ital. from *cantare*, *to sing*). A kind of lyric poem. Adopted, with some

CAP, PERCUSSION

alteration, from the poetry of the Troubadours, it found its way into Italy in the thirteenth century. It is divided, like the Greek strophic ode, into stanzas, in which the number and place of rhymes and metre of verses respectively correspond. The last stanza, commonly shorter than the others (the epodus of the ode), is called *congedo* or *ripressa* (in old French *l'envoy*), and consisted, generally, of a valedictory address to the canzon itself. This form of poetry was adapted by Petrarch to the expression of many different veins of thought—sonorous, elevated, and heroic. The Pindaric ode, somewhat more regular than the canzon, was introduced by Chiabrera. The canzonet was a sort of canzon in short verses, a favourite form with the poets of the fifteenth century.

Canzonet or **Canzonetta** (Ital.; dim. of *canzone*). In Music, a short song. The Neapolitan canzonet has two strains, each of which is, like the French vaudeville, sung twice over. The Sicilian canzonet is in a kind of jig-time, with six or twelve quavers in the bar. Sometimes both are rondeaus, and repeat the first strain for an ending.

Caoutchouc. This valuable substance is the inspissated juice or sap of several plants. The principal supplies come from South America, and are derived from the *Siphonia elastica* (Hevea Caoutchouc), and probably from other euphorbiaceous plants. It is also furnished by *Ficus elastica* and other moraceous plants; by *Urceola elastica* and other apocynaceous plants; and by *Castilloa elastica* and other artocarpads. It is often termed *gum elastic* and *Indian rubber*. Its general properties and uses are well known. Among its more recent applications are those of elastic wove fabrics, formed of caoutchouc stretched into threads and covered with cotton; and various water-proof clothing, which is made by interposing a layer of caoutchouc between two folds of the cloth, and then forcibly uniting them by pressure. For this purpose the caoutchouc is dissolved by coal-naphtha, and in that state brushed over the surfaces which are to be united.

Caoutchouc is a compound of carbon and hydrogen; when heated it fuses, and afterwards remains viscid; when subjected to destructive distillation at a high temperature, it yields four-fifths of its weight of a highly inflammable and very light volatile oily liquid (hydrocarbon), which has been called *caoutchoucine*, and which is a good solvent of the unaltered caoutchouc. Washed sulphuric ether dissolves caoutchouc, and it is also soluble in several essential oils; but most of the latter solutions leave it in a sticky state on evaporation.

The name is also applied to the juice of *Siphocampylus Caoutchouc*, an elastic gum, very different from the caoutchouc of commerce.

Cap, Percussion. A small cylinder of copper with one end closed, and containing detonating composition. It is placed on the nipple of the musket, and ignited by the blow

of the hammer when the trigger is pulled. The invention of firing small arms by a percussion lock and detonating powder dates from 1807, but the copper cap only came into use about 1842. Fulminating mercury, mixed with chlorate of potash and antimony, is the detonating compound used in the government caps.

Capacity for Heat. Experiment shows that different quantities of heat are required to raise different bodies to the same temperature, and those substances which require the largest quantity of heat to be raised to a given temperature are said to have the greatest capacity for heat. [HEAT.]

Cape (Lat. *caput, a head*). In Geography, the extreme point of a promontory, or of that portion of land which juts out into the sea beyond the general line of the coast; as the Cape of Good Hope, the most southern part of Africa; Cape Horn, the southern extremity of America; &c. On rocky and much indented coasts, capes generally terminate in acute angles, whence they are sometimes denominated *points*; and if the portion of the land which projects is small or not high, the appellation *ness* in England, and in Scotland that of *mull*, is assigned to it, as Sheerness, the Mull of Galloway, &c.

Cape-weed. A dye lichen, called *Roccella tinctoria*, obtained from the Cape de Verdes.

Capella (Lat. *a young goat*). A star of the first magnitude, or rather a double star, in the body of the goat carried by Auriga. This star, which never sets in our latitude, is also called *a Aurigæ*.

Capers. The flower buds of *Capparis spinosa* and of some allied species, in common use as a pickle.

Capias ad Respondendum (Lat.). In Law, formerly a writ for the commencement of personal actions to arrest a party at large or already in custody of a sheriff.

Capias ad Satisfaciendum (Lat.; shortly called *ca. sa.*). In Law, a judicial writ of execution which issues out on the record of a judgment, where there is a recovery in the courts of Westminster, of debt, damages, &c. By this writ the sheriff is commanded to take the body of the defendant in execution. This is the highest execution which can be had against a defendant, and no other can be afterwards had against his lands or goods, unless he die in custody.

Capibara. The largest known Rodent quadruped. It is of aquatic habits, and frequents the rivers of South America. It is the type of the genus *Hydrocharus*, signifying 'water-hog,' by which name it is sometimes known.

Capillaire. Simple syrup flavoured with orange flowers, or orange-flower water, generally goes under this name, which is derived from the mucilaginous syrup directed in old Pharmacopœias to be made of the *Adiantum Capillus Veneris*.

Capillamentum (Lat. *a head of hair*). An old name of the filament of a flower. [FILAMENT.]

Capillary (Lat. *capillus, hair*). A term applied in Botany to bodies which are long and slender, like a hair.

Capillary Action. When a very narrow glass tube, open at both ends, is inserted in a vessel containing water, the water immediately rises in the tube, and remains suspended at some height above its level in the vessel. If the same tube is plunged into mercury, the mercury in the tube stands at a lower level than in the vessel. These effects are most conspicuous when the width of the bore of the tube is so small as to resemble a hair whence the cause of the phenomena has been termed *capillary action*.

The operation of the same forces which cause the elevation of water and depression of mercury in glass tubes, gives rise to a multitude of other phenomena with which everyone is familiar. If a piece of sugar, or sponge, or blotting paper is brought into contact with water at one extremity, the fluid immediately passes through it and moistens its whole substance. A mass of wetted thread or cloth, hanging over the edge of a basin from the water within it, will empty it as a siphon would. The rise of the oil in the wick of a lamp, of the sap in trees, the functions of the excretory vascular system in plants and animals, depend on the same causes.

Capillary Vessels. In Anatomy, the minutest ramifications of the arteries and other vessels.

Capillitium (Lat. *capillus*). A kind of purse or net in which the spores of *Trichia* and similar fungi are retained.

Capital (Lat. *capitalis, belonging to the head*). This term is used in various ways, to express the relation of a head or chief. Thus the seats of government or municipal administration are called capital cities or towns. Capital crimes are those which render a criminal liable to the punishment of death.

CAPITAL. In Architecture, the head or the uppermost member of any part of a building; but it is generally applied in a restricted sense to that of a column or pilaster of the several orders, as in the figures here given, in which it will be seen that the Tuscan capital (No. 1)

consists of an abacus or square shelf on the top, and thereunder an ovolo or quarter round, and under that a neck terminated by an astragal or fillet, which latter is always considered as part of the column itself. The Roman Doric capital (No. 2) here given has an abacus, ovolo, and neck, like the last, and also in addition three amulets under the ovolo and a cyma or ogee, with its fillet above the abacus: the Grecian Doric, however, has only a square abacus and small fillets. The Ionic capital (No. 3)

consists of three leading parts; an abacus composed of an ogee and a fillet; a rind which forms the scrolls or volutes; and an ovolo and astragal at the lower part. The Corinthian and Composite capitals (Nos. 4 and 5) consist of an abacus of a peculiar form, and are decorated with leaves.

The capitals of mediæval art are quite as characteristic of the styles which then prevailed as the classical examples; and the capitals of the tenth, eleventh, twelfth, thirteenth, and fourteenth centuries may be as correctly described as those of ancient art. They usually consist of a square abacus, with foliage arranged in a circular form underneath; and often the foliage is made to assume the form of an octagon or a duodecagon immediately under the abacus, which is modified accordingly. There is, however, more of fancy in the treatment of the capitals of the middle ages than in the capitals of the classical orders, as may be seen by a reference to the article upon this subject in the *Glossary of Architecture* by Mr. Parker, or to the publications of the Architectural Publication Society under the title of a *Dictionary of Terms*. It may suffice here to say that the capitals became more ornate in proportion to the development of art; and that they gradually increased in complication as mediæval architecture approached its apogee.

CAPITAL. In Political Economy, that portion of the produce of labour saved from immediate consumption which is employed to maintain productive labourers or to facilitate production. [POLITICAL ECONOMY.] In Commerce, and as applied to individuals, capital is understood to mean the sum of money which a merchant embarks in any undertaking, or which he contributes to the common stock of a partnership.

Capitation (Lat. *capitatio*). A tax imposed on the population by the head; e.g. on every one, or every male, above a certain age, &c. [POOR TAX.] In France, the ancient capitation is now replaced by personal and other direct contributions.

Capite (Lat.). In Feudal Law, tenure *in capite* (Ang. *in chief*) signifies a direct holding of the king, the ultimate sovereign, without the intervention of any mesne lord. In England, tenants in capite were either by knight-service or socage; which were converted into common socage by the Act 12 Ch. II. c. 24, abolishing feudal tenures. [TENURE.]

Capite Censi (Lat.). In Roman Antiquity, the lowest rank of Roman citizens; so called because, as having no taxable property, they were counted simply by *heads*, as were the Proletarii, who received their name merely as adding to the population of the state.

Capitol (Lat. *capitolium*). By this name is generally known the great temple of Jupiter on the Tarpeian mount at Rome. There were such capitols in other cities, as at Capua.

Capitulation. In its original sense, a writing drawn up in several *capitula* or heads.

In the language of Military Law, the articles of surrender, when a garrison or other force surrenders to an enemy on terms, and not at discretion. In Ecclesiastical History, articles sworn by bishops and other prelates on admission to their dignities were styled Capitulations. So also was the oath, tendered first to Charles V., and then to the emperors of Germany who succeeded him, by the electors, termed the Election Capitulation (*wahl-capitulation*).

Capitulum (Lat. *dim. of caput, a head*). A close head of sessile flowers, as seen in the *Composite* and some other plants.

Capivio Acid. A resin found in balsam of capivi.

Capnomancy (Gr. *καπνομαντεία*, from *καπνός*, smoke, and *μαντεία*, prophecy). Divination by smoke was practised among the ancients, both by throwing on the fire seeds of poppy and other herbs, and observing the figures which might be fancied in the smoke; and by observing the smoke of sacrifices.

Capnomor. An oily substance of a pungent and rather agreeable odour obtained from the tar of wood.

Capo d'Opera (Ital.; Fr. *chef-d'œuvre*). A masterpiece. *Capi d'Opera*: Masterpieces.

Caponnière (Fr.). In permanent Fortification, a passage leading from one work to another, protected on each side by a wall or parapet, generally of earth, sloping to the bottom of the ditch. When a passage is thus protected on one side only, it is called a demi-caponnière.

In Field Fortification, a double stockade covered with planks and earth at the angles of the ditch is called a Caponnière; it serves to give a flank fire in the ditches.

Caporiclanite. A hydrated silicate of alumina and lime found crystallised and in radiated laminae at Monte Caporiciano near Florence and several other localities in Tuscany. It has a flesh-red colour, a pearly lustre, and is only transparent in very thin laminae.

Capparidaceæ (Capparis, one of the genera). A natural order of Exogenous plants, belonging to the Cistal alliance, and having tetramerous flowers, stamens not tetradynamous, exalbuminous seeds, and closed fruit. They consist of annuals, perennials, bushes, and trees, inhabiting the warmer parts of the world. They have all a powerful pungent or even acrid taste, and have been in some cases used as substitutes for the common mustard; in others they have proved severe poisons. In general their flowers are very beautiful, on account not only of their size, but of their long silken stamens, which are often gaily coloured. The common Caper-bush, a native of rocky places in the north of Europe, is a species of the genus *Capparis*, and yields the flower-buds which, pickled in vinegar, are sold in the shops as an agreeable sauce for various dishes.

Capped Quartz. A kind of Quartz crystal which is found in Cornwall, embedded

CAPRELLA

in compact Quartz. On breaking the investing matrix, the crystals are revealed, and a cast in intaglio of their pyramidal terminations is obtained, which constitutes the 'capping' which has given rise to the name applied to this variety of Quartz. The French mineralogists call this variety *Quartz encapuchonné*.

Caprella. A genus of Crustacean animals belonging to the order *Lemodipoda*, found commonly on seaweed. Montagu, who describes a species of this genus in the seventh volume of the *Linnean Transactions*, says the female differs in possessing several plates or valves beneath the body, situated between the two pairs of fins, the use of which is to carry and protect its eggs or young; at which time they extend very considerably, and form a kind of pouch distended with ova, fifteen or twenty of which are easily distinguished between the transparent plates. In this part a very strong pulsation is visible. While examining a female under a water-microscope, the author was surprised to observe not less than ten young ones crawl from the abdominal pouch of the parent, all perfectly formed, and moving with considerable agility over the body of the mother, holding fast by their hind claws and erecting their heads and arms. The characters of the genus, or rather family (*Caprellidae*), are, body of narrow linear form; eyes composite, and placed behind; legs long and slender, and variable in number, the last joint of the second pair being often toothed on the under side.

Capreolus (Lat.). The old botanical name of the tendril of a plant, for which the term *cirrhus* is now preferred.

Capric Acid (Lat. *capra*, a goat). One of the volatile acids of butter obtained by saponifying it with soda, adding excess of sulphuric acid, and distilling: it passes over mixed with butyric acid, and with two other acids, namely, the *caproic* and the *caprylic* acid. Capric acid has a mixed odour of acetic acid and of a goat. The odour of caproic acid is less gouty, and that of caprylic acid resembles perspiration. A curious relation exists between the formulæ of these several acids, the carbon and hydrogen successively increasing by the addition of 4 equivalents, as shown in the following table:—

Butyric acid	. . .	C ₄	H ₇	O ₂	HO
Caproic "	. . .	C ₆	H ₁₁	O ₂	HO
Caprylic "	. . .	C ₈	H ₁₅	O ₂	HO
Capric "	. . .	C ₁₀	H ₁₉	O ₂	HO

Capriccio (Ital. *whim, fancy*). In Music, a term applied to certain pieces, wherein the composer gives way to his fancy, without confining himself to particular measures or keys; they are also called *Fantasia*.

Capricornus (Lat. *capricornus*). The name of one of the three divisions of Tetramerous beetles; including those which have the antennæ filiform or setaceous, and generally exceeding the length of the body; eyes lunate, and enclosing the base of the antennæ; jaws very robust, with short palpi; thorax often

CAPROMYS

spined at the sides; the three basal joints of the tarsi dilated, and cushioned on the under surface; the third deeply cleft at the extremity, and receiving the minute ball at the base of the slender and long terminal joint. This division comprehends four great families—*Prionida*, *Cerambycida*, *Lamiida*, and *Lepturida*; and corresponds very nearly with the Linnean genera *Cerambyx*, *Necydalis*, and *Leptura*. The offices of the capricorn beetles in the economy of nature is to restrain the excessive multiplication of vegetable species in the warmer climates of the globe. The larvae reside within the wood or beneath the bark of trees.

Capricornus (Lat. *The Wild Goat*). The tenth sign of the Zodiac, which the sun enters about the 21st of December, at the winter solstice. The parallel circle passing through the first point of this sign is called the *Tropic of Capricorn*.

Caprification (Lat. *caprificatio*). A fertilisation of flowers by the aid of insects, in the way which occurs in the case of the fig, by means of a small fly.

Caprifoliaceæ (Caprifolium, one of the genera). A rather large natural order of Exogenous plants, belonging to the Cinchonall alliance, and having exstipulate leaves, epipetalous stamens, straight anthers bursting longitudinally, and consolidated fruit. They consist of twining and erect shrubs, and herbaceous or woody plants, and even of trees, with simple or pinnated leaves, and flowers of most dissimilar forms, but all monopetalous. The most common plants belonging to this order are the Woodbine, the St. Peter's Wort, the Tartarian and Fly Honeysuckle, the numerous species of *Viburnum*, and the Elder-tree.

Caprifolium (Lat. *capra*, a goat, and *folium*, a leaf). The genus to which the wild Honeysuckle (*C. Periclymenum*) belongs. It consists of twining shrubs inhabiting the northern hemisphere exclusively, and in most cases having long tubular flowers of singular sweetness. Many species are known to botanists, the most interesting of which are those from the north of India, China, and Japan, celebrated for their fragrance.

Caprimulgus. [NIGHT-JAR.]

Caproic Acid (Lat. *capra*, a goat). One of the acids formed during the saponification of butter; it has a rank goat-like odour.

Caproic Alcohol. A colourless aromatic volatile liquid occurring in small quantity in brandy.

Capredlene. A light colourless liquid of unpleasant odour. It is a frequent product of the destructive distillation of fatty bodies.

Capromys (Gr. *κᾰρπος*, a boar, and *μῦς*, a mouse). The name of a genus of Rodent Mammalia, exclusively confined to the island of Cuba, where they go by the name of *Hitiús*. They have four molars on each side of the jaw, in which the enamel is so folded as to form three angles on the outer margin and one

CAPROS

on the inner, in the upper teeth; the reverse in the lower teeth. The liver is remarkably subdivided in the rodents of this genus.

Capros (Gr. *a boar*). A name applied by Lacedædæ to a subgenus of Acanthopterygious fishes, which he separated from the dories (*Zeus*), and of which the boar fish (*Zeus Apor*, Linn.) may be regarded as the type. A specimen of this fish has been taken at Mount Bay, and another near Bridgewater, but it is rare as a British species.

Caprylic Acid. A constituent of butter and other fats. It is most easily prepared from cocoa-nut oil. At ordinary temperatures it is a liquid, but at 50° crystallises in needles.

Caprylic Alcohol. The hydrated oxide of capryl. A colourless volatile liquid of agreeable odour: obtained on distilling castor oil with caustic potash.

Capsaicine. An acrid soft resin found in the fruit or seed pods of the *Capsicum annuum*. It appears to be the acrid principle of Cayenne pepper.

Capsicum. A genus of *Solanaceæ*, consisting of annual or sub-shrubby plants, with a wheel-shaped corolla, five convergent protruding anthers, and a two to four celled ovary becoming a membranous pod or seed-vessel of varied form. The seed-vessels of different species, namely the larger ones of *C. annuum*, and the smaller ones of *C. frutescens* and *C. baccatum* or Bird-pepper, as well as those of other species, form, when powdered and sifted, the Cayenne pepper of commerce, so well known as a powerful condiment, and often useful as a stimulating medicine. Cayenne pepper is often grossly adulterated with common salt, and occasionally red lead and earthy powders are said to be added to it: it often has a disagreeable rancid odour, owing to its being sprinkled with oil to prevent its dust affecting those who prepare it. The fruit of the various species is often called Chili, from Tchitli, the native Mexican name.

Capell. The upper horizontal beam in the timber framing of viaducts or bridges: this word seems to be incorrectly used for 'sill,' which means properly the bottom piece of a framing, but the other application of the word has become sufficiently general to warrant its being noticed.

Capequarres. The metal fastenings which keep the trunnions of a gun in their places on the carriage.

Capstan (Fr. *cabestan*: the word is connected by Mr. Wedgwood, *Dictionary of English Etymology*, with the old Spanish *cabra*, an engine for throwing stones, and with the Latin *capra*, a goat, applied to machines for raising weights). A strong massive

piece of timber round which a rope is coiled, and being turned by means of bars, or levers, it affords an advantageous mode of applying power to overcome an obstacle. The capstan is chiefly employed in ships, where it is used for weighing anchor,

CAPTAIN

hoisting sail, &c.; it is generally placed vertically, the lower end resting on a pivot, let down and firmly bolted through the deck of the ship, and the levers inserted in holes in the head or top, so that the force of the men working the capstan may be exerted continuously, and that there may be no necessity for removing the levers from one hole to the other, as is the case when the machine is placed horizontally, as in the French 'chèvre,' used for hoisting heavy loads quickly. The power of the capstan may be materially increased by the adoption of a system of wheelwork, an improvement which has been for several years applied in the mercantile and royal navies.

Capsular Ligaments. Those ligaments which surround movable articulations and retain the synovia, as in a bag.

Capsule (Lat. *capsula*, dim. of *capsa*, a box or case). In Anatomy, a membranous sac investing an organ, as the capsule of the liver, the spleen, &c. Those flask-shaped sacculi from which the uriniferous tubes commence are called 'capsules of Malpighi:' they surround the capillary glomerules or plexuses, called 'corpuscles of Malpighi.'

Capsule. In Botany, a term applied to all dry fruits which are dehiscent, whether they are many-seeded or few-seeded, simple or compound; and in such cases some expletive is added to indicate the particular nature of the fruit. Thus a capsule is *circumscissile* when cut round by a circular line dividing it into two parts; *siliquiform*, when long and taper, like the pod of a mustard-plant; *baccate*, when the pericarp is succulent; and *trilocular*, when a dry capsule bursts into three separate closed pieces. Sometimes, for special carpological purposes, the word is limited in its application to such dry compound fruits as open by valves, and have an indefinite number of seeds; as in *Digitaria*, *Scrophularia*, the common lilac, &c.

Capsula. In Chemistry, a small shallow evaporating vessel or dish.

Captain (Fr. *capitaine*; Ger. *hauptmann*, a headman or chief). In the Army, the commander of a troop of cavalry or of a company of infantry or battery of artillery. The price of a captain's commission is different in the different branches of the British service: in the life guards, for instance, it is 3,600*l.*; in the cavalry, 3,200*l.*; in the foot guards with the rank of lieutenant-colonel, 4,800*l.*; in the infantry, 1,800*l.* The full pay of a captain in the life and foot guards is 1*l.* a day, in horse regiments 1*l.* 7*s.* 6*d.*, and in the infantry 1*l.* 7*s.* 6*d.*

Captain. In the Royal Navy, is the title of the officer next in rank below a flag officer. The title of post-captain, which was the proper rank of captain, and answered to colonel in the army, has been for some time in disuse. The captain is next in rank above the commander: he rises by regular succession to the rank of rear-admiral; under the condition, however, that he must have served six years in a sea-going vessel with the rank of captain. The senior captain on any station where there is

no admiral, has the rank of commodore. The pay of a captain varies by seniority from 30*s.* to 20*s.* a day, with command money ranging, according to the rating of his ship, from 12*s.* to 5*s.* a day. His half-pay begins at 10*s.* 6*d.* a day, and rises by seniority to 14*s.* 6*d.* a day. A captain in the navy ranks with a lieutenant in the army, until he has held the rank three years: and after that time with a colonel.

The heads of small parties or gangs of men in certain stations of the ship are also called captains; as of the fore-castle, the tops, &c.

Caption (Lat. *capitio*). In Law, a certificate signed by commissioners, to testify their execution of any commission in law or equity. Also, the act of taking a man into arrest. The caption of an indictment is the designation of the style of the court before which the jurors make their presentment.

Capuchins. [ORDERS, RELIGIOUS.]

Caput Mortuum (Lat.). The inert residue of the distillation and sublimation of different substances. When sulphate of iron, for instance, or green vitriol, is distilled at a red heat, it leaves a residue of red oxide of iron, which the old chemists called *caput mortuum vitrioli*. These residuary products were represented in alchemical writings by the symbol of a death's head and cross-bones.

Capybara. In Zoology. [CAPIBARA.]

Car (Lat. *carrus*, Fr. *char*). Any rude cart. The Irish car is a one-horse cart, with very low broad wheels, used for carting out manure and carting home grain in the case of soft peaty soils. The Irish jaunting car is a kind of one-horse chaise, commonly without springs, in which the people sit back to back, and with their faces looking sideways.

Carabides (Lat. *carabus*; Gr. *καρᾶβος*, the stag-beetle). A family of Pentamerous beetles, characterised by having a bilobed upper lip, smooth jaws (maxillæ), an entire tooth in the centre of the notch of the mentum or chin-process, and dilated tarsi in the males. The majority of the British species have the elytra soldered together. The *Carabides* generally defend themselves by discharging from the extremity of the body an acrid fluid, and emit a fetid odour. They are amongst the most ravenous of beetles, and prey on other insects, for which they lurk beneath stones, the bark of trees, &c.

Carabine or **Carbine** (Fr. *carabine*, Ital. *carabino*). A firearm used by cavalry and artillery, shorter in the barrel than the infantry musket or rifle. The 6th Dragoon Guards, from their having in early times been armed with this weapon, are called 'The Carabineers.'

Carabine-à-tige (Fr.). Is a rifle used in the French service, which has an iron pin fixed at the end of the breech in the line of the axis; on this, the bullet, which is elongated, is forced down by a hard blow of the ramrod, and so expanded into the groove.

Caractères de Civilité (Fr.). In Printing, cursive characters invented and used by the printer Granjon, of Lyons, in the middle of

the sixteenth century. Béranger de la Tour's *L'Amis des Amis* is an example of this kind of type.

Carades Sandstone. A deposit originally described by Sir R. Murchison as one of the principal members of his lower Silurian *Carades*, but now subdivided and less important. The lower and larger member passes into the LLANDEILO FLAHS, which are exceedingly rich in fossils, and the upper member is found to lie in many places unconformably on the lower. This upper member includes the *graptolite schists* of Sweden, the *Ungulite beds* of Kuusla, the *Ampelites schists* of Brittany, &c. All these deposits are singularly rich in TRILOBITES.

Caragana (Carachana, the Mogul name). A genus of pretty hardy Leguminous shrubs, inhabiting the Russian dominions in Asia. *C. arborescens*, *Altagana*, and *Chamlagu* are common in the shrubberies of this country, where they flower in the months of June and July. *C. jubata* is a singular scrubby plant, with the branches closely covered by the leafy spiny ragged petioles. The leaves of *C. arborescens* are said to contain a blue colouring matter like indigo.

Carageen or **Carraheen**. The Irish name of *Chondrus crispus* and other similar alga, of which large quantities are collected for feeding cattle and for making jelly for invalids.

Carappa (Caraipe, the name of one of the species in Guiana). The celebrated balsam of Tamacuari, a substance of the colour of old port wine and the consistency of olive oil, and of great utility in the cure of the itch, is the produce of *C. fasciculata*, one of several South American species of the genus of *Ternstroemia*.

Caraites. A sect among the Jews who adhere closely to the text and letter of the Scriptures, rejecting the rabbinical interpretations and the Cabbala.

Carambols. [BILLIARDS.]

Caranna. A resin brought from South America, of an aromatic odour; formerly used in plaisters.

Caranz (derivation unknown). A genus of spiny-finned fishes, belonging to the *Scomberidae* or mackerel family: but differing from the true mackerel in having a series of scales, with ridges or keels in the middle, ranged along the lateral line. From this resemblance they are commonly termed 'bastard mackerel.'

Carapa (Carib. *Carapa*, applied to one of the species). A genus of *Meliaceæ*, found in the West Indies and tropical America. *C. guianensis* is a large tree of Guiana. Its bark is febrifugal, and used for tanning. Its timber, called crab-wood, is employed as mast-spars, shingles, &c.; and the oil of its seeds, called carap or crab-oil, is used for burning in lamps and other purposes. In this country it hardens into a solid fat. The seeds of *C. guianensis*, a native of tropical Africa, yield Ocoodi or Talli-coonah oil, which is purgative and anthelmintic.

Carapace (Fr.). The upper shield or plate of the armour or shell of the tortoise and

CARAPINE

crab. Callipash is a corrupt form of this word.

Carapine. An alkaloid found in the *Carapa guianensis*.

The bony vault which protects the upper part of the body of the Chelonians, or tortoises and turtles, and which results from the union by suture of the dilated and flattened parts of the vertebrae and ribs, intercalated with bones from the dermoskeleton. The analogous part of the body of the crab is also called Carapace; but this is not composed of corresponding parts to those of the tortoise, but of a calcified integument. The term CARAPACE is also used (which see).

Carat (a word of doubtful origin). A carat is a weight of 4 grains, used in weighing diamonds. The term Carat is also used in reference to the fineness of gold; in expressing which, the mass spoken of is supposed to weigh 24 carats, of 12 grains each; and the pure gold is called *fine*. Thus, if gold be said to be 22 carats fine (or standard), it is implied that 22-24ths are pure gold, and 2-24ths alloy. In the process of assaying gold, the real quantity taken is very small, generally from 6 to 12 grains; and this is termed the *assay pound*. It is subdivided into 24 carats, and each carat into 4 assay grains, and each grain into quarters; so that there are 384 separate reports for gold. When the gold assay pound is only 6 grains, the quarter assay grain only weighs 1-64th of a grain. This will give an idea of the accuracy required in the weights and scales used for such delicate operations. [ALLOT and ASSAY.]

Caravan (a Persian word). A company of merchants, travellers, or pilgrims, who associate together in many parts of Asia and Africa, that they may travel with greater security through deserts and other places infested with robbers or exposed to other dangers. The commercial intercourse of Eastern and African nations has from the remotest ages been carried on chiefly by means of caravans, as the governments that have sprung up in those continents have seldom been able, even if they had had the will, to render travelling safe or practicable for individuals. Since the establishment of the Mohammedan faith, religious motives, with others of a less exalted character, have tended to augment the intercourse between different parts of the Eastern world, and to increase the number and magnitude of the caravans. Mohammed, as is well known, enjoined all his followers to visit Mecca once in their lifetimes; and large caravans assemble for this purpose in every country where the Mohammedan faith is established. There are four regular caravans which proceed annually to Mecca: the first from Damascus, composed of pilgrims, travellers, and merchants, from Europe and Asia; the second from Cairo, for the Mohammedans of Barbary; the third from Zibith, near the mouth of the Red Sea, where those of Arabia and India meet; the fourth from Babylon, where the Persians as-

CARBOBENZOIC ACID

semble. Every caravan is under the command of a chief or aga (caravanbachi), who has frequently under him such a number of troops or forces as is deemed sufficient for its defence. When it is practicable they encamp near wells or rivulets, and observe a regular discipline. Camels are almost uniformly used as a means of conveyance, in preference to any other animal, on account of their wonderful patience of fatigue, and their peculiarity of structure, which so admirably fits them for travelling through desert wastes. [CAMEL.] For further details on the subject of caravans, the reader may consult M'Culloch's *Commercial Dictionary* and the authorities there referred to.

Caravansary (Pers. *serai*, a house for caravans). A large public building, or inn, for the reception and lodgement of caravans in the desert. Though serving instead of inns, there is this essential difference between them, that the traveller finds nothing in the caravansary for the use either of himself or his cattle, but must carry all his provisions and necessities with him. Caravansaries are also numerous in cities, where they serve not only as inns, but as shops, warehouses, and even exchanges.

Caravel (Span. *caravels*). A light ship formerly used by the Spaniards and Portuguese; also a vessel used by the French in the herring fishery.

Caraway. The carminative fruit or seed of the *Carum Carui*, an indigenous umbelliferous plant. English caraways are more plump and aromatic than the Dutch or foreign, which are apt to be mouldy and of little flavour. They yield about 3 per cent. of essential oil when carefully distilled with water. They are good addition to purgative and other remedies, to prevent griping and flatulency; but their chief consumption is among gingerbread bakers, confectioners, and pastrycooks.

Caraway, Oil of. An aromatic volatile oil, obtained on distilling the crushed seeds of the *Carum Carui* with water. It is used as a flavouring agent.

Carbamide. A compound of carbonic oxide and amidogen, contained, according to Regnault, in chlorocarbonate of ammonia: its chemical formula is CO, NH₂.

Carbanillic Acid. *Anthranilic Acid*. A crystalline body derived from indigo by the action of caustic potash.

Carbanilide. Carbamide in which hydrogen is replaced by phenyl. A white, volatile, crystalline body.

Carbazotic Acid. A crystallisable acid and bitter substance, composed of carbon, azote, and oxygen; obtained by the action of nitric acid on indigo and some other vegetable and animal substances. It is the bitter principle of Welter.

Carbthyllic Acid. *Carbovinic acid* or *thylcarbonic acid*. An organic acid produced when carbonic acid is passed into alcoholic solution of potash.

Carbobeazotic Acid. A derivative of sinnamein said to differ from benzoic acid.

CARBOLIC ACID

Carbolic Acid. A substance obtained by the distillation of coal-tar: it crystallises in prismatic needles, which fuse at 98° and boil at 270°: it has a penetrating odour and burning taste, and in many respects resembles creosote: its specific gravity is 1.06. It appears to be identical with the substance called *hydrate of phenyl*. Its formula is C_6H_5O, HO .

Carbomethylic Acid. Obtained as carbethylic acid, wood spirit replacing vinic alcohol.

Carbon (Lat. *carbo*). This term is used in Chemistry to signify the pure combustible base of the varieties of charcoal and other carbonaceous matters; the diamond is pure carbon in a crystalline form. Carbon is an elementary substance, which combines with oxygen in two proportions, forming *carbonic acid* and *carbonic oxide*.

Carbonates. Salts containing carbonic acid. They are recognised by the effervescence which is excited when they are put into dilute muriatic acid. *Carbonate of lime* is one of the most important of these compounds, forming the varieties of marble, limestone, calcareous spar, chalk, &c. Carbonate of lime consists of

Lime . . . 1 atom	=	28	. . . 56
Carbonic acid 1 atom	=	22	. . . 44
1		50	100

Carbonate of potash and carbonate of soda are also important salts. [POTASH; SODA.] *Carbonate of ammonia* is used in medicine; it is a white pungent salt, commonly known under the name of *smelling salt*. *Spirit of hartshorn* is a solution of impure carbonate of ammonia, obtained by distilling bone or horn.

Carbonic Acid. This important compound is obtained when any form of carbon, such as the diamond or pure charcoal, is burnt in oxygen gas. It consists of 6 carbon + 16 oxygen = 22 carbonic acid; or of

Carbon . 1 atom . 6	. . . 27.27
Oxygen . 2 atoms . 16	. . . 72.73
1	22 100.00

100 cubical inches of carbonic acid gas weigh 47.3 grains. Under a pressure of 36 atmospheres, at the temperature of 32°, it becomes liquid; and when the pressure which retains it in the liquid state is removed, the rapidity of the evaporation, and the sudden and enormous expansion of the vapour, are such as to produce a degree of cold under which the acid solidifies, forming a white concrete substance possessed of very extraordinary properties. Mr. Faraday was the first who liquefied carbonic acid, but it was first described as a solid by M. Thilorier.

At common temperatures and pressures water absorbs its own volume of carbonic acid; under a pressure of two atmospheres it dissolves twice its volume, and so on. Carbonic acid imparts briskness and a slightly pungent and sour taste to water impregnated with it; it also confers the effervescent quality upon many mineral springs. Carbonic acid is recognised by its rendering lime-water turbid. It extinguishes flame and suffocates animals; hence the miners call it *choke damp*. Carbonic acid is contained

CARBONIFEROUS SYSTEM

in marble, chalk, and all the varieties of limestone, from which it is extracted by strong heat, as in the process of *burning lime*; or by the action of stronger acids, in which case the carbonic acid escapes with *effervescence*. Mountains of limestone, therefore, are great natural repositories of carbonic acid. This gas is also produced during the respiration of animals, and is evolved in the process of fermentation.

Carbonic Oxide. A gas composed of

Carbon . 1 atom . 6	. . . 42.8
Oxygen . 1 atom . 8	. . . 57.2
4	14 100.0

100 cubical inches weigh 30.2 grains. It is fatal to animals, and extinguishes flame; but it burns in contact with air, and forms carbonic acid. It is obtained by passing carbonic acid over red-hot charcoal; or by heating a mixture of chalk or pounded marble and iron or zinc filings to redness. It is not absorbed by water.

Carboniferous (Lat. *carbo*, coal, and *fero*, I bear). A Geological term generally applied to beds or strata containing coal.

Carboniferous System. The deposits thus named are among the most important of all the accumulations of mineral matter in the earth; for they include, in England, not only the great deposits of coal and iron, which are sources of national wealth of inconceivable magnitude, but some of our principal ores of lead and zinc, supplies of marble, an inexhaustible supply of limestone for building and burning, and a number of less important, though very valuable minerals.

There are two principal divisions of the carboniferous system. Both are characterised by the presence of an enormous quantity of carbon; but in one—the lower division—the carbon is in combination with oxygen and lime, forming masses of limestone derived chiefly from animals; and in the other—the upper series—the carbon is more nearly pure, and in the form of coal, the result of vegetation. [COAL.]

The chief characteristic of the lower and older member of the carboniferous system in England and Western Europe generally, as well as in North America, is a vast deposit of coralline limestone, crystalline for the most part, and abounding in shells, encrinurites, and corals. It has long been known as the *MOUNTAIN LIMESTONE*, from its large development in the mountain districts of Yorkshire, Derbyshire, and Lancashire, where it is the source of much picturesque beauty. [MOUNTAIN LIMESTONE.] Among the limestones are many bands of coal, some thick enough and good enough to pay for working. In other parts of England, and in Russia, very poor and imperfect coal measures represent the carboniferous limestone. In Ireland there is a peculiar sandy deposit of the same age.

Over the carboniferous limestone lies the *MILLSTONE GIRT*, a rock occasionally represented by bituminous shales and covered by pebbly grits. Here come in some of those valuable deposits of iron more common among the coal measures, but helping to give value to

CARBOY

the middle part of the carboniferous system. Here also are valuable building stones.

The natural divisions between the beds of limestone and its numerous crevices and caverns are often filled more or less completely with ores of lead and zinc. Rich masses of galena occupy the fissures, large deposits of calamine fill the interspaces between the beds, and where none of these valuable minerals exist, large bodies of water accumulate and occasionally make their way out in springs or are available when tapped by accident or intention.

Much of the carboniferous limestone is of organic origin, and appears to have been deposited in a coral sea, not far from islands covered with luxuriant vegetation. The almost perfect identity of species observable when fossils obtained from the quarries in Central Europe are compared with others from high northern districts either in Europe or North America, renders it highly probable that a remarkable uniformity of climate prevailed at that time over the whole northern hemisphere. The nature of the prevailing fossils—*Goniatites*, *Orthoceras* &c. among the univalves, and the numerous species of *Terebratula* and *Spirifer* among the bivalves—points to conditions different from any that have since affected the same districts.

Over the millstone grit come the sandstones and shales that contain the coal measures—the lower part of which in England is most prolific in coal. At least a quarter of a million of square miles of the earth's surface in the various tracts of land now above the water, are covered with sandstones and shales of the carboniferous period, among which coal is buried; and this coal is for the most part accessible. As in each square mile of country there are upwards of three millions of square yards of surface, and a cubic yard of coal weighs nearly a ton, while in many coal-fields there is an average of workable coal from ten to twenty yards thick, the reader may obtain for himself a rough but sufficient estimate of the possible extent of supply of this mineral. [COAL.]

Carboy. A large globular bottle of green glass protected by basket-work. Carboys are seldom used, except for containing certain acids and other highly corrosive liquids likely to act upon stoneware. A carboy of oil of vitriol usually contains about 160 lbs. of that acid, or twelve gallons of water. This word is identified by Dr. Latham with the Romaic *καρμυρία*, the π being sounded as *b*, and the κ as *y*.

Carbuncle (Lat. *carbunculus*, a small coal). The name applied by jewellers to the variety of Precious Garnet which is cut *en cabochon*. It was a gem held in great estimation by the ancients. [ALABANDINE; PYROPE.]

CARBUNCLE. A hard circumscribed inflammatory tumour, which generally arises on the neck or back, soon forming a fetid discharge, and acquiring a tendency to gangrene. It is a kind of malignant boil, spreading under the

CARCASS

skin, and producing a morbid inflammatory action of the surrounding parts. Poultices, and free incisions to let out the matter, and afterwards emollient fomentations, are the most effective remedies. This disease is also called *anthrax*, the Greek word for a coal.

Carburet of Sulphur. A liquid compound of carbon and sulphur, obtained by passing the vapour of sulphur over red-hot charcoal. It was formerly termed *alcohol of sulphur*. It forms compounds, which have been termed *carbo-sulphurets*.

Carburets. In Chemistry, the generic term for compounds of carbon with the simple combustibles.

Carburetted Hydrogen. Under this term two gaseous compounds of carbon and hydrogen are usually included: *light hydrocarbonate* and *olefant gas*.

Light carburetted hydrogen is evolved abundantly in some coal mines, where it is known under the name of *fire damp*, and is the cause of those tremendous explosions which were so frequent before the invention of the safety lamp by Sir H. Davy. It is also evolved by the mud at the bottom of stagnant waters, where it results from the decay of vegetable matter. This gas is much lighter than atmospheric air, 100 cubical inches weighing between 17 and 18 grains. It burns with a yellow flame, is inodorous, and not absorbed by water. It consists of 6 carbon + 2 hydrogen. When mixed with three volumes of oxygen, or with eight or ten of common air, it explodes with great violence when inflamed, and produces water and carbonic acid.

Olefant gas received its name from its property of forming, when mixed with chlorine, a liquid of an oily appearance. It is obtained by distilling a mixture of alcohol with twice its bulk of sulphuric acid, and may be collected over water, which, however, absorbs about one-eighth of its volume of the gas. It has a slight odour; it extinguishes flame; is unrespirable; burns with a dense white light; and when mixed with three or four volumes of oxygen, or ten or twelve of air, it detonates on the approach of flame with great violence. It is nearly of the same specific gravity as atmospheric air; and from the quantity of oxygen required to convert its elements into carbonic acid and water, it is shown to consist of two atoms of carbon and two of hydrogen, or of one volume of carbon vapour and two volumes of hydrogen, so condensed as to form one volume of olefant gas.

Carcass (Fr. *carcasse*). A species of shell filled with a composition the flame of which is extremely powerful and nearly unextinguishable. Carcasses are much used in the bombardment of towns, for setting fire to shipping, &c. They can be fired from guns, mortars, and howitzers like common shells, from which they differ only in being cast thicker, that they may withstand the intensity of the fire of the composition, and having three vents instead of one fuse-hole.

CARCERES

Carceres (Lat.). In Architecture, the cells at the end of a circus in which were stationed the chariots and horses that contended for the prizes, so that they might be able to start simultaneously at the given signal.

Carcerauli (Lat. dim. of *carcer*, *a prison*). A name given by botanists to such fruit as that of the lime-tree, which consists of a small number of dry indehiscent few-seeded cells cohering round a central axis.

Carcinoma (Gr. *karpinoma*, from *karpis*, *a cancer*). A cancerous tumour.

Cardamom (Gr. *kardamum*). The seed of the *Elettaria Cardamomum*, which are imported from India. There are several varieties, but those pods which are small, short, thick, and heavy, are preferred. The seeds themselves are very pungent and aromatic, while the containing capsule is quite insipid. Their chief use is in medicine, especially in combination with cathartics and bitters. They yield an essential oil by distillation, to which their virtues are to be ascribed.

Cardan's Formulae. [CUBIC EQUATIONS.]

Cardiac (Gr. *kardia*). Belonging to or connected with the heart. The superior opening of the stomach is called the *cardia*, or *cardiac end*, from its proximity to the heart.

Cardiææ or Cardiacæ. A numerous and beautiful family of lamellibranchiate dimyary bivalve molluscs, including those species in which the mantle is open anteriorly for the foot, and also has two distinct orifices, one for respiration, the other for excretion, as in the cockle (*Cardium edule*). The shell is characterised by having at the hinge irregular primary teeth, both in form and situation, and generally accompanied by one or two lateral teeth. The genera composing this family are *Cardium*, *Hemicardium*, *Lithocardium*, *Serripes*, *Adacna*, *Conocardium*.

Cardialgia (Gr. *kardia-yla*). Anxiety and pain about the region of the stomach, frequently attended by a sense of gnawing and heat, and hence called *heartburn*. It is a common symptom of indigestion, and accompanied by salt and acid eructations. After excess in eating and drinking, a fit of heartburn may often be prevented by a teaspoonful of carbonate of magnesia, taken in cinnamon or soda-water, at bed-time; twenty or thirty grains of bicarbonate of soda in cold chamomile tea is also an effective preventive. Where the disease is symptomatic of organic mischief, these antacid remedies must be cautiously administered.

Cardinal (Lat. *cardinalis*, from *cardo*, *a hinge*). An epithet implying importance; in which sense it is applied to the principal virtues, the four points of the compass, &c.; and in theological language originally to parish churches, as distinguished from chapels and oratories: whence it was transferred to the clergy who ministered in such churches. In later times the epithet was restricted to the seven bishops of Rome, and the sees within its territory, and the clergy of the eight-

CARDIROID

and-twenty principal churches of that city: whence the college of cardinals takes its origin. The number of which this college consisted has varied in the course of time. It has for some centuries been limited to seventy; of whom six are bishops of certain Roman dioceses; fifty, styled cardinal-priests, hold their titles from parishes in Rome (many of them being at the same time bishops of foreign dioceses); and fourteen are deacons. But in point of fact there are at present fifty-eight only. The election of the pope, which is performed by these personages assembled in conclave, is thus concurred in by the three orders of clergy through their representatives. The period at which this election was confined to the cardinals is variously stated. Some have asserted that such was the case as early as 1058; others, not before 1562. It is now understood that the pope must be chosen from this body. The cardinals are distinguished by a scarlet hat, and a short purple mantle worn over the rochet. Their rank is next to that of the pope, for whom they form a political council for the secular affairs of Rome; and also an ecclesiastical council, each congregation being presided over by one or more of the cardinals. Authentic information as to their rank and function may be found in the *Papal Calendar* (*Annuario Pontificio*), published annually at Rome. [CONSISTORIUM and CONCLAVE.]

Cardinal Points (Lat. *cardo*, *a hinge*). In Geography, the east, west, south, and north points of the horizon. In Astrology, the cardinal points are those of the rising and setting of the sun, and the zenith and nadir. [COMPASS.]

Cardioid (Gr. *kardiaioûs*, *like the heart*). An algebraic curve, so called from its resemblance to a heart. It is generated by adding to and subtracting from the radii vectores through a point in the circumference of a circle a portion equal to the diameter of the latter. Its polar equation therefore is

$$r = 2a(1 + \cos \theta)$$

if a be the radius of the generating circle. Its equation in rectangular coordinates may obviously be written in the form

$$[(x-a)^2 + y^2 - 3a^2]^2 = 4a^3(a + 2x);$$

whence it may be concluded that the curve is of the fourth order and third class, having three cusps, one at the origin and the other two at the circular points at infinity. The line $2x + a = 0$, parallel to the ordinate axis, is a double tangent, and the only one which the curve possesses. It has no proper double points or points of inflexion. Amongst other properties possessed by the cardioid, the following are worthy of note. It is the pedal of a circle with respect to a point on the circumference, and the inverse of a parabola with respect to the focus. It may be generated as an epicycloid by making a circle roll on the convex side of an equal circle; consequently, like all epicycloids, the evolute of a cardioid is itself a cardioid. Lastly, this remarkable curve is the

CARDITIS

caustic by reflexion from a circle in whose circumference is a luminous point.

Carditis. Inflammation of the heart.

Cardeem. *Oynara Cardunculus*. A kind of artichoke.

Cards, Playing. Oblong pieces of pasteboard, inscribed with certain figures and points, and used in various games of skill and hazard. The origin of this invention is obscure. While it has by some been erroneously attributed to the Romans, by others it has been traced, perhaps with more plausibility, to an Asiatic source. The claim, advanced by Mezerai, on behalf of the French, is certainly untenable. Cards may have been used in France in 1390; but that they were not invented to amuse Charles VI. is evident, from the fact that they are mentioned in the Stadtbuch of Augsburg for the year 1276. Tiraboschi speaks of them as used in Italy before the close of the thirteenth century; and the game is noticed in many German books throughout the fourteenth century. The figures of the four suits were symbolical representations of the four great classes of men; and the names attached to these figures in this country arose from a misapprehension of the names originally assigned to them. Thus, by the *hearts* are meant the *gens de chœur* (œur), the choirmen or ecclesiastics, and hence these are called *copas*, or chalices, by the Spaniards; whose word *espada*, sword, indicating the nobility and warriors of the state, has been corrupted into the English *spade*. The clubs were originally *trèfles*, trefoil leaves, and denoted the peasantry; while the citizens and merchants were marked by the diamonds (*carrreaux*, square tiles). The word *knave* (Ger. *Knabe*, boy) was used, of course, in its older sense of servant, or attendant on the knights. The French cards long retained the names of the four kings, David, Alexander, Cæsar, and Charles, who marked respectively the Jewish, Greek, Roman, and Frank empires. The queens, Argine, Judith, Esther, and Pallas, are not so easily accounted for. The first name furnishes an anagram of *regina*, or queen; the others may have been chosen as types of the moral qualities of wisdom, purity, and courage.

A modern English pack of cards consists of fifty-two cards, in four *suits*—two red, *hearts* and *diamonds*, and two black, *spades* and *clubs*; each suit consisting of three *court* or *picture* cards, the king, queen, and knave, and ten other cards distinguished by the number of their 'pipe' or spots, from ten to one respectively. The lowest of these is always called the 'ace,' and the two and three are often called the 'deuce' and 'tray.' The natural rank of the cards in each suit is, king highest, and so on down to ace lowest; but in many games this rank is varied, as in Whist, where the ace is put highest of all, above the king; in *Ecarté*, where it is put between the knave and the ten; and in *Bésigue*, where it is made the highest, but where the ten is put between it and the king. In *Quadrille*, the rank of some of the

CARICA

cards is variable every hand. Sometimes the pack of cards is reduced to thirty-two, by excluding the six, five, four, three, two, of each suit; it is then called a 'piquet pack.'

An immense variety of games are played with cards, some involving chance only, some combining chance and skill, the best of them furnishing very agreeable and intellectual amusement. Some are *round games*, in which any number of persons may join, as *Vingt-un*, *Speculation*, *Loo*, *Pope Joan*, &c.; some are for four persons, as *Whist* (the best of all, and a very fine game), *Quadrille*; some for two, as *Piquet*, *Écarté*, *Bésigue*, *Cribbage*; and, lately, games have been introduced even for one person, called *Patience*. For descriptions of the several games, see these words.

Carduelis (Lat. *carduus*, a thistle). A genus of Conirostral Perchers (*Insectores*) or Passerine birds, of the finch tribe (*Fringillidæ*), including the goldfinch (*Carduelis elegans*), aberdevine (*Carduelis spinus*), and other British siskins, the habits of which are less arboreal than those of the true finches, and which feed principally on the seeds of the thistle and other composite plants. [CANARY-BIRD.]

Carrening (Fr. *carène*, from Lat. *carina*, the keel). The laying of a ship over to get at leaks or injuries in the bottom. This is commonly called *heaving down*. To careen implies also to *heel* or lie over generally. Heaving down is never practised with a large ship, except where there are no docks, and the great forces which must be applied to the mast-heads to get her over are liable to strain the hull.

Caret (Lat. *it is wanting*). In Grammar, a character in this form A, denoting that something has been omitted, and is interlined.

Carlama. [DICHOLOPHUS.]

Caribbean Sea. The southern portion of the great ocean gulf between North and South America is thus named. It is bounded by the north shores of South America and the shores of Central America as far as Yucatan, and beyond that by the coasts of Cuba and St. Domingo. To the east it is nearly shut in by the chain of the Antilles, terminating in Trinidad. It contains more than a million and a quarter square miles of water.

The Caribbean Sea receives some important rivers from South America. It has also a marine current which sets into it from across the Atlantic. Its waters accumulate, owing to the set of this current, and are forced to pass into the gulf of Mexico, whence they can only escape by the narrow passage between Florida and the Bahama reefs [MEXICAN GULF], thus forming the GULF STREAM.

The Caribbean Sea is entirely intertropical: its waters are very warm, and its depth is generally between 500 and 1,000 fathoms. It contains the important island of Jamaica. There are no coral reefs in it, except along part of the south coast of Cuba. Its bed is occasionally disturbed by earthquake action.

Carica. The Papaw-tree, *C. Papaya*, is the most remarkable species of this genus of

CARICATURE

Papayaea, and is a small tree, with a soft spongy stem, large deeply-lobed leaves having gashed segments, and unisexual flowers succeeded by oblong dingy yellow fruit. Throughout the West Indies the juice of this tree, or an infusion of its fruit or leaves, is reputed to possess the remarkable property of causing a separation of the muscular fibre of animal flesh, and thus rendering the toughest meat tender. The unripe fruit is pickled, the ripe fruit preserved in sugar.

Caricature (Ital. caricatura, from caricare, to load or overcharge). In Painting, an exaggerated representation of any object, in which any natural defects are overcharged, so as to make it appear ridiculous.

Caricium (Lat. carex, sedge). A genus of land snails, so called from their habit at sedge, wet leaves, grass, &c. Of these sedge-shells, *Caricium minimum* is British, and may be found about Acton.

Caries (Lat.). A decayed bone or tooth.

Carillon (Fr.). A tune performed upon bells.

Carina (Lat. the keel of a boat). In Botanical language, the sharp thin back of any organ. The back of a leaf folded up, if thin and sharp, the winged rim that occupies the back of certain fruits, and the sharp-backed part of a glume or bract, all bear this name. It is also applied to the two anterior petals of a Papilionaceous flower, which adhere by their lower edges into a body something like a boat.

Carinaria (Lat. carina). A genus of Heteropodous Molluscs, characterised by having the principal viscera, comprising the heart, liver, branchiæ, generative organs, &c., protruded from the body, and encased in an extremely fragile, beautiful, sub-transparent, symmetrical, compressed shell. The summit of the shell is slightly involuted, but never enters the aperture; the convexity of the shell is terminated by a single keel.

Carinate (Lat. carina). In Zoology, when a surface has a longitudinal elevated line, like the keel of a vessel.

Carinthine. A ferruginous and aluminous kind of Hornblende, from the Sau-alp in Carinthia. It occurs massive and disseminated, of a black or greenish black colour, opaque, with a lustre which is resino-vitreous externally, but internally splendid.

Carinithite. [WULFENITE.]

Carlings. In Shipbuilding, are short beams running fore and aft, with their ends scored into the great transverse beams. They aid in sustaining the deck, and in binding the principal beams together.

Carludovicia (in honour of Charles IV. of Spain, and his queen Louisa). The hats known as Panama hats are made from the leaves of *Carludovicia palmata*. Those of the best quality are plaited from a single leaf without any joinings, and as the process sometimes occupies two or three months, the price is very high. The leaves are cut while young, and the stiff parallel veins removed, after which they are slit into shreds but not separated at the stalk

CARNELIAN

end; they are then immersed in boiling water, and bleached in the sun. *Carludovicia* is a small genus of *Pandanaceæ*, confined to tropical South America.

Carmelite. [ORDERS, RELIGIOUS.]

Carmidine. An alkaloid contained in the distillate of shale-tar.

Carmintives. Medicines which allay flatulency, and pain of the stomach and bowels, arising from it.

Carmine. A brilliant lake, made of the colouring matter of the cochineal insect combined with alumina and a little oxide of tin.

Carmine Spar or **Carminite**. An anhydrous arsenate of lead and iron, occurring in translucent needle-shaped crystals, and in spheroidal forms with a columnar structure, at Horhausen in Saxony. The name has reference to the colour of the mineral, which varies from carmine to tile-red.

Carmine Acid. *Cochinellin*. The pure colouring matter of the cochineal insect. It combines with bases forming uncrystallisable salts.

Carnallite. A hydrated chloride of potassium and magnesium which occurs in coarse granular masses mixed with the rock-salt of Stassfurth, near Magdeburg in Prussian Saxony. A deposit of this salt has recently been found at Stassfurth, overlying the rock-salt of the Zechstein formation. Carnallite is used as a fertiliser of the soil, and is named after M. von Carnall.

Carnat (Lat. caro, carnis, flesh). The name given by Breithaupt to a red variety of Lithomarge from Roehlitz in Saxony.

Carnation (Lat. caro, carnis, flesh, from their colour). A favourite garden plant, obtained by the florist's art from the wild *Dianthus Caryophyllus*. Its flowers are deliciously fragrant; and although in the unimproved state they are of a uniform deep red, they have been rendered beautifully striped and variegated by successive changes in the hands of the breeder. Carnations are arranged in three classes, *flaks*, *bizarres*, and *picotees*: the first have two colours in their flowers, and broad stripes; the second have irregular spots and stripes, and not fewer than three colours; the last have a broad or narrow edging of scarlet, red, or purple, upon a white or yellow ground.

Carnations. In Painting, the parts of a picture which represent the naked limbs, &c.

Carnea (Gr.). A festival observed in most of the cities of Greece, and especially at Sparta, in honour of Apollo, surnamed Carneius.

Carnelian (Lat. carneus, from caro, flesh). A variety of Chalcedony, generally of a clear bright-red tint, and passing into common Chalcedony through greyish red gradations. The change is insensible from red to white Carnelian through flesh-red and blood-red, with a greater or less admixture of brown to orange and various tints of yellow.

The finest specimens are brought from Arabia, and from Cambray and Surat in India.

CARNIVAL

Both in ancient and modern times it has been much used for seal-stones, beads, and other ornaments. (Bristow's *Mineralogy*, art. 'Carnelian,' p. 64.)

Carnival (Ital. *carnavale*). A festival celebrated with much merriment and revelry in Catholic countries, and especially at Rome and Venice, during the week before the commencement of Lent; deriving its Italian name probably from the farewell to flesh or meat which introduces the great fast of the church.

Carnivora (Lat. *feeding on flesh*). The second tribe of Cuvier's order *Fera* (*Carnassiers*), including those species of which the teeth are peculiarly adapted for destroying living prey, and for tearing, dividing, or brushing flesh. They have incisors in each jaw, two long and pointed canines; and the molars are never beset with small conical points or tubercles, as in the insectivorous tribe of the same order. The carnivorous tribe is divided into those which tread on the sole of the foot (*Plantigrades*), and those which run on the last joints of the toes (*Digitigrades*).

Carob-tree. The Algaroba or Locust-tree, *Ceratonia Siliqua*. Its sweet and fleshy pods have of late years been largely imported for use as cattle food.

Carocolla. (a word made up of the Lat. *caro*, *flesh*, and Gr. *κόλλα*, *glue*). A genus of land-snails, so named from the tenacity with which their fleshy foot adheres to limestone rocks. The variegated carocolla (*Car. lapicida*, Lam.) is a native species, and has been found on Juniper Hill, Box Hill, Surrey.

Caroliathine. A mineral somewhat resembling Mellite, found in a bed of mineral coal at the Königen-Louise mine near Gleiwitz in Upper Silesia. It occurs in rounded balls or massive, of a colour passing from honey-yellow to wine-yellow, and is subtranslucent, has a faint greasy lustre, and is very brittle.

Named after the prince of Carolath.

Caramel. Sugar melted till it acquires a brown colour and exhales a peculiar odour.

Carotid (Gr. *καρῳτιδης*). An artery of the neck. There is one on each side of the cervical vertebrae which supply the head with blood. If these vessels are tied, the animal becomes insensible; hence the term, from *καρῳ*, *I put to sleep*.

Carotine. A deep red crystallisable substance contained in carrots.

Carp. [CYPRINUS.]

Carpadellium (Gr. *καρπός*, *fruit*, and *δηλος*, *plain*). A little-used name, applied in Botany to indehiscent, many-celled, inferior fruits, with a single seed in each cell; as in Umbelliferous or Apiaceous plants.

Carpal Bones (Lat. *carpus*, *wrist*). The bones of the wrist. They are named as follows: First row, *scaphoides*, *lunare*, *cuneiforme*, *pisiforme*. Second row, *trapezium*, *trapezoides*, *os magnum*, and *unciforme*. They are formed in an arch, so as to resist accidental fracture.

Carpathians. This singular mountain chain forms a crescent-shaped ridge, which extends

CARPENTRY

east and north of the course of the Danube, whose river valley chiefly separates the mountains of this group from the eastern continuation of the Alps on the one side, and from the westernmost extension of the Caucasus on the other. [ALPS and CAUCASUS.]

The Northern Carpathians and also the Eastern mountains are lofty dividing ranges, and attain an elevation exceeding 8,000 feet, which is about the snow limit in this part of Europe. These separate Hungary from Poland, and the plains of the Danube from those of the Dniester. They are wall-like, with only a few comparatively high passes, and form a continuous chain.

The southern part of the Carpathian chain extends to the left bank of the Danube, the river crossing the chain by a very deep gorge, and the mountain continuing towards the Adriatic. This part of the chain is less lofty than the northern part, but has two picturesque mountains which are covered with snow till long past midsummer.

The Carpathians are poor in botanical interest, but rich as a zoological province. They also abound in minerals.

Carpel (Gr. *καρπός*, *fruit*). A name contrived by modern botanists to denote the separate pistils out of which a fruit, consisting of more pistils than one, is composed. In its most simple state a fruit consists of a one-celled ovary, and a style and stigma, united into a pistil, as in the plum; but in most cases several such pistils are formed within the same flower, and are united in various ways into one compound body, to which the name of pistil is also applied. In the latter case the single pistils are called carpels. The pistil may nevertheless consist of one carpel only. The theory of the structure of the fruit of plants turns upon the relative position which carpels bear to each other in their united state; and upon their correspondence in this respect with leaves, of which they are undoubtedly modifications.

Carpenter (Fr. *charpentier*, Lat. *carpentarius*, a *wheelwright*, from *carpentum*, a *car*). The workman who practises the art of shaping and framing timber used in the construction of buildings, such as piles, sleepers, posts, girders, joists, partitions, roofs, battening, and the application of the necessary ironwork. The other part of the timberwork in a building comes within the province of the JOINER [which see].

Carpenter in a ship's company is the third warrant officer on board a man-of-war, and he has charge of the boats; it is his duty, in conjunction with his mates, to attend constantly to the state of the well in order that a leak may be immediately reported.

Carpentry. In Architecture and Building, Carpentry means the assemblage of pieces of timber connected by framing, or letting them into each other, as are the pieces composing a roof, floor, centre, &c. It is distinguished from Joinery by the fact that the pieces of timber are put together without the use of other edge tools than the axe, adze, saw, and chisel; whereas joinery requires the use of the plane; the

CARPET

distinction is, however, very artificial, as all wrought timber is planned. The leading conditions to be attended to in sound carpentry are: 1. The quality of the timber used; 2. The disposition of the pieces of timber, so that each may be in such direction, considered with reference to the fibres of the wood, as to be most capable of performing its office properly; 3. The forms and dimensions of the pieces of timber employed; and 4. The manner of framing the pieces into each other, or otherwise uniting them by means of iron or some other metal. Nicholson divides the art of carpentry into *mechanical*, which treats of the nature and properties of woods, and the strains to which they may be submitted by their arrangement and disposition; *descriptive*, which consists in discovering the forms to be given to the different kinds or descriptions of timber; and *constructive*, which treats of the various practical methods of reducing the timbers and joining them where required. The best treatises on Carpentry are those of Nicholson, Robisson in his *System of Mechanical Philosophy*, Tredgold by Barlow; Kraft; and Emy, *Traité de la Charpenterie*, &c. &c.

Carpet (Ital. *carpetto*). An ornamental covering for the floor. The manufacture of carpets is carried on in great perfection in this country. The principal varieties are the Brussels, Axminster, Wilton, Kidderminster, and Venetian. They are generally composed of linen and worsted. In some the pile is cut so as to give the carpet the character of velvet, as in the Wilton carpets. Kidderminster or Scotch carpets are entirely fabricated of wool.

Carpet Way. Any strip or border of green sward left round the margin of a ploughed field.

Carpholite (Gr. *καρπος*, a dry stalk, and *λιθος*, stone). A hydrated silicate of alumina, manganese, and iron, found at Schlackenwald in Bohemia. It occurs in tufts of minute rhombic prisms, of a straw-yellow colour also massive, radiated, and earthy.

Carphosiderite (Gr. *καρπος*, and *σιδηρος*, iron). A very rare straw-coloured mineral with a resinous lustre and a greasy feel, found in kidney-form masses and incrustations in the mica-slate of Labrador and Greenland. It has recently been analysed by F. Pisani, who pronounces it to be a hydrated sulphate of peroxide of iron.

Carphostilbite (Gr. *καρπος*, and *Stilbite*). A straw-yellow and columnar variety of Thomsonite, from Beruford in Iceland.

Carpebalsamum (Gr. *καρποβαλσαμον*). The exudation of the fruit of the *Balsamodendron gileadensis*, a variety of balm of Gilead.

Carpolites (Gr. *καρπός*, fruit, and *λίθος*, a stone). Fossil fruits and seeds.

Carpology (Gr. *καρπός*, a fruit, and *λόγος*, discourse). That part of Botany which treats of the structure of fruits and seeds.

Carpophorum (Gr. *καρποφόρος*, fruitful). The name of the central column, which, in the fruit of the *Geranium*, the *Euphorbia*, or *Apia-coccus* plants, bears the ripe carpels, and holds

CARTE BLANCHE

them together when they attempt to separate at maturity.

Carpus (Lat.). In Anatomy, the segment of the skeleton of the upper or fore limb, answering to the wrist: it consists of eight small bones in the human subject.

Carragena. The vegetable jelly contained in Irish moss.

Carrel or **Quarrel** (Fr. *carré*, square). The arrow used in crossbows, the head of which was originally four-sided; a cross-bow bolt. Quarrels were the earliest projectiles fired from cannon.

Carrollite. A sulphide of copper and cobalt, of a tin-white colour inclining to steel-grey, occurring in a vein of Copper Pyrites at Finksburg, in Maryland, North America. It has a metallic lustre, and is named after the county (*Carroll county*) in which it is found.

Carronade. A short iron gun, which is attached to its carriage by a loop and bolt underneath the piece, instead of trunnions. It has less thickness of metal than other guns of the same calibre, and an enlargement or cup at the muzzle. As it admits only of a small charge of powder, its range is very confined: hence ships armed only with carronades have been beaten by vessels of nominally smaller armaments, composed of long-range guns. Carronades have thus become nearly obsolete. They were first introduced in 1779, by the director of the Carron foundry in Scotland.

Carrot (Fr. *carotte*). An esculent used both as a vegetable and for the purpose of cattle feeding. The cultivated carrots are improved succulent varieties of *Daucus Carota*.

Cart (A.-Sax.). An open box, placed upon two wheels, and constructed with shafts, so as to admit of being drawn by one or more horses. In agriculture, carts are used for carting or carrying from one point to another soils, manures, and produce. For this purpose there are the close cart, single or double, that is, for one or for two horses; the corn cart, single or double, constructed of open work, and used for carrying hay, and for conveying corn in the sheaf from the field to the rickyard, &c.; and the stone or quarry cart, consisting of a strong bottom and low wheels, for conveying large stones. Besides these, there are the three-wheeled cart, with low wheels, for carting soil, stones, &c. to a short distance; the timber cart, which is nothing more than two pairs of wheels and axles joined by a pole, and used for conveying large trunks of trees from the place where they have been felled to the place where they are to be manufactured; and the box cart, or cart with close bottom and sides, which is used for conveying soils, manure, and small articles, commonly constructed so as to admit of discharging the load by elevating one end of the box and lowering the other. To carts having this contrivance the term *coup cart* is applied in Scotland, and tilt cart in England.

Carte Blanche (Fr. *white paper*). A paper containing nothing but the signature of

the person who grants it, in order that the person to whom it has been delivered may insert such conditions as he chooses. This term is used in a general sense to express an unlimited authority delegated by anyone to another.

Cartel (Fr. ; Ital. *cartella, pasteboard*, from Lat. *charta, paper*). In Military language, an agreement for the exchange of prisoners. Also, a challenge to fight a duel. A cartel ship is one commissioned, in time of war, to carry proposals of any kind between belligerent Powers.

Cartesian Coordinates. [COORDINATES.]

Cartesian Ovals. Certain curves of the fourth order and sixth class, whose properties were first investigated by Descartes. (*Œuvres de Descartes*, vol. v.) A Cartesian oval may be defined as the locus of the four intersections of those diameters of two given circles which pass through the points in which the circles are cut, by a secant through a fixed point in the line joining their centres. An equivalent, but more convenient definition, however, is the locus of a point; fixed multiples of whose distances from two fixed points (the centres of the above circles) give a constant algebraical sum. Hence if r_1 and r_2 be the variable distances, A and B the fixed points, m_1 and m_2 the invariable multiples, and d the constant sum, the equation of the curve may be thus written:

$$m_1 r_1 + m_2 r_2 = d.$$

This equation, expressed in rectangular coordinates and cleared of radicals, may be made to take the form $S^2 = k^2 L$, where $S = 0$ represents a circle, k a linear constant, and $L = 0$ a right line; whence it may be seen that the curve has two cusps at the circular points at infinity, a property which distinguishes the curve from all others of the same order, and a double tangent L , whose points of contact coincide with its intersection points with S . The curve has also in general eight points of inflexion, but no double point.

The first of the above equations shows at once that the conic sections are included in the family of Cartesian ovals; in fact the ellipse corresponds to the case of $m_1 = m_2$, the hyperbola to $m_1 = -m_2$, the given points A and B being in each case the foci. In the general case, the number of foci being always equal to that of the class [FOCUS], three foci coincide with the centre of the circle S , and two with the points A and B; the sixth C is also in the line containing the others, and has precisely the same properties as A and B, so that the equation of the same oval might also be written in the form

$$\mu_1 r_1 + \mu_2 r_2 = c^2,$$

or, by elimination, in the form

$$\lambda_1 r_1 + \lambda_2 r_2 + \lambda_3 r_3 = 0.$$

Taking A as pole and AB as axis, the polar equation is obviously of the form:

$$r^2 + (a + b \cos \theta) r + c^2 = 0,$$

where a, b, c can be easily expressed in terms of m_1, m_2, d . The product of the two roots of this equation being constant ($= -c^2$), it follows

that a Cartesian oval is its own inverse with respect to either of its three foci. Lastly, it is evident that Cartesian ovals include the *Limaçon* of Pascal ($c = 0$), and hence also the *Cardioid* ($a = b, c = 0$).

Recent investigations on Cartesian ovals have been made by Charles, *Aperçu Historique*; Quetelet, *Nouveaux Mémoires de Bruxelles*, t. v.; Cayley, *Liouville's Journal*, t. xv. &c.; Salmon, *Higher Plane Curves*.

Cartesian Philosophy. The philosophical system of René Descartes (born 1596), a native of France, perhaps the most original thinker that country has produced. Descartes was the contemporary of Bacon, and exercised an equally powerful influence, though in a manner widely different, on the progress of philosophy in Europe. Both equally undertook the task of demolishing the old scholastic system, and of substituting in its place a more comprehensive method and a more living spirit. But what Bacon strove to accomplish by calling men's attention to experiment and observation of nature, Descartes proposed to attain by the search for a first and self-evident ground of all knowledge. This he finds in the act of consciousness, involving necessarily the idea of self or mind. (*Cogito, ergo sum.*) Consciousness is the act of thought, constitutes the essence of the soul, and is that which distinguishes it from matter. The ideas or objects of consciousness are of three kinds—acquired, compounded, and innate. Of the last sort is the idea of God, or the Absolute Being, which, as being the ground of all reality, is itself its own demonstration. God, the Author of the universe, upholds it in its course by His perpetual cooperation, or, in Cartesian language, assistance. All physical phenomena Descartes endeavoured to account for by his celebrated *vortices*—motions excited by God, the source of all motion. The singular mixture of philosophical depth and extravagant hypothesis that prevails in the writings of this philosopher obtained for him, as might have been expected, a large number of warm adherents, and of equally violent opponents. Among the former may be enumerated the celebrated Pascal, Malebranche, and Spinoza. The two latter deviated indeed in many important points from the views of Descartes; but the main features of his philosophy are preserved alike in the religious mysticism of the one and the systematic pantheism of the other.

Carthamine. The colouring matter of the *safflower*.

Carthamus. A genus of Composite plants, whose flower-heads are surrounded by numerous leafy buds in several rows, the outermost being broad and spreading with spiny edges, the middle ones erect, surmounted by an ovate appendage with spiny edges, and the innermost narrow entire and sharp pointed. The achenes have no pappus. *C. tinctorius* is the Safflower or Bastard Saffron, whose florets are extensively used for dyeing purposes, chiefly for silks. They are also used to adulterate saffron. [SAFFLOWER.]

CARTHUSIANS

In Ecclesiastical History, a religious order, instituted by St. Bruno in 1086; so called from their original seat, Chartreuse, near Grenoble in Vienna. They followed the rule of the *Benedictina Monach* [which see], of which it was in fact a reform, adding greatly to its austerities. Soon after their institution the Carthusians were introduced into England, where in the lapse of time they succeeded in establishing nine houses of their order, among which was the Charter-house in London. (*Histoire des Ordres Monastiques*, vol. vii.)

Cartilage (Lat. *cartilago*). A white elastic substance, intermediate between bone and ligament, and having the chemical properties of condensed albumen. It is commonly called *gristle*.

Cartilagineous. A sub-class of fishes, in which the endo-skeleton never passes beyond the primitive condition of gristle or carti [*CHONDROPTERYGII*.]

Cartoon (Ital. *cartone*, *pasteboard* or *large paper*). In Painting, a sketch or drawing made as a pattern for fresco or tapestry. The name is given to the large sketches on coarse or other paper for fresco subjects; in which case, when the stucco is setting, the outlines are pricked through on to it so that a correct outline may be expeditiously obtained.

The Cartoons is a term especially applied to the seven celebrated compositions of Raphael, now preserved at Hampton Court. They were originally ten in number, and were made for Leo X. in 1515 and 1516 as patterns for tapestries which were hung on the lower parts of the walls of the Presbyterium in the Sistine chapel at Rome during church festivals. Raphael received about 15*l.* each for the cartoons; while the tapestries made from them at Arras cost 7,000*l.* They are still preserved at the Vatican, but are no longer used for church purposes. The series of designs illustrated the lives of the Apostles, five of them referring to St. Paul alone. The seven at Hampton Court were bought by Charles I. by the advice of Rubens, and some sets of tapestry were afterwards worked from them under the direction of Francis Cleyné at Mortlake for James II. They represent: The Miraculous Draught of Fishes, or the Calling of Peter; Christ's Charge to Peter; the Healing of the Lame Man at the Beautiful Gate of the Temple; The Death of Ananias; Elymas the Sorcerer struck blind; Paul and Barnabas at Lystra; and Paul preaching at Athens. They were preserved to the nation by Cromwell, who purchased them at the sale of King Charles's effects for 300*l.* They have been engraved by Dorigny, Fittler, Holloway, and John Burnet. Some of the original tapestries made after the cartoons are preserved at Ford Abbey in Somersetshire. (*Wornum's Epochs of Painting*, ch. xviii. 1864.)

Cartouch (Fr. *cartouche*: Ital. *cartoccio*). In Architecture, the same as *MODILLION* [which see], except that this term is used almost exclusively to signify the blocks or modillions applied at the eaves of a house. Some have

CARYOCAR

used the term to denote the ornament of the key-stone of an arch, which seems to represent a scroll of paper partly unrolled.

Cartouche (Fr.). A case of leather or canvas for holding cartridges.

Cartridge. The exact charge of a musket, rifle, or fowling-piece, including both powder and bullet, or shot for sporting purposes, made up in a case, ready for loading. [*SMALL-ARM AMMUNITION*.]

Caruncate. [*PLOUGHLAND*.]

Carum. A genus of Umbellifera, one species of which, *C. Carui*, a biennial with finely cut leaves and compound umbels of white flowers, bears the caraway seeds used for flavouring purposes.

Caruncle (Lat. *caruncula*). A naked soft fleshy excrescence, often ornamenting some parts of the head of birds; as e.g. the caruncle on the cere of the king vulture (*Vultur papa*, Linn.).

Caruncula (Lat.). A small protuberance found near the hilum upon the seed of *Euphorbia Lathyris* and other plants.

Carvone. *Carum*. A hydrocarbon derived from oil of caraway by distillation with caustic potash.

Carya (Gr. *καρυα*, a nut). The genus of plants which includes the Hickory Nut of North America; a tree of the greatest value, for its tough elastic wood, as well as for the nuts, which resemble walnuts, except that their shell is not furrowed, and which are both eaten and pressed for their oil in their native country. There are several species of *Carya*: but *C. alba*, the White Hickory, a hardy ornamental tree in this country, is the most valuable.

Caryatides (Gr. *καρυατίδες*). In Architecture, this term is used to signify the figures

which are sometimes introduced to support a cornice instead of columns. According to the mythical account given by Vitruvius, they were so called to commemorate the disgrace of the people of Carya, a city in Arcadia, which was attacked and taken by the confederate Greeks for joining the

Persians, the men being killed and the women led into captivity. The fig. No. 1 is that of a caryatid from the Pandroseum, at Athens; No. 2 is a *ΚΑΡΥΑΤΙΣ* [which see]. When the figures introduced to support a cornice are male, they are said to be Persians; this is purely a modern name founded upon the tale related by Vitruvius, and adopted by the architects of the Renaissance.

Caryoccar (Gr. *καρυα*, a hard-shelled fruit). A genus of trees inhabiting the forests of tropical America, especially Guiana: one of them, found in woods near Mariquita, is said to attain the height of 240 feet. The *Saouari* (vulgarly called *Suwarrow*) or *Butternuts* of the shops, a delicious fruit, with a large

CARYOPHYLLACEÆ

soft buttery kernel, are the seeds of *Caryococcus* and other species. Properly the name Saouri applies to *Caryocar butyrospermum*.

Caryophyllaceæ (Caryophyllus, the Clove Carnation, a prominent plant of the order). An extensive natural order of Exogenous plants of the Silenal alliance, distinguished by their opposite leaves without stipules, symmetrical flowers, conspicuous corolla, and amphitropal ovules. One group, the *Aisinea*, consists of rather weedy plants, as *Arenaria* and *Stellaria*. While another, the *Sileneæ*, consists of the more showy *Dianthus*, *Silene*, *Agrostemma*, *Lychnis*, &c. The species do not possess any very important properties.

Caryophyllaceous. A corolla whose petals have long claws dilating into a broad limb, as in the Clove Carnation (*Dianthus Caryophyllus*).

Caryophyllia. [MADREPORE.]

Caryophyllic Acid. *Eugenio acid*. A colourless oily liquid forming the oxidised portion of the essential oils of cloves, pimento and cinnamon leaf.

Caryophylline. A crystalline substance (called also *Clove camphor*) deposited by a strong alcoholic tincture of *Cloves*. In composition it resembles common camphor: $C_{10}H_{16}O$.

Caryophyllus (Gr. *καρυφύλλον*, the clove-tree). The genus of *Myrtaceæ*, which yields the Cloves of commerce. These are produced by *C. aromaticus*, a tree of some twenty to thirty feet high, with large elliptic leaves and corymbs of purplish flowers having a long cylindrical calyx, four petals adhering by the points, and numerous stamens in four parcels. The cloves are the flower buds while yet unopened. They were formerly only grown in Amboyna, but are now cultivated in the West Indies and elsewhere.

Caryopsis (made up from Gr. *καρπov*, a nut, and *εψis*, appearance). The technical name of the grain of corn. It is an indehiscent one-celled fruit, with a membranous pericarp adhering firmly to the seed.

Caryota (Gr. *καρυώτις*). A genus of beautiful palms of lofty stature, wild in India and the Indian islands. *C. urens* grows to fifty or sixty feet in height, and has twice pinnated leaves, the leaflets of which are shaped somewhat like a scalene triangle with one margin deeply jagged. It yields amongst other useful products a large quantity of jaggery or palm sugar. Sago is also obtained from the pithy part of its trunk. A strong fibre called kital is extracted from the leaf stalks.

Caseable. That part of a piece of ordnance which lies behind the base ring. [GUN.]

Casculho. An indurated soil of Brazil forming the matrix of gold and of diamond in that country. It seems to consist of the fragments of those veins that have been by some means broken up, rolled by water, and buried among clays. The embedded stones are rough and angular, and thus the whole is a gravel formed on the spot and not exposed for any long period to the action of water. *Casculho* differs from

CASEINE

ordinary auriferous gravel, the latter being evidently waterworn and removed far from its source, whereas the former must be very near the parent rock judging from the condition of the stones.

The cascalho has not ceased to be important in reference to gold production in spite of the much larger supplies recently obtained from California, Australia, and other gold districts. It is still worked largely and to profit.

Some auriferous breccias in other countries have sometimes been called by this name, but without much real resemblance.

Cascarilla (Span. dim. of cascara, bark). The bark of the *Ocotea Eleutheria*, imported for medical use from Jamaica and the Bahama Islands. It is bitter and aromatic, and when burnt it diffuses an odour much resembling that of musk.

Cascarilline. The bitter principle of Cascarilla bark. It occurs in acicular crystals.

Case (Lat. casus; from cado, *I fall*). In Grammar, that modification of a noun which designates the relation in which a substance is conceived to exist in regard to some other substance. This end is commonly attained in language by changes in the termination of nouns. In English there are but three cases; the nominative, the genitive or possessive, and the accusative or objective case; the last only in pronouns. All other varieties of relation are expressed by prepositions. [GRAMMAR.]

CASE (Fr. casse). In Printing, the receptacle for the types, from which the compositor gathers them separately, and arranges them in lines and pages. They are usually in pairs; one of which is styled the upper case, and is divided into ninety-eight boxes or recesses of equal size, in which are deposited the capitals, small capitals, accented letters, figures, &c.; the other is called the lower case, and is divided into fifty-three boxes or recesses of unequal size, containing the small letters, spaces, &c.; the letters most in use having the largest boxes assigned to them. The cases are two feet nine inches long, one foot four inches and a half broad, and an inch in depth.

Case Hardening. The superficial conversion of iron into steel.

Case, Trespass on the. In Law, a form of action applying in cases of mediate or consequential injury. The distinctions between this and the common form of trespass for immediate injuries, formerly very difficult and refined, have been rendered unimportant by modern improvements. [PLEADING.]

Case-shot or Canister-shot. Consist of number of iron balls placed in a tin cylinder with a wooden bottom of the size of the piece of ordnance it is intended for. They are used only at short ranges, not exceeding 300 yards.

Caseic Acid. A peculiar acid extracted from cheese.

Caseine. The chief nitrogenous constituent of milk. It forms the greater part of cheese. It differs from fibrine and albumen in being coagulated neither spontaneously nor by heat,

CASEMATE

but by acids. Rennet, the substance produced by the slow decomposition of the rennet bag or fourth stomach of the calf, also causes the coagulation of casein, as seen in the curdling of milk.

Casemate (Fr.). In Fortification, a bomb-proof arched chamber, usually constructed under the ramparts. It serves for a battery, and for cover for the men off duty, the sick and wounded, &c.

Casement. In Architecture, this word is applied to a vertical sash hung upon hinges. It is also used in the sense of the moulding called a SCOTIA.

Caserns (Fr. caserne). Huts erected on the ramparts, or between the ramparts and the houses, of fortified towns, serving as temporary lodgings for the soldiers on duty.

Casium (Lat.). The basis of cheese. The peculiar curd of milk.

Cash (from Fr. caisse, a box). In Commerce, the ready money, bills, drafts, bonds, and all immediately negotiable paper in an individual's possession.

Cashew Nut. The fruit of the West Indian *Anacardium occidentale*.

Casket. A small rope used to fasten the sail to the rope in furling. [GASKET.]

Caspian Sea. [ARALO-CASPIAN.]

Cassamunar. An East Indian root, formerly used in medicine as a warm bitter.

Cassandra. [PARIS.]

Cassareep. The inspissated antiseptic juice of the Cassava, which forms the basis of the West Indian pepper-pot.

Cassation, Court of. The highest judicial institution in France; so termed from possessing the power to quash (casser) the decrees of inferior courts. It is a court of appeal in criminal as well as civil cases. The tribunal of cassation was first introduced, as a court wholly independent of the king and his council, in 1790. This court is under a president; but the minister of justice, as keeper of the seals (*garde des sceaux*), has the right of presiding in cases where it sits on appeal from the *cours royales*. The three sections are: 1. Des requêtes, which decides on the admissibility of petitions of appeal in civil cases; 2. De cassation civile; 3. De cassation criminelle. The decision of the court of cassation has the effect of sending back the case to the inferior courts. If, after a decision has been reversed, a second court decides the same case in the same way, and on appeal being entered again, the court of cassation repeats its reversal by all the three sections, such judgment is final. The inferior judges of the three sections of the court of cassation are styled *counsellors*.

Cassava. The purified starch obtained from the roots of the *Manihot utilisima*.

Cassell Yellow. A compound of oxide and chloride of lead: it is also known in commerce under the name of *patent yellow* and *Turner's yellow*.

Cassia (Gr. *kasla*). A genus of Leguminous plants of considerable importance from a medical

CASSINIAN OVALS

point of view, inasmuch as it is the source of Senna leaves. Alexandrian senna is made up of *C. acutifolia* and *C. obovata*, East Indian or Tinnevely senna of *C. elongata*, and Aleppo senna of *C. obovata*. They are annual and somewhat shrubby herbaceous plants, with compound pinnated leaves, and flowers having five unequal sepals, five yellow not papilionaceous petals, and ten stamens, of which three are long, four short, and three sterile or abortive. They differ in the form of their leaflets: those of *C. obovata* being obovate; those of *C. acutifolia* and *elongata*, lance-shaped. Other species, but probably of less importance than these, are grown. *C. fistula* is sometimes called CATHARTOCARPUS.

CASSIA or CINNAMON. The bark of the *Laurus Cassia*; its flavour somewhat resembles that of cinnamon, and it yields an essential oil, which is pungent and stimulant.

Cassideous (Lat. *cassia, a helmet*). In Botany, when the upper petal of a flower is dilated into a broad helmet-shaped leaf, as in the genus *Aconitum*.

Cassididae (Lat. *cassia, a helmet*). A family of Tetramerous Coleoptera, generally known by the name of tortoise-beetles, distinguished by having straight short filiform antennae, inserted close together in the upper surface of the head, mouth situated on the under surface of the head, with strong and broad mandibles; legs short, with the tarsi flattened, the third joint deeply cleft, receiving between its lobes the terminal joint; margins of the thorax and elytra much dilated, so as to give the insects the appearance of small tortoises. The larva of the *Cassididae* is remarkable for an apparatus, or anal fork, by which it collects and forms of its excrements a kind of parachute or defensive covering.

The genera of *Cassididae* are, *Alurnus*, *Hispa*, *Chalepus*, *Imatidium*, and *Cassida*; the latter is the only indigenous genus, and of this the most common example is the *Cassida aquestris* of Fabricius.

Cassinian Ovals. Such an oval may be defined as the locus of the vertex of a triangle of which the base and rectangle under the sides are given. Taking the base (2a) as axis and its middle point as pole, the equation is clearly $r^4 - 2a^2r^2 \cos 2\theta + a^4(a^2 - b^2) = 0$, where a b is equal to the constant rectangle.

In rectangular coordinates the equation is $(x^2 + y^2)^2 + 2a^2(x^2 + y^2) - 4a^2x^2 + a^4(a^2 - b^2) = 0$, whence it is concluded that the ovals in question are curves of the fourth order and eighth class. The circular points at infinity are double points, the tangents at which meet the curve in four consecutive points, that is to say each branch of the curve has also an inflexion at these points. The extremities of the base of the triangle are foci of the curve. As b increases from zero, the curve, starting from the initial state of two isolated points, becomes transformed into a pair of ovals around those points, until the value $b = a$ is reached, when the two ovals join and form the *lemniscata* of Bernoulli.

CASSIOPEIA

After this the curve consists of one continuous oval surrounding all the preceding ones.

Cassiopeia (Gr.). One of the constellations of the northern hemisphere.

Cassals (Lat.). A genus of Gastropodous Molluscs, separated by Lamarck from the Linnean genus *Buccinum*, and including the species of which the shells are commonly called 'helmets.' The nacreous or inner layers of these shells are exquisitely sculptured by Italian artists in imitation of antique cameos the different coloured layers of the shell resembling the onyx and other precious stones.

Cassiterite (Gr. *κασσίτερος*, tin). Native peroxide of tin; composed, when pure, of 21.62 per cent. of oxygen and 78.38 tin. It occurs massive (*Tin-stone*), disseminated, fibrous (*Wood-tin*), in rolled pieces and in grains as sand (*Stream-tin*), and crystallised in quadrangular prisms terminated by four-sided pyramids and in many complex forms: sometimes in twin crystals. The colour is of all shades between light brown and black, but it sometimes has a greenish tint, and is sometimes colourless, as at Mount's Bay in Cornwall, where transparent, white, glassy crystals of great beauty (*Tin-diamonds*) have been met with. The darker crystals are in general opaque, and the lighter ones translucent and semi-transparent. Lustre splendid.

The peroxide is the common ore of tin, and the only one from which the metal is obtained. It occurs in veins and large irregular masses, disseminated in granite, gneiss, clay-slate, mica-slate, and porphyry. The largest supplies are obtained from Cornwall, where mines have been worked for tin from a very remote antiquity. The principal Cornish mines are in the neighbourhood of St. Agnes, St. Ives, Gwennap, Helstone, and Penzance in the west, and near St. Austell in the east; small quantities are also procured near Tavistock. The other chief localities are the island of Banca, off the north-east coast of Sumatra; the peninsula of Malacca; Finland, Sweden, Greenland, France, Spain, Bohemia, Saxony, Chili, Peru, Mexico, California, and Australia under the form of black sand, in the alluvial gold washings.

Cassiterotantalite. A variety of Tantalite, from Finbo and Proddbo in Sweden, containing a large amount of oxide of tin mechanically mixed with it.

Cassius, Purple of. So called from its inventor. A beautiful purple used in porcelain painting, and for staining glass. It is formed by immersing tin in a solution of gold. It is probably a mixture of oxide of tin and finely divided gold.

Cassowary (*Casuarus*, from the Malay word *cassuwaris*). A genus of Coursers or Struthious birds, inhabiting the islands in the Indian archipelago; the wings are shorter than in the ostrich, and are armed with strong spines, for the purpose of combat or defence. The head is surmounted by a bony protuberance covered with horn.

CASTE

Cassythaceæ (*Cassytha*, the only genus). A most singular natural order of plants, having the fructification of the *Lauraceæ*, and the manner of growth and general appearance of a *Rhipsalis*, or rather a *Cuscuta*. They inhabit the tropical parts of the world, and are now regarded as an anomalous group of *Lauraceæ*.

Cast Iron. [IRON.]

Cast, Rough. [ROUGH CAST.]

Castanea (Lat.). A genus of trees or shrubs, related to the oak, and producing for fruit the seed-like nuts called Chestnuts in this country. The common Spanish Chestnuts, of which large quantities are annually imported from the south of Europe, are the fruit of *C. vesca*. A much smaller nut is obtained in North America from the *C. pumila*, or the Chinquapin Chestnut. The timber of the common Spanish chestnut is good and durable, more so than that of the oak, when the latter is young; but the notion that the ancient roofs and beams occasionally found in buildings of the Norman era, and which carpenters call chestnut, are the wood of this tree, appears to be erroneous. Such instances all belong to the kind of oak called *Quercus sessiliflora*. The genus *Castanea* differs from *Quercus*, among other things, in having the nuts enclosed in a spiny closed-up cup, instead of a shallow open one; but in the East Indies, where both oaks and chestnuts assume very remarkable forms, the two approach each other sometimes so nearly in this particular, that it is difficult to distinguish them.

Castanets (Span. *castañeta*, Fr. *castagnettes*). Small wooden or ivory musical instruments, played by being tied to the fingers, and thus rattled by dancers to the time of the music of the dance. They are chiefly used in Spain.

Caste (Port. *casta*). A term borrowed from the Portuguese settlers in India, which is used to denote the hereditary classes into which the population of Hindustan is divided, according to the religious law of Brahma. The origin of these classes is detailed in the sacred book which contains the ordinances of Menu. According to this authority, the Brahman, the Kshatriya, the Vaisya, and the Sudra sprang respectively from the mouth, the arm, the thigh, and the foot of Brahma. 1. The class of Brahmans, or priests, are far exalted above the rest in honour and privilege, and should be devoted entirely to prayer and meditation, or at least to the most exalted concerns of life. Many Brahmans, however, do in fact engage in secular pursuits, not only as ministers of sovereign princes (an office for which, according to the ordinances above cited, they are indeed peculiarly fitted), but also, in Guzerat and other parts of Western India, as merchants, or in the lower employment of messengers and porters; while many enter the British service as private soldiers. These, however, are Brahmans of the first and second classes (*Brachmachari* and *Grihast'ha*), youths or married men who as yet live in the world; from which the two higher classes, *Vanaprastha* and *Sunnyassi*, are wholly divorced. From the latter spring the various orders

of fanatics with which India swarms. 2. To the Kahatriya, or soldier caste, belong not only the high military classes, but in some parts of India whole tribes, as the Sikhs, &c. 3. The Vaisya, or commercial class (*wealth*). 4. The Sudra, or caste of tillers of the soil (*labour*). These are deeply degraded below not only the Brahmans, but the other two castes; and even the reading of the Vedas or sacred books is forbidden to them. Besides these four grand divisions, the Hindus have many subdivisions of caste, and no fewer than thirty-six are reckoned which are all inferior to the Sudra. These descend, according to the mythological history of the Hindus, from the 'Burren Sunker' or mixed class, proceeding from the confusion of castes which took place under the reign of a wicked and irreligious monarch. Finally, the Pariahs and some other races are considered as having no caste at all, and mere outcasts from humanity. Traces of the system of caste, which confines employments to hereditary classes, are to be found in the institutions of many countries, and in the history of many more. That the Egyptian nation was thus divided, is well known; and it is supposed that similar institutions prevailed in the ancient Assyrian empires. If Plato can be relied on as an authority, the Athenians in the first ages of their commonwealth were divided into five classes of the same description — priests, handicraftsmen, shepherds and hunters, ploughmen, soldiers. The Cretans, it is said, were divided, according to the laws of Mino, in the same manner as the Egyptians.

Castellated (Lat. *castellum*, a fortress). In Architectural works, the term castellated is applied to buildings finished in the style of a castle or of military architecture.

Castellite. The name given by Breithaupt to crystals of a clear yellow colour, which are found with brownish yellow Spheer, in phonolite, at Saalesel in Bohemia.

Castelnaudite. A variety of Xenotime found in imperfect crystals and irregular grains of a greyish white to a pale yellow colour, in the diamond-sands of Bahia in Brasil. It consists chiefly of hydrated phosphate of yttria.

CASTING. A term used in Architecture to express the bending of the surfaces of a piece of wood from their natural state, caused either by the gravity of the material, or by its being subject to unequal temperature, or by the inequalities of texture of the material. It is more commonly called *Warping*.

CASTING. In Foundry, the running of liquid metal into a mould prepared for that purpose. [FOUNDREY.]

CASTING. In Seamanship, is the act of allowing the ship's head, previously pointing to the wind, to fall off so as to bring the wind on the vessel's side.

Casting off Copy. In Printing, ascertaining accurately how many pages in print a given quantity of manuscript copy will make; or how many pages a given quantity of printed copy will make when the size of the book and

the type are changed; also when a given quantity of manuscript copy is delivered, with directions that it is to make a certain number of pages in print, to determine the size of the page and the size of the type. This is usually done by composing a line or two of the copy, when, supposing a line and a half of it makes a line of print, it becomes a mere arithmetical question. Supposing there are 12,000 lines of copy, it will make 8,000 lines in print, which, at 24 lines to a page, will be 333 pages, and with the title, short pages &c. equal 14 sheets in 12mo.

Casting of Draperies. In Painting, the disposition of the folds of the garments wherewith the figures in a picture are clothed. Carlo Maratti thought that the disposition of drapery was a more difficult art than even that of drawing the human figure, and that a student might be more easily taught the latter than the former. Inferior painters enter into the minute discriminations of quality in drapery; but, as Sir Joshua Reynolds has well observed in his Fourth Discourse, with the historical painter 'the clothing is neither woollen nor linen, nor silk, satin, nor velvet; it is drapery; it is nothing more.' The figures of Raphael, in his painting, are generally draped; those of Michael Angelo commonly nude.

Castle (Lat. *castellum*). In Architecture, a building fortified for military defence, and also a house with towers, usually accompanied with walls and a moat, and having a donjon or keep in the centre. The principal castles in England at present are the Tower of London, Dover, Windsor, Norwich, &c.; but at one time those of Harwood, Spofford, Kenilworth, Warwick, Arundel, and others, might have vied with them in importance. The characteristics of a castle are its valls (embankments) and fosses (ditches), from the former of which the walls arise usually crowned by battlements, and flanked by circular, or polygonal, bastions at the angles formed in the walls. These walls were pierced for gates with fixed or draw bridges and towers on each side; the gates, which were of considerable strength, were further guarded by descending gratings called *portcullises*; and all the apertures were made as small as they could be consistently with the requirements of internal lighting. The component parts of a castle were: 1. The foss, or moat, with its bridge; 2. The barbican, which was in advance of the castle, and was a raised mound or tower, the outer walls having terraces towards the castle, with bastions, as above mentioned; 3. The gatehouse, flanked with towers and crowned with projections called machicolations, through which heavy materials or molten lead were dropped on the assailants entering the gateway; 4. The outer ballium or area within the castle, which was separated from the inner ballium by an embattled wall with a gatehouse, and where the stables and other offices usually stood; 5. The inner ballium for the residence of the owner or the governor with his retinue; this had at one corner, or in

CASTOR

the centre, a donjon, or keep, which was the stronghold of the place, and usually contained the state apartment; 6. A well, and a chapel; the former usually, and the latter frequently, are found in ancient castles which are complete in their arrangements.

For further information on the subject, the reader is referred to King's *Mun. Antig.* fol. 4 vols.; the *Archæologia*, in several places Leland's *Collect.* vol. xi.; Woolnoth's *Ancien. Castles of England and Wales*; and to Viollet le Duc, *Architectures Militaires du Moyen Age*.

Castor (Gr.). A remarkable double star in the constellation Gemini, called also a Geminorum. The two stars, which are easily separated by a moderately good telescope, rotate around their common centre of gravity, and, according to Sir J. Herschel, complete their rotation in a period of 253 years. (*Mem. Royal Astron. Soc.* vol. v.)

CASTOR. A peculiar concrete substance, contained in oval pouches situated near the anus of the *Castor Fiber* or beaver. There are four of these pouches; two contain a species of fat; while the two larger ones include in their membranous cells a viscid fetid substance, which is the *castor* of the *Materia Medica*. It is imported from Russia, Prussia, and Poland, and from Canada: the latter, known in trade under the name of *New England castor*, is very inferior. It is said to be an antispasmodic.

CASTOR. A silicate of alumina and lithia found in imperfect crystals in geodes embedded in the granite of Elba, with an allied mineral which has received the name of Pollux, and crystals of Felspar, Quartz, Beryl, Tourmaline, &c. It is colourless and transparent, and has a high glassy lustre.

CASTOR. The generic name of the beaver (*Castor Fiber*, Linn.).

Castor Oil. The expressed oil of the seed of the *Ricinus communis*, or *Palma Christi*. It is a mild aperient.

Castor and Pollux. The name given to an electrical meteor which, sometimes appears at sea, attached to the extremities of the masts of ships under the form of balls of fire. When one light only is seen, it is called Helena. The meteor is generally supposed to indicate the cessation of a storm or a future calm; but Helena, or one ball only, to portend bad weather. [POLYDORUS.]

Castrametation (Lat. *castrum*, a camp, and *metor*, I measure). The art of laying out camps, whether the troops to occupy them are to be hutted, under canvas, or bivouacked. The situation for a camp should be healthy, not liable to be flooded, well provided with water, and should have good supplies of forage and wood close at hand. If troops are on active service it must be capable of defence, and should not be overlooked. [CAMP.]

Casuarinaceæ (Casuarina, one of the genera). A curious natural order of plants, inhabiting New Holland, some parts of India, and the South Sea Islands, with long slender creeping branches, resembling those of *Equisetum*, and bearing only scales in the place of

CAT-O'-NINE-TAILS

leaves. The order is nearly allied to *Myricaceæ*, and belongs to the most imperfect forms of Exogenous vegetation, ranking in the Amœntal alliance, where they are known by their one-celled ovary and one or two ascending ovules, with a superior radicle. The *Casuarinas* are called Beefwood.

Casulist, Casuistry (from Lat. *casus*). In Theology, a casuist is a doctor charged with the decision of cases of conscience. The Jesuits were distinguished for the cultivation of this mixed subject of theology and ethics; which was admirably calculated to promote the policy of that order. The science of moral theology deals with the enunciation and exposition of principles; but casuistry, in the common acceptation of the term, confines itself to particular cases as they arise, and has led to narrow views and great perversions of truth and morality. The teaching of casuistry was common to Lutherans and Calvinists in the sixteenth century, as well as to Romanists; but it was by the Jesuits that it was chiefly cultivated, so that in common language Jesuitical and Casuistical have become almost equivalent terms of reproach. (Mayer's *Bibliotheca of Casuists*.)

Cat. A ship employed in the coal trade.

CAT. Tackle by which the anchor is raised to the cathead. (Falconer's *Dict.*)

CAT. [FALX or FELIX.]

Cat Head. A Nautical term, signifying a strong inclined piece of timber projecting from either bow of a ship, to which the ring of the bower anchor is secured. The block or pulley hooked to the ring is called the *cat-block*, the rope the *cat-fall*.

Cat Silver. A name given to Mica by the old German miners.

Cat's-eye. A beautiful variety of translucent chalcedonic Quartz, of various shades of greenish grey or brownish red. The substance of the stone is penetrated by small parallel fibres of Asbestos, and when polished it displays a peculiar pearly opalescence, or floating internal light [CHATYANT], much resembling the mutable reflections exhibited by the contracted pupil of the eye of a cat when held towards the light. It is chiefly brought to this country from Ceylon; but it also occurs in Scotland, and a pale-green variety is found in the Vale of Llanberis in Caernarvonshire, associated with Epidote. It is used in jewellery, and is cut *en cabochon*.

Cat's-tail Grass. A valuable meadow grass, usually forming part of all good low-land pastures. It is the *Phleum pratense*, a plant with a soft narrow cylindrical head, resembling that of the meadow Foxtail Grass.

Cat-barrings. Small ropes used to tighten the shrouds below the tops, and to draw them towards the mast that they may not interfere with the swing of the yards.

Cat-o'-nine-tails. A whip divided into nine strings of knots which forms a terrible instrument for the infliction of corporal punishment in the navy and army, and in certain cases in the civil prisons.

CATABAPTISTS

Catabaptists (a word formed on a false analogy from Gr. *κατά*, against, and *βαπτίζω*, I baptize). In Ecclesiastical History, a general term to designate all the sects which have denied the necessity of baptism generally, or have opposed infant baptism. [BAPTISTS; QUAKERS SOCIETARIANS, &c.]

Catopnetics (Gr. *κατά*, and *αἴαλος*, I burn). In Optics or Geometry, are the *caustic* curves formed by the reflection of the rays of light, and so called to distinguish them from the *diacustic*, which are formed by refracted rays. [CAUSTIC.]

Cataphoresis (Gr. *κατά* and *φέρω*). In Rhetoric, a figure by which a word is used in a sense analogous to its own. [METAPHOR.]

Cataphlestum (Gr. *κατά*, against, and *κλάω*, I enclose). A name applied sometimes to such a fruit as that of *Mirabilis*, which consists of a membranous indehiscent pericarp enclosed within a hard pericarp-like tube of the calyx.

Cataclysm (Gr. *κατακλυσμός*, an inundation, a deluge). Geologists apply the word to signify the various great inundations which they conceive to have occurred at different periods in the history of the globe.

Catacomb (a word of very doubtful origin; the Low Latin form is *catacumba*). In Architecture, the name given to passages excavated in the soil with recesses for graves, or for cells used as bone-houses. The hypogæa, crypta, and cometeria of the ancients were used for the same purpose. In some cities it would seem that the great excavations made for the catacombs were devoted to other purposes than the interment of the dead, as at Syracuse the same cavern served for a prison as well as for a cemetery; and at Rome it appears that the catacombs were resorted to for the purpose of worship. The most celebrated excavations for the purpose of cemeteries are those of Rome, Naples, Syracuse, &c.; and those formed by quarrying for the stone used in building the city of Paris.

Catopnetics or **Cataphonics** (Gr. *κατά*, and *αἰσώω*, I hear; *φωνέω*, I speak). The science of reflected sounds; or that part of acoustics which treats of the properties of echoes, or in general of sounds which do not come to the ear directly, but after having been reflected by some substance. [ECHO and SOUND.]

Catapultæ (Fr.). In Architecture, a temporary structure of Carpentry decorated with painting or sculpture, representing a tomb or cenotaph, and used in funeral ceremonies.

Catagrapha (Gr.). [FORESHORTENING.]

Catalectic (Gr. *καταλειπτός*, deficient). In Greek and Latin poetry, a verse wanting one syllable of its proper length: *acatalectic*, a verse complete in length; *hypercatalectic*, having one syllable too many; *brachycatalectic*, wanting two syllables.

Catalecticness. A certain invariant which, together with the canoniant, presents itself in the problem of the reduction of a quantic to its canonical form. The vanishing of the cata-

CATAMENIA

lecticant, in fact, indicates the possibility of expressing a binary quantic of an even degree ($2n$) in the form of a sum of half this number of $2n^{\text{th}}$ powers. For instance, the catalecticant of the binary quantic $(a, b, c, d, e \sqrt{x}, y)^4$ is the determinant

and if this vanishes identically the quantic in question will be expressible in the form $u^2 + v^2$, where u and v are linear functions of x and y . In this particular case the catalecticant is the cubinvariant of the quartic. [INVARIANT.] In general the catalecticant of the quantic

$(a_0, a_1, \dots, a_n, x, y)^n$ is the symmetrical determinant of the $(n+1)^{\text{th}}$ order

$$\begin{vmatrix} a_0 & a_1 & \dots & a_n \\ a_1 & a_2 & \dots & a_{n+1} \\ \vdots & \vdots & \ddots & \vdots \\ a_n & a_{n+1} & \dots & a_{2n} \end{vmatrix}$$

whose formation is very simple. Mr. Sylvester's papers in the *Philosophical Magazine*, 1851, and *Cambridge and Dublin Math. Journal*, vol. vi., will furnish the reader with further details on the subject.

Cataplexy (Gr. *κατάπληξις*, an attack). A disease in which the functions of the organs of sense and motion are suspended, whilst the heart continues to pulsate. The patients are said to be in a *trance*; and in this state they remain sometimes for hours, or even days.

Catalogue Raisonné (Fr.). In Bibliography, a catalogue of books, classed under the heads of their several subjects, and with a general abstract of the contents of works where the title does not sufficiently indicate it; thus serving as a manual, to direct the reader to the sources of information on any particular topic. The want of alphabetical arrangement is supplied by an index at the end. The catalogue of the French *Bibliothèque Royale* (10 vols. fol. 1789—53) is said to be the best work of this description, as far as it extends. A very valuable one has been commenced, but as yet only partially executed, of the National Library at Paris. [BIBLIOGRAPHY.]

Catalysis (Gr. *κατάλυσις*, a dissolving). That process in which a substance excites by its mere presence (and without undergoing change itself) some chemical action in the substances with which it is in contact.

Catamaran. A sort of raft used chiefly by the Indians on the Coromandel coast for the purposes of fishing. It is composed of three pieces of wood lashed together, the middle piece being longer and broader than the others: and it is almost the only kind of boat that can live in the surf that prevails on that coast. The name Catamaran was also given to the floating batteries with which the French at the commencement of the present century meditated the invasion of England.

Catamenia (Gr.). The monthly uterine evacuation.

CATAPETALOUS

Catapetalous (Gr. *κατὰ*, against; *πέταλον*, a leaf). When the petals of a flower are held together by stamens which grow to their bases, as in the Mallow.

Cataphracted (Gr. *καταφρακτος*). Covered with a hard callous skin, or with horny or bony plates or scales closely joined together. Among the ancients, cavalry with complete defensive armour were termed *equites cataphracti*.

Cataphrygians. [MONTANISTS.]

Catapleite. A silicious mineral containing Zirconia of a pale yellowish brown colour, occurring in imperfect hexagonal crystals which are opaque, and nearly dull, in the island of Lano, near Brevig in Norway.

Catapult (Gr. *καταπέλτης*). A Military engine used by the ancients for throwing stones, long darts, or javelins. The catapult is often confounded with the balista; but the latter engine seems to have been chiefly used for the purpose of propelling stones, while the former more frequently was employed with other missiles. Their size and construction various, but the principle of action was the same in all; namely, the elastic force with which twisted rope uncoils itself.

Cataract (Gr. *καταρράκτης*). An of the crystalline lens of the eye, confused or indistinct vision, or total according to the less or greater extent of the thickening: it is sometimes rapid, and often very slow in its progress. It is distinguished from *gutta serena* by the visible opacity of the lens, and by the iris contracting upon exposure of the eye to light. This disease is curable either by depressing or extracting the lens, operations which are performed with wonderful dexterity by some modern oculists.

Catarrh (Gr. *καταρρής*, I flow down). The complaint commonly called a *cold in the head*, generally attended by running from the eyes and nose, sneezing, hoarseness, and commonly ending in cough. It is produced by sudden

remedies relieve it—diluenta, mild aperients, and abstinence from wine and animal food; but when attended by fever, headache, tightness about the forehead, and difficult breathing, it often requires more serious attention, and if neglected may lead to much mischief.

Catarrhines, **Catarrhina** (Gr. *κατάρρής*, with a curved nose). A tribe of Quadrumanes, including those which have the nostrils approximated, and the intervening septum narrow; as in the apes of the Old World.

Catastrophe (Gr. from *καταστρέφω*, I overturn). In modern Literary language, the final event of a drama or romance, to which the other events are subsidiary. The *περίεργεια*, or revolution, indicated by Aristotle as one of the parts of the drama, was a change in the fortunes of the principal personages of the play: as the fall of Œdipus from sovereignty into extreme misery and banishment, in the *Œdipus Tyrannus*. Some such change is generally involved in the idea of a catastrophe: thus,

CATEGORICAL PROPOSITION

marriage is the ordinary catastrophe of a comedy or a novel, as some disastrous change is that of a tragedy.

Catch-drains. Open drains across a declivity to intercept surface water. The term is sometimes also applied to under-drains across a declivity.

Catchword or **Direction-word**. In Printing, the first word of a page printed at the bottom right-hand corner of the preceding, to assist the reader. The first edition of Tacitus, printed at Venice by Johannes de Spira about 1469, is the earliest book in which catchwords are found.

Catchwork-meadows. Grass lands with a very regular sloping surface, subjected to irrigation, the water as it descends the declivities being intercepted by catch-drains.

(Gr. *κατηχημα*, I instruct by word of mouth). A form of instruction by question and answer, appropriated by general usage to instruction in religious subjects, and more especially to the set forms which most churches have authorised for the instruction of children in the elements of religion. The English church catechism is intended to be an exposition of the vow made at baptism, and till the time of James I. consisted only of the repetition of the baptismal vow, the creed, and the Lord's Prayer. The latter portion, explaining the nature of the sacraments, added after the conference at Hampton Court. The catechism of the council of Trent, or *Catechismus ad Parochos*, was set forth by the Roman Catholic divines for the use and direction of the clergy, and contains an ample account of the whole sum of the Romish doctrines. It was approved by Pius V., and published in 1566. (Bingham's *Antiquities*, b. x. ch. i. ii.)

(a Japanese word, signifying the juice of a tree). The extract of the *Acacia Catechu*, an astringent substance, consisting of tan and extractive matter, imported chiefly from Bengal and Bombay. Also the inspissated juice of the palm, *Areca Catechu*. Its principal use is in medicine.

Catecholic Acid. A substance in the form of white silky filaments contained in *Catechu*. Its formula is $C_{14}H_{10}O_8$. It has also been termed *Catechine* and *Tanningenic acid*.

Catechumen (Gr. *κατηχομενος*). He who learns the elements of any science: one who is undergoing a course of religious instruction with a view to his admission into the church. The Christian society in the early ages was divided into two classes, Fideles and Catechumeni: the former being those who had been admitted by baptism into the entire privileges of the church, the latter such as were preparing for that admission.

Categorematic (Gr. *κατηγορημα*, a predicate). In Logic, when a word is capable of being employed by itself as a term, or predicate of a proposition.

Categorical Proposition (Gr. *κατηγορημα*, I declare something of another). In Logic, a proposition which affirms or denies, absolutely

and without any condition, that the subject does or does not agree with the predicate. [PROPOSITION.] Categorical propositions are said to be pure (those which simply assert one thing of another), and modal (those which assert one thing of another under a certain mode or form). But this is a distinction arising out of the poverty of language only, and no essential difference between the two classes; e. g. 'the king reigns' is a pure categorical proposition; 'the king reigns justly' is said to be modal. But it is evident that if our language had a single word to express the whole idea (to reign justly), the latter would be called pure likewise. All cases of modal categoricals may probably be resolved into similar instances of the deficiency of words to express complicated notions.

Category (Gr. κατηγορία). In Logic and Metaphysics, a Greek word, signifying originally that which may be said or predicated of a thing; a general term in reference to a less general one which is included under it. By Aristotle, from whom the word, and its corresponding Latin term *predicate*, was borrowed by the schoolmen, it was applied to denote the *most general* of the attributes that may be assigned to a subject. Of these he attempted an enumeration, under the names of substance, quantity, quality, relation, place, time, condition, state or habitude, action, and passion. The word has been revived in modern times by Kant, to express the most general of the modes in which a thing can be raised from an object of sense to an object of intellect; or, in other words, the forms or conditions which must pre-exist in the understanding, in order that an act of intelligence may take place. For an account of these, see KANTIAN PHILOSOPHY. The difference between the categories of Kant and those of Aristotle is this, that the latter are mere generalisations from experience, which may consequently be multiplied indefinitely; whereas the former result from a professedly exhaustive analysis of the human understanding as it is in itself, or formally, that is, apart from all consideration of its object-matter.

Catenarian (Lat. catenarius, *belonging to a chain*). In Engineering, this term is applied to that form of arch which resembles the curvature a chain would assume if hung between the points of suspension, and reversed.

Catenary. The curve into which a chord or flexible chain of uniform density and thickness forms itself when suspended or allowed to hang freely from two fixed points, A, B. This curve was first noticed by Galileo, who proposed it as the proper figure for an arch of equilibrium; but he imagined it to be the same as the parabola. Its true nature was first demonstrated by James Bernoulli, and its various properties soon after pointed out by John Bernoulli, Huygens, and Leibnitz. It is interesting in its relation to the theory of arches, and also by reason of its application to the construction of suspension bridges.

The mechanical conditions of equilibrium, when expressed mathematically, lead to the

differential equation $s = h \frac{dy}{dx}$; where s (horizontal) and y (vertical) denote the coordinates of any point M on the curve, and s the arc CM measured from the lowest point C, whose coordinates are o and h respectively. The mechanical definition of h is important; the weight of this length of string is precisely equal to the tension of the cord at the point C, and it can

moreover be easily shown that the tension at any other point M of the catenary is similarly measured by the corresponding ordinate MP; so that, O being the origin of the coordinate axes, and the points C and M being fixed, if portions of the string equal to MP and CO were cut off from the arcs MA and CB and allowed to hang freely from M and C, the equilibrium of CM would not be disturbed. The integration of the above differential equation leads to the relation $y^2 = s^2 + h^2$, and thence to the equation

$$y = \frac{h}{2} \left(e^{\frac{x}{h}} + e^{-\frac{x}{h}} \right)$$

of the curve; e being the base 2.7182818 of the natural system of logarithms.

The first two of the preceding equations lead to other interesting constructions. Let MSP be a right-angled triangle having the ordinate $y = MP$ for hypotenuse and $PS = h = OC$ for one of its sides, the other side MS will obviously touch the curve at M, and be equal in length to the arc MC. The locus of S, therefore, will be the involute of the catenary, a curve known as the *Tractrix*, and belonging to the family of equi-tangential curves; the portion PS intercepted upon any tangent by the point of contact and a fixed line OX being constant. [TRACTRIX.]

For further information on the subject, see Poisson's *Mechanics*; Gregory's *Examples*; Wallace, *Edinburgh Transactions*, vol. xiv.; Whewell's *Analytical Statics*; Ware's *Tracts on Vaults and Bridges*, London 1822, &c.

Catenulate (Lat. catena, *a chain*). When a surface presents a series of elevated ridges or oblong tubercles resembling a chain.

Caterpillar. The name of the larvæ of Lepidopterous insects.

Catha (Arab. khât). A genus of *Celastraceæ* consisting of African shrubs, with spiny branches, simple leaves, and axillary small branching heads of flowers, distinguished from those of *Celastrus* by their five stalkless petals.

CATHARI

The leaves of *C. edulis*, the Khât or Cafa, are used by the Arabs in the preparation of a beverage possessing properties analogous to those of tea and coffee. The use of khât in Arabia is said to be of great antiquity, having preceded that of coffee. The twigs with leaves attached are the parts used. The effects of the decoction are similar to those of strong green tea.

Cathari (Gr. *katharoi*, pure). An Oriental sect of Christians. [PAULICIANS.]

Cathartica (Gr. *kathartika*, from *katharizo*, I purge). That which increases the action of the bowels. The term is commonly applied to medicines which do this with some degree of violence: among the milder cathartics, jalap, senna, calomel, and saline purges are the most used; those which are *drastic* are croton oil and elaterium.

Cathartine. The active or purgative principle of senna.

Cathartocarpus. A name sometimes applied to certain species of *Cassia* which have long black woody cylindrical pods one to two feet long, containing many seeds embedded in a mild laxative pulp. *C. fistula*, the Pudding Pipe-tree, a very handsome Indian tree, with the foliage of the ash and the inflorescence of laburnum, is the best known.

Cathedra (Gr. *a seat*). In mediæval Latin, the 'chair' or seat of a bishop.

Cathedral. The principal church of a diocese, in which is the cathedra or throne of the bishop. The choir of the cathedral church was made in early times to terminate in a semi-circular or polygonal apsis; and in the recess thus formed were placed the throne of the bishop in the centre, and seats of an inferior class for presbyters. In modern cathedrals the bishop's throne is in the choir, and generally on the south side. (Bingham, viii. 6. 10.) [ARAB; ARABIC.]

Catheta and **Cathetus** (Gr. *kathêta*, *adversus*). In Architecture, a vertical line falling from the extremity of the underside of the cy-matium of the Ionic capital through the centre of the volute.

Catheter (Gr.). A tube which may be introduced by the urethra into the bladder for the purpose of drawing off the urine.

Cathode (Gr. *kathodos*, a descent). A term applied by Faraday to the negative pole, or electrode, in the voltaic circuit, the elements there eliminated being called *cations*.

Catholic (Gr. *katholikos*, universal). A word which occurs in the New Testament in the titles of certain of the Epistles—those of James, Peter, and John—signifying that they are addressed to the whole or universal body of Christians, and not to a particular section of them. It was used in primitive times to mark the difference between the Christian church, open to all nations through baptism, and the Jewish, which was ordinarily confined to a single people. 'A catholic church means a branch of this one great society, as the church of England is said to be a catholic church: the catholic church includes all the churches

CATTLE

in the world under their legitimate bishops.' (Hook's *Church Dictionary*). [CRUNCH; HERRING; ROMAN CATHOLIC.]

Catholicon (Gr.). In old Pharmacy, a universal medicine.

[CATODA.]

The Malabar name of *Cajanus indicus*, a kind of pulse much used in the tropics.

Catkin (Dutch, *kattiken*). In Botany, the name applied to the inflorescence of the poplar, willow, and similar trees. A catkin or ament is a close spike, composed of scales overlapping each other; it falls off the parent plant as soon as its office of flowering or fruiting is accomplished.

Catting. A term applied by surgeons to a knife used in amputations.

Catlinite. A reddish variety of clay-stone from the Côteau des Prairies, west of the Mississippi. It is carved into tobacco-pipes by the Indians, and named after Catlin the American traveller.

Catoptrics (Gr. *kattoptrika*, reflexive). Is that part of the science of Optics which treats of the laws of reflected light and the phenomena of vision produced by reflection. [MIRROR; OPTICS; REFLECTION.]

The principal authors who have treated of Catoptrics are Euclid; Alhazen and Vitellion, in the eleventh and twelfth centuries; James Gregory in his *Optica Promota*; Barrow, Smith, Tacquet, and most modern writers on the subject of Light or Optics.

Catopromancy. Divination by means of a mirror.

Catsup. A sauce prepared from mushrooms, walnuts, and other vegetable productions. It is often written ketchup, and is said to come from the Eastern kitjap.

Cattamundee. A gum-elastic obtained from *Euphorbia antiquorum*.

Cattle (Low Lat. *catalla*, *chattels*). Domesticated animals of the cow kind, which are found accompanying man in every civilised country, and in every climate. The native country of the type of British cattle is supposed by some to be Asia; but in this case, as in all others where an animal or a plant has been long in a state of domestication, the origin of the species is involved in obscurity. When the tame cattle of any country are allowed to run wild and breed in that country, uncontrolled by man, the habits which belong to the animal in its savage state become, in the course of three or four generations, modified according to the natural supplies of food and the character of the climate. Hence, though cattle are not indigenous to Britain, South America, or the Sandwich Islands, we have in the former country a breed of wild cattle in one or two gentlemen's parks, as at Chillingham in Northumberland, which are quite different from the wild cattle of the fertile soils of South America, as these again are different from the wild cattle of the Sandwich Islands, though all undoubtedly the descendants of tame animals. Those

in the Sandwich Islands, in particular, are known to be the offspring of the tame cattle that were left there by Vancouver, and which can now be only caught alive by entrapping them in disguised pits; into one of which the unfortunate botanist Douglas fell, and was gored to death by a bull which happened to be in it at the time.

The domestic cattle of Britain may be divided into two principal races: those of large size adapted for the plains, and those of smaller size adapted for the mountains. Of each of these classes there are several breeds; such as the Highland and the Welsh cattle, among the latter; and the Lancashire, the Yorkshire, and the Herefordshire cattle, among the former. There is also an intermediate breed, adapted for moderately hilly countries, such as the Galloway and Fife breeds in Scotland, and the Alderney and Guernsey cattle in England. The shorthorn, Hereford, and Devon are the three leading English meat-producing breeds. The dairy breeds are the shorthorn, longhorn, Ayrshire, Alderney, and Suffolk. The best beef brought to the London market is that of cattle of the Highland breed fed in English pastures, or on turnips. The best milk cow for general purposes is the Ayrshire; the best for cream and butter, the Alderney; and the best for immense quantities of milk, the Lancashire and shorthorns. Hence the latter breeds are generally employed in public dairies, the Ayrshire and Suffolk by farmers and cottagers, and the Alderney by the higher classes.

Catulus (Lat. *the young of anything*). The old botanical name of the catkin of a plant.

Caucasus. This lofty range, almost connecting the mountains of Persia with the Carpathians, and separating the great Aralo-Caspian region from the Black Sea, extends for about 700 miles in a continuous chain, and has several offshoots, or transverse ridges, penetrating both towards Russia and into Asiatic Turkey. The chief elevations are very lofty, the highest being estimated at 18,600 feet, and another peak at no great distance 16,500 feet. These two culminating points occupy nearly the central portion of the main chain, which is rather narrow. The limit of snow is 11,000 feet, and the whole of the central part of the mountain group is full of glaciers.

The Caucasus connects on the east with the lofty table-lands of Asia and Asia Minor, and thus with the serrated snowy range of the Taurus and Armenia, of which Mount Ararat (17,200 feet) is the culminating point. All the mountains of the Caucasus are split and rent by deep gorges, and the valleys afford some of the most remarkable and picturesque mountain scenery that has ever been described. Mount Ararat is a volcanic cone.

Cauda (Lat.). That portion of an animal which is supported by vertebra behind the sacrum; these vertebra, in fishes, bearing in-

ferior spinous processes. In _____ signifies that part of the abdomen which _____ suddenly slender, and terminates in a long jointed tail, as in the scorpion.

Cauda Squamosa (Lat.). In Anatomy, the roots of the terminal spinal nerves which are contained in the neural canal of the vertebra, and surround the 'filum terminale' of the myelon.

Caudate (Lat. *cauda, a tail*). In Anatomy, when the apex of a pyramidal part or organ is prolonged into a long slender point: certain microscopic bodies found in ganglia are termed especially 'caudate' nerve-corpuscles. In Zoology, an animal provided with a tail.

CAUDATA. In Botany, when the apex of any organ in a plant is extended into a long slender point; this is not of rare occurrence, and is especially common in Araceous and Aristolochiaceae plants.

Caudex (Lat. *a trunk*). The Linnaean name of what is now more generally called the axis of vegetation; the woody centre round which the leafy and leaf-like organs are arranged. The *caudex ascendens* was the stem, the *caudex descendens* the root of a plant.

Caudiclea (a diminutive formed from Lat. *caudex*). A thin, elastic, semi-transparent process of the pollen masses of Orchidaceous plants, by means of which the pollen is brought in contact with the stigma or stigmatic gland.

Cauk. [CAWK.]

CAUL. The trivial appellation of the *amnion* when it comes away in childbirth. It is regarded by the superstitious as a charm against shipwreck.

Cauliculus (Lat. *dim. of caulis, a stem*). In Architecture, the small stalks under the volutes of the Corinthian capital, which they seem to support.

CAULICULUS. In Botany, the slender part which connects the cotyledon of a seed with the radicle. It is considered an extension of the stem. Its office is to lengthen rapidly when germination takes place, and thus to bring the true radicle into contact with the earth upon which it has to feed.

Cauliflower (Fr. *chou-fleur*). One of the garden varieties of *Brassica oleracea*, in which the inflorescence while young is condensed into a depressed fleshy esculent head.

Cauline (Lat. *caulis, a stem*). In Botany, anything that grows to, or springs from, the stem of a plant. Thus cauline leaves are those which grow upon the stem; cauline prickles such as are borne by the same part, and so on.

Caulk or **Calk**. To stuff the seams or openings between the planks of a ship with oakum, which is rope untwisted into its original state of fibre. The oakum is forced in by a caulking chisel and mallet. It has been found necessary, when a ship has worked the oakum out of the seams, to fill them with rope. In addition to preventing leakage, caulking affords fixedness to the whole frame, and is therefore a great support. The quantity of oakum used in a large ship is very great:

CAULOCARPOUS

is a first-rate it is nearly thirty tons, or upwards of four cables.

When the seams are caulked, melted pitch is poured on the seams of the decks out of a pitch ladle; in other places it is laid on with a pitch mop: this is called *paying* the seams.

Caulocarpous (Gr. *καυλός*, the stem of a plant, and *καρπός*, fruit). A name applied by De Candolle to plants which, like trees and shrubs, annually produce flowers and fruit on their branches without perishing.

Causality. A miner's term for the light parts of ores which are carried away by washing.

Cause (Lat. *causa*). Four kinds of causes have been distinguished by logicians: the *material*, the *efficient*, the *formal*, and the *final*. The *material* cause of a thing is that out of which that thing is made; in other words, that which is the ground of the possibility of a thing's coming into existence: e. g. the marble out of which a statue is made. The *efficient* cause is that in which resides the moving power requisite in order to render the possible existence actual; as the sculptor. The *formal* cause is that which must supervene to the matter, in order to give the thing its precise individual existence as that thing and no other; as the shape which the sculptor communicates to the marble. This distinction is derived originally from Aristotle, with whom, however, it is rather a metaphysical than a logical determination. The *final* cause of the thing is that very thing in its completeness; as the statue when made. [ARISTOTELIAN PHILOSOPHY.]

In popular language, however, the *final* cause is synonymous with the purpose to which any object is supposed to contribute, though that purpose be wholly external to the thing caused.

Causeway (catachrestic for *causey*, Fr. *chaussée*, a paved road). A carriage road supported at a slight elevation above the surface of any marshlands, or water, which it may be found advisable to traverse; it differs from a viaduct, which is supported by piers and arches, whilst in a causeway the road is carried by an embankment, or by a low retaining wall.

Caustic (Gr. *καυστικός*, from *καίω*, I burn). When rays of light issuing from a luminous point are incident upon a surface separating two media, reflection and refraction take place according to well-known laws, viz. 1. The plane containing the incident and reflected or refracted ray contains the normal of the refracting surface at the point of incidence. 2. The angles of incidence and reflection are equal. 3. The sines of the angles of incidence and refraction have a constant ratio. Now the reflected as well as the refracted rays will by their mutual intersections give rise to a series of points, at which the intensity of light and heat will be in excess. The surface formed by such a series of points, that is to say, the envelope of the reflected or refracted rays, is

CAUSTIC

called a *caustic surface*; the first a *caustic by reflection* or *catoptrical*, the other a *caustic by refraction* or *dioptrical*. The bright lines seen on a table upon which stand a bottle of water and a candle are familiar examples of the two kinds of caustics, or rather of the curves in which the caustic surfaces are intersected by the plane of the table. In the construction of reflectors, lenses, &c. the consideration of caustics is of manifest importance. The caustic by reflection from a paraboloid of revolution reduces itself to a point when the incident rays are parallel to the axis, hence the importance of parabolic reflectors. In the case of reflection from a sphere this property is lost, the caustic surface does not reduce to a point, and hence the phenomenon of spherical aberration.

The determination of caustic surfaces and caustic curves (which have an analogous definition, the reflecting curve and luminous point being in the same plane) is, however, a purely geometrical problem, and as such appears to have been first investigated by the German mathematician Tschirnhausen, who communicated his results to the Academy of Paris in 1682. As included in the more general theory of envelopes, the subject has been since much developed. (J. Bernoulli, *Opera Omnia*, vol. iii.; L'Hôpital, *Analyses des Infiniment Petits*; St. Laurent, *Gergonne's Annales de Mathématique*, vol. xvii.; Quelelet, *Mémoires de l'Académie de Bruxelles*; Malus, *Théorie de la Double Réfraction*, Paris 1810; Sir W. Hamilton, *Transactions of Royal Irish Academy*; Sir J. Herschell 'On Light,' *Encyclopædia Metropolitana*; Cayley, Holditch, and others, *Cambridge and Dublin Mathematical Journal* and *Quarterly Journal of Mathematics*; Dr. Salmon, *Higher Plane Curves*.)

The following are a few of the more remarkable geometrical properties of caustics. If a curve equal and similar to the reflecting curve be allowed to roll upon the latter, so that homologous points may coincide with the point of contact, the point which, with respect to the rolling curve, is homologous to the luminous point, will describe a curve whose evolute is the caustic. In other words the caustic is the evolute of the *double pedal* of the reflecting curve with respect to the luminous point. [PEDAL.] Thus the caustic by reflection from a circle is in general the evolute of an epitrochoid. This epitrochoid, however, the circles being equal, is well known to be a *Limaçon*, a curve of the fourth order belonging to the family of Cartesian ovals. Its evolute, the caustic, is a curve of the sixth order, whose equation was given by St. Laurent (see above). When the incident rays are parallel, the caustic is itself an epicycloid, and a cardioid, when the rays proceed from a point on the reflecting circumference.

The caustic by refraction may also be regarded as an evolute, the corresponding involute being the envelope of a series of circles having their centres on the refracting curve, and their radii proportional to the distances of these centres from the luminous point. This genera-

CAUSTIC, LUNAR

tion of a diacastic, although apparently more complicated than the original one, is in practice often more convenient. Thus the caustic by refraction at a right line is the evolute of an ellipse whose foci are the luminous point and its *image* by reflection. The caustic by refraction at a circle is the evolute of a Cartesian oval, one of whose foci is the luminous point, and whose axis is the line joining this point and the centre of the refracting circle.

Another property common to all caustic curves, and which at an early period served to invest them with great interest, is that they are always rectifiable when the primitive curves are algebraic; in other words, a right line can always be found of the same length as any given arc of a caustic. When the rays, after suffering a single refraction or reflection, meet the same or another surface a second time, a *second* caustic is produced, and in a similar manner a whole series of related caustics may arise.

Caustic, Lunar. Fused nitrate of silver.

Caustics. Substances which corrode and destroy the texture of the skin and of organised bodies.

Cautery (Gr. *kautêrê*, a burner). The ancients divided cauteries into *actual* and *potential*. The former term is applied to red-hot iron; the latter to pure potash.

Cautionary. In Scottish Law, is the obligation by which a party becomes surety for another; answering to the English term guarantee. It is defined by Stair, 'the promise or contract of a man not for himself but another.' The guarantor is termed 'cautioner.'

Cavædium (Lat.). In ancient Architecture, this word was applied to an open quadrangle, or court, within a house. The cavædia described by Vitruvius are of five species: Tuscanicum, Corinthium, Tetrastylon (with four columns); Displuviatum (uncovered); and Testudinatum (vaulted). Some writers make the cavædium the same as the atrium and the vestibulum; but it appears to have been in fact very different from either of those apartments.

Cavalier (Fr. from Latin *caballus*, a pack-horse; Span. *caballero*). This term was used originally in a general sense for a horse soldier; but it has acquired historical importance from its having been applied to the adherents of Charles I. in contradistinction to the *Round-heads* [which see], the supporters of the parliament.

CAVALIER. In Fortification, a sort of interior bastion, several feet more elevated than the principal bastion of the fortress in which it is formed. The use of the cavalier is twofold: it serves either to defile the works from the fire of an enemy on an adjacent height, or to command the trenches of the besiegers. Cavaliers are sometimes constructed in the gorges, or on the middle of the curtain, and their form is the semicircular; but when they are within the bastion they are now built with straight faces and flanks parallel to those of the work in which they are placed. French cavaliers are

CAVALRY

works raised by the besiegers on the glacis of a fortress, for the purpose of enabling them to direct a fire of musketry into the covered way.

Cavalry (Fr. *cavalerie*). A body of soldiers furnished with horses for war. This arm can boast of high antiquity, and is so peculiarly useful and necessary for a great variety of operations, that it has in all ages been held by the greatest generals in high estimation. The efficacy of cavalry arises principally from its adaptation to speedy movements, thus enabling a commander to avail himself immediately of a decisive moment when the enemy exposes a weak point, or when disorder appears in his ranks, for completing his defeat by disconcerting him by a sudden attack. It is singularly useful in protecting the wings and centre of an army, for furnishing detachments, for escorts, for forming blockades, for intercepting the supplies of the enemy, for foraging, for procuring intelligence, for covering a retreat, &c. The successful services which troops of this description have performed, and the number of decisive advantages which have been obtained by means of them in the most important battles of which history ancient and modern furnishes the details, prove incontestably the utility of this arm. The use of cavalry, however, is necessarily limited by the nature of the ground. Open and level countries are favourable to its operations; in forests, in mountainous districts, on a marshy soil, &c. it is but of little avail. Among the Greeks and Romans, the cavalry was regarded as the most respectable class of troops. In the middle ages a similar feeling seems to have prevailed; for, in the early French monarchy, and in the Anglo-Saxon kingdoms of Britain, the men of wealth and noble birth distinguished themselves in the field from those of inferior rank by being well armed and mounted on horses; and from the mode of warfare then practised, as well as from the peculiarities adopted in the organisation of troops, cavalry constituted almost the only efficient arm of battle down to the introduction of standing armies; and only where they could not take their horses, the men-at-arms used to dismount and fight on foot.

In France especially so completely was the foot soldier looked down upon, that at Crecy, Philip of Valois called on his cavalry to cut to pieces his own crossbowmen, or 'rabble' as he called them, because they were in the way.

The use of the long bow by the English archers, who defended themselves from the attack of cavalry by planting stakes before them in the ground, first showed the inefficiency of these armour-clad mounted men; and later the invention of gunpowder, and the subsequent employment of artillery in the field, deprived the heavy-armed cavalry of those times of all the advantages it possessed over the infantry, and rendered its movements awkward and inefficient. It was reserved, however, for Gustavus Adolphus to show the real utility of this arm by discovering the services on which it

CAVATINA

should properly be employed, and by stripping it of all unnecessary encumbrances to supersede by *rapidity of motion* the value it formerly possessed in *weight*. Since that time cavalry has often turned the scale of fortune in war: the battle of Rossbach, for instance, in 1757, one of the most brilliant victories either of ancient or modern times, was entirely decided by this arm.

Modern cavalry consists of two grand classes—*heavy* and *light* horse; which are again susceptible of further subdivisions, according to the purposes to which they are subservient. The British cavalry consists of two regiments of life guards, the royal regiment of horse guards, seven regiments of dragoon guards, and twenty-one regiments, of which three are dragoons, thirteen hussars, and five lancers. (For the history, use, accoutrements, and arms of these different branches, see the separate articles.) A regiment of cavalry is divided into four squadrons, and each of these into two troops. A troop consists of sixty-eight men; and to each troop there is attached a captain, a lieutenant, and a cornet.

Cavatina (Ital.). In Music, a term now usually applied to a vocal piece, for a single voice, extracted from an opera.

Cavea (Lat. *a hollow place*). This term was applied by the Romans to the interior of an amphitheatre. (Ammianus Marcellinus, lib. xxiv. c. i.)

Caveat (Lat.). In Law, a notice or caution given by a party interested to a judge or other officer, in order to stay proceedings by him; as, in the Court of Probate, a caveat is put in to stop the granting of probate or administration.

Cavendish Experiment. An important mechanical experiment for the purpose of ascertaining the mean density of the earth; the method employed being a comparison of the force of terrestrial attraction with that of the attraction of leaden masses of known magnitude and density, determined by means of the balance of torsion.

The idea of rendering sensible and measuring the attractive force exerted by a dense body upon another body in its immediate vicinity by means of the torsion balance, appears to have been suggested by the Rev. John Michell; but the experiment was first actually made by the celebrated Henry Cavendish, whose report is published in the *Philosophical Transactions* for 1798. It was subsequently repeated by Reich, Professor of Physics at Freiberg, in Saxony, who published his results in 1838; and again by the late Francis Baily, with far greater precision, and by a far more varied and extensive series of observations, the details of which are given in a paper of great value published in the *Memoirs of the Royal Astronomical Society*, vol. xiv. 1843.

In the mode of proceeding adopted by Cavendish, and followed by Baily, the data for determining the earth's mean density were obtained in the following manner: A slender deal rod of six feet in length, having a leaden

CAVENDISH EXPERIMENT

ball of about two inches in diameter attached to each of its ends, is suspended horizontally from a beam by a fine metallic wire, about forty inches in length. This forms the torsion balance. Immediately under the balance is placed a strong horizontal plank about eight feet in length, supported by and turning upon an axle, the central line of which is in the same vertical with the suspension wire. On this plank, near its extremities, are placed two equal spheres of lead (twelve inches in diameter, and each weighing about 380 lbs.), cast with great care, in order that the density may be uniform throughout the mass, and accurately turned. The apparatus is so arranged that the centres of the two balls at the extremities of the arm of the torsion balance, and the centres of the two leaden spheres, or *masses*, are in the same horizontal plane, and equally distant from the vertical axis of motion. Suppose now the torsion balance to be at rest in a certain direction, and the plank which supports the masses to be at right angles to the direction of the balance; in this position the attraction of the two masses will have no tendency to give motion to the balance. But let the beam be turned round till the two masses approach near to the balls, then the attraction of each mass, acting most powerfully on the nearest ball, tends to bring the masses and balls still closer together. A motion is thus given to the arm of the torsion balance, and in consequence of the elasticity of the suspension wire, the balance performs a series of isochronous oscillations and ultimately comes to rest in a position in which the attraction of the two masses on the balls is exactly counterbalanced by the torsion of the wire.

The force developed by the leaden masses being exceedingly minute, not more than a fifty-millionth part of their weight, a very small disturbing force will prevent the success of the experiment, and accordingly many precautions are requisite. In Baily's experiments the torsion rod was enclosed in a mahogany case, gilt in the inside, wrapped round with thick flannel, and covered over with gilt paper, to prevent the radiation of heat, and consequent derangement from the currents of air thereby produced. The balls were also gilt and burnished, and the whole apparatus was surrounded by a close wooden frame, or case, having glazed openings, through which the motions of the torsion rod were observed by means of a telescope from a distant part of the room.

In order to deduce the mean density of the earth from the data furnished by the experiments, it is necessary to find expressions for the torsion developed in the wire, and for the attractive force of the masses on the balls, in that position of the arm of the balance at which it comes to rest under the action of the two forces, which then counterbalance each other. The theory is as follows:—

Let F denote the force (measured by the weight in grains) which, being applied hori-

CAVENDISH EXPERIMENT

zonally and perpendicularly to the arm of the balance at the unit of distance (one inch) from the suspension wire, causes the arm to pass through a unit of angular space, or describe an arc equal to the radius. Also, let F' denote the torsion actually developed by the attraction of the masses, a the distance of the suspension wire from the centre of the ball, and θ the angle of deviation of the arm from its first position. By the nature of the lever, the force required to produce a given effect is inversely as the distance of its point of application from the fulcrum, which is here the suspension wire; and according to the law determined by Coulomb, the force of torsion is directly proportional to the angle of torsion; therefore,

$$F' = F \frac{\theta}{a}$$

The measure of this force F' is deduced from the time in which the oscillations of the balance are performed. The general formula [TORSION] for the torsion force is,

$$F = \frac{\pi^2}{n^2} \times \text{moment of inertia,}$$

where $\pi = 3.14159$, and n is the number of seconds in the time of an oscillation. In the present case the whole of the matter in each ball may be regarded as accumulated at its centre, and the matter in the rod may be neglected; hence in respect of each ball the moment of inertia is expressed by the mass (m) multiplied into the square of the distance of its centre (a) from the suspension wire, that is, by a^2m , consequently the inertia in respect of both balls is $2a^2m$, and the above formula becomes

$$F = \frac{2\pi^2}{n^2} a^2m.$$

Let w denote the weight in grains in each ball, g the accelerating force of gravity, and l the length of the seconds pendulum; then $w = gm$, and $g = \pi^2 l$, whence by substitution $F = \frac{2a^2w}{ln^2}$, and consequently, since $F' = F \frac{\theta}{a}$, $F' = \frac{2aw\theta}{ln^2}$.

Having obtained an expression for the torsion force, we have next to find the force of the attraction of the leaden masses. In respect of each mass let g' denote the force of attraction, r the radius, v the volume, and d the density; and in respect of the earth (assumed to be a sphere) let the same elements be respectively denoted by g , R , V , and D ; also, let k denote the distance of the centre of the mass from the centre of the ball at the middle of the oscillation, and assume f to be the coefficient of gravity. Now, because the attraction of a sphere on a point without it is directly as its mass, that is, as its volume multiplied into its density, and inversely as the square of the distance of the attracted point from its centre, we have $g' = \frac{fvd}{k^2}$, and $g = \frac{fVD}{R^2}$,

whence $\frac{g'}{g} = \frac{vdR^2}{VDk^2}$. But $\frac{r^3}{R^3} = \frac{v}{V}$, therefore

$\frac{g'}{g} = \frac{r^3d}{RDk^2}$; consequently, since the attraction of the earth upon the ball is the same thing as the weight of the ball, or $g = w$, we have $g' = \frac{r^3dw}{RDk^2}$ and therefore

$$\text{attraction of both masses} = \frac{2r^3dw}{RDk^2}$$

By the conditions of the problem this attraction is equal to, or balances, the torsion force F' ; therefore, putting the two expressions equal to each other, we have $\frac{a\theta}{ln^2} = \frac{r^3d}{RDk^2}$; whence, finally, $D = \frac{r^3ld}{aRk} = \frac{\pi^2}{\theta}$

In this expression for D , the mean density of the earth, all the quantities are supposed to be known excepting n and θ , and the object of the experiment is to determine their values. The angle θ is determined by observing the number of divisions, on a known scale, passed over by an index or pointer attached to the extremity of the arm of the balance, so that if β denote the value of one division of the scale in parts of an inch, λ the distance in inches between the suspension wire and the extremity of the index, and h the number of divisions passed over by the index when the arm of the balance moves from its position of rest *before* the mass is approximated to the ball, to its position of rest *after* the approximation, then $\theta = \frac{h\beta}{\lambda}$.

Cavendish gives the numerical values of the constants which enter into the expression for D as follows: $r = 6$, $l = 39.14$, $a = 36.65$, $k = 8.85$, $R = 250800000$, all in inches; and ω (the density of the leaden mass as compared with water) = 10.64. He also had $\beta = \frac{1}{30}$, $\lambda = 38.3$, whence $\theta = 1.766$; and the substitution of these numbers in the formula gives $D = \frac{\pi^2}{10683h}$. There are, however, several

corrections to be made on account of the attraction of the matter in the plank and mahogany case, and other parts of the apparatus, as also for the inertia of the arm of the balance, and for the variation of the masses on the balls according to the position of the arm, for the details of which we must refer to the memoir of Baily already cited. It may be noticed that the motion of the arm is very slow, the average time of a complete vibration in Cavendish's experiments having been from six to seven minutes.

The result obtained by Cavendish gave the mean density of the earth, as deduced from 17 sets of experiments, equal to 5.45, that of water being unity. Reich, from 57 experiments, found it to be 5.44. Baily's experiments were far more numerous and varied than those of his two predecessors. The torsion rod was suspended in different ways: by a single copper wire, as had been practised by Cavendish and Reich; and by double lines, as proposed by

CAVERNS

Gauss; and in the latter case the substances used were silk fibres, brass wire, and iron wire. In order to ascertain whether the results would be affected in any way by varying the substance of the attracted body, the experiment was made not only with leaden balls attached to the ends of the torsion balance, but also with balls of platina, zinc, glass, ivory, and hollow brass, and with a torsion rod of brass without balls. The actual number of experiments recorded in the memoir is no fewer than 2,163; and nearly as many more, which had been made before the anomalies of the balance had been entirely got rid of, were rejected. The mean result from all the recorded experiments, without exception, gave the mean density of the earth equal to 5.675, with a probable error of .0038.

Caverns (Lat. caverna). Few rocks are so compact as not to show occasionally hollow spaces and recesses, to which the name Cavern may properly be applied; but limestone caverns are so much the most numerous, the largest, the most important, and the most interesting of all, that they have attracted universal attention and caused the others to be neglected. Limestone caverns are certainly among the grandest and most instructive phenomena presented in nature. Vast natural tunnels penetrating for miles into the heart of the earth, multiplied infinitely by ramifications too small for man to follow, but quite large enough to allow of open water communication underground from one part of a country to another, are found in all limestone districts wherever the rock is hard and compact enough to form a durable roof. Such a rock is so broken, during hardening and elevation, as to admit of the percolation of water, and nothing but a sufficient rainfall is necessary to insure a constant supply of water, which, running through the crevices, enlarges and multiplies them, and ends by producing a group of caverns.

The foundation of all that is remarkable in these caverns is the solubility of limestone in water. Wherever rain falls and enters the earth, it dissolves some portion of the limestone with which it comes in contact. Small as this may be, still if the water constantly courses through the same crevices, the result will soon become evident. The water continues to flow; but when saturated with carbonate of lime, it is in a condition to redeposit it if circumstances are favourable. Where it is stopped in its progress, and where part of the water is evaporated by the air that also passes through the cavern, this redeposit takes place, for by the removal of the water the dissolved carbonate of lime is left behind. It is either added to a pendant suspended from the ceiling or roof of the cavern, or to a column rising from the floor where a constant drip takes place. Thus the limestone removed from the walls of a crevice a long way overhead may serve to produce in the interior an additional film on a portion of a column, which is a *stalactite* or *stalagmite* according as the water drips from or upon it.

CAVETTO

It is quite impossible to exaggerate the amount of complication producible by these simple means, namely, the removal of portions of limestone from one place and their depositions in another. The caverns originate in crevices formed by the irregular fracture of the rock. Out of these hollow spaces are concocted by the action of running water natural chambers of all dimensions. Into these hollow spaces again are packed away the most fanciful and singular examples of nature's handiwork, imitative as it were of human devices. Columns, pilasters, churches, sculptured groups of men and animals, organs, curtains, and almost all conceivable objects, are found or fancied by those who thread the narrow passages or cross the lofty halls with a few glimmering lights to guide them in their way.

The celebrated grotto of Antiparos in Greece, the Adelsberg caverns in Carniola, the Mammoth Caves of Kentucky, the caverns in Bavarian Switzerland, and a host of others in France, Belgium, Spain, Sicily, Hungary, &c.; others in the principal limestone districts of England as in Somersetshire, Derbyshire, and Yorkshire; others again in the Brazils; others in Australia, are all essentially of the same nature. They are results of water action on broken and fractured limestones.

Granite also is frequently penetrated by water on a sea coast and is worn into caverns. The shores of the Channel Islands and the coasts of Brittany and Cornwall are alike examples of this. But here the action of water is chiefly mechanical, and the result is on a smaller scale. The water penetrates the softer parts of the rocks, undermines them, and assisted by the constant tidal action of the waves (removing all broken material that comes within its influence) it at length produces systems of caverns on a large scale.

The contents of caverns are sometimes extremely interesting. Granite caverns where the range of tide is considerable are sometimes covered with the lower forms of animal life, such as zoophytes and sponges. Limestone caverns are more frequently traversed by fresh than salt water, but they also are favourable for the growth of marine plants and animals of considerable interest.

It is, however, chiefly the materials buried in the floor, and often cemented by and covered up with limestone, that are most interesting in limestone caverns. Bones of quadrupeds are sometimes so abundant that it is difficult to understand how so many can have been accumulated. They are generally the bones of extinct animals, bears, hyenas, elephants, and rhinoceroses, and with them occasionally are indications of men. Thus caverns are crowded with interest of all kinds to the geologist, the archaeologist, the naturalist, and the artist, and few natural phenomena are more striking and varied than those which they present.

Cavetto (Ital.). A hollow moulding used in Architecture, whose profile is a quadrant

CAVIA

of a circle; it is commonly introduced in cornices.

Cavia. The Linnæan generic name of a Cuvierian family of Rodenta, including the guinea-pig, Aguti, Paca, and Capibara.

Caviars. The salted roe of the sturgeon, much esteemed by the Russians as an article of food, and frequently brought as a delicacy to this country.

Cavibornas, Caviicornia (Lat. *cavus*, hollow, and *cornu*, horn). The name of the tribe of Ruminants comprehending those which have the horns hollowed out like a sheath and implanted on bony processes of the os frontis, as in the antelope.

Cavities, Entozoa Cavitaria (Lat. *cavitas*, a hollow). Intestinal worms, or Entozoa, which have an intestinal canal floating in a distinct abdominal cavity.

Cawk. A term applied by miners to a massive earthy-looking variety of sulphate of baryta, which is very common in Derbyshire.

Cauleyan. The envelope of the pairs of right lines which constitute polar conics relative to a cubic curve, or, what is the same thing, the envelope of the right lines joining corresponding points of the Hessian of the cubic. The name was proposed by Cremona, in his *Teoria Geometrica delle Curve Piane*. The curve in question is of the third class and sixth degree, whose properties were first investigated by Cayley in the *Phil. Trans.* of 1857. It has since been referred to by several English and Continental writers; a short notice of it is given in Salmon's *Higher Algebra*, p. 113—its tangential equation being the first evectant of the fundamental quartic invariant of the cubic.

Cayman or Calman. A name which, according to Marcgrave, is applied to the crocodiles by the negroes of Congo. It has been diffused over the new continent by the negroes, and applied to most of the American species indiscriminately; but by Cuvier it is restricted to the alligators. [ALLIGATOR.]

Cebadilla. The seeds of *Asagraea officinalis*, from which veratria is obtained.

Cebus (Gr. *κῆβος*, a monkey). A genus of Platyrrhine prehensile tailed monkeys found in equatorial America. Many species are known to zoologists, presenting more or less amount of variation. The specific value of these forms has been contested by many zoologists, who have proposed to refer nearly all of them to one or two species. The *Cebus apella* and *capucinus*, which are found near the Orinoco, are examples of the genus.

Cecropia (Cecrops, a mythical king of Athens). A genus of *Artocarpaceæ*, occurring in tropical South America, and having the very minute flowers arranged on short cylindrical spikes, several enclosed within a large bract. The female flowers are succeeded by short spikes of fleshy one-seeded fruits. *C. peltata* is the Trumpet-tree of the West Indies, its hollow branches being used for musical instruments, and its hollow stems for drums. The bark is

CELERES

astringent. The wood is light, and when dry is used by the Indians for producing fire by means of friction.

Cedar (Lat. *cedrus*, Gr. *κῆδος*). The common name of various trees, but more especially applied to the Cedar of Lebanon (*Abies Cedrus*) and the plants closely allied to it.

Cedrelaceæ (Cédrela, one of the genera). A very important, though small, natural order of plants, allied to *Miliaceæ*, from which they differ in having winged indefinite seeds. They belong to the Rutal alliance, and have consolidated capsules and either deeply monadelphous or free stamens. Most of the species are trees of large size. *Swietenia Mahagoni* yields mahogany, in the woods of the Spanish Main; from *Chloroxylon Swietenia* comes Indian Satinwood; while the Yellow-wood and the Cedar of New Holland are the produce of others. In general their bark is powerfully astringent; that of *Soymida febrifuga* and mahogany itself is a potent febrifuge; that of *Cedrela Tona* is a most valuable tonic in the Malayan archipelago; and *Khaya senegalensis* yields a similar remedy for the dangerous fevers of the Gold Coast.

Cedriret. An orange-red crystalline body contained in creosote.

Cedrus. [CEDAR.]

Ceiling (formerly written *seeding*: derivation uncertain). The upper, or horizontal, or curved surface of an apartment, opposed to the floor, usually finished with plasterer's work; it also in some parts of the country means the rendering coat of a partition. In executing ceilings the best method is to nail the laths to ceiling joists, or to brackets, and to add the work in a series of coats composed of lime and hair, patty, or plaster, technically called gauged stuff; common ceilings are executed with plaster without hair, the same as the finishing coat in walls left for paper.

Celastraceæ (Celastrus, one of the genera). A natural order of shrubby Exogens, formerly confounded with *Rhamnaceæ*, but separated by Brown, chiefly because of the relation which the stamens bear to the petals and the different aestivation of the calyx. They are allied, according to Brongniart, to *Malpighiaceæ*, through *Hippocrateæ*, a small order which scarcely differs from this. *Celastraceæ* are natives of the warmer climates, especially of the tropics, and their general characters appear to be of a stimulating acrid nature. The Khât of the Arabs is procured from *Catha edulis*.

Celeres (Lat.). In the traditional history of Rome, a body of cavalry instituted by Romulus. They consisted of those among the citizens who were rich enough to furnish a horse. They are said to have been 300 in number, and to have been subdivided into three centuries, under the name of Ramnes, Titenses, and Luceres. It is said that the number of the centuries of the Celeres was raised to six by Tarquinius Priscus, and that this was the origin of the Equites or knights, who in after times formed a separate class of citizens. (See

CELESTINE

Sir G. C. Lewis, *Credibility of Early Roman History*, i. 414.)

Celestine (Lat. *celum, the sky*). Native sulphate of strontia. When pure it consists of 43.6 per cent. of sulphuric acid and 56.4 of strontia; but it is often mixed with the carbonates of lime and baryta, or with oxide of iron. It occurs crystallised, fibrous, stellated, and massive, and is colourless, grey, and sometimes of delicate tints of blue, approaching to sky-blue; whence the name Celestine. It is very brittle, has a shining lustre, and varies from transparency to subtranslucence.

Considerable quantities of Celestine are found in the New Red Marl of the neighbourhood of Bristol, where it is made into nitrate of strontia, which forms the basis of the 'red-fire' used at the theatres and in pyrotechny. Fine transparent prismatic crystals are found associated with sulphur and gypsum in the sulphur mines of Sicily. Other localities are Edinburgh, Conil in Spain, Bex in Switzerland, France, Hungary, Dornberg near Jena, Franktown in Pennsylvania, &c.

Celestines. A religious order, so called from its founder, Peter Morrone, afterwards Pope Celestine V., who established it A.D. 1254. It was suppressed A.D. 1778.

Celibacy (Lat. *celibe, unmarried*). The legal condition of unmarried persons. This condition was subjected by the laws of the Roman emperors to a variety of penal consequences. The most remarkable of their enactments, and that on which the subsequent jurisprudence on this subject was in a great measure founded, was the *Lex Julia* or *Papia-Poppæa*, enacted under the authorisation of Augustus. By these laws unmarried persons could receive nothing by will from strangers, and were subjected to many other legal disabilities [LAW, ROMAN]; from which, however, they were successively relieved by later laws passed in the decline of the empire, and especially after the mistaken seal of the Christian divines of that age had invested celibacy with attributes of sanctity. It was at an early period in the history of the Christian church that ministers were exhorted to celibacy by those who laid claims to a higher degree of sanctity. At the council of Nice, in A.D. 325, the proposition to enforce it as a general law was rejected. But at that of Arles, in 340, it was adopted; married persons being indeed held admissible into the church, but only on the terms of separating from their wives on ordination. It had become the common practice of the Latin church in the reign of Gregory the Great (and of the sixth century), and was more fully enforced, after a period of relaxation, in the eleventh. It was proposed to the council of Trent by Charles V. (in the interim), that married priests should retain their wives; but this was rejected. In the Greek church, celibacy was ordained for bishops at the council of Trullo, A.D. 695; but men below the degree of episcopacy are not to marry. Hence the higher digni-

CEMENT

ties of that church are necessarily filled by monks.

Cell. In Anatomy, a primary microscopic vesicle, of larger average size than the nucleus, composed of membranous cell-walls, with usually liquid contents, round or oval, and sometimes flattened like a scale. With a few exceptions—a g. the mammalian blood-discs and old cells of the epidermal or adipose systems—the primary cell contains a nucleus.

Cella (Lat.). In ancient Architecture, the part of a temple within the walls was called the cella; or in Greek the *naos*. The part of the temple in front of the cella was called the *pronaos*; the part in the rear of it, the *posticum*.

Celliperes, Celloperes (Lat. *cella, a cell, and porus, a pore*). A genus of flexible cellular Polyps, including those in which each of the cells is pierced with a minute pore.

Cellular Beam. An application of wrought iron for the purposes of girders and beams, in which wrought-iron plates are riveted with angle irons, in the form of longitudinal cells with occasional cross struts. The experiments on which engineers have founded their practice in the application of these beams may be found in Fairbairn *On Cast and Wrought Iron*, and in Clark, *Britannia and Conway Bridge*; from the last of which the following empirical rule is derived: Make the depth equal to $\frac{1}{4}$ of the length; calculate the dimensions of the lower flanges so that the tension shall not exceed five tons on the square inch, taking the tension at twice the sum of the load to be carried, and the weight of the beam itself; make the sectional area of the top flange one-fourth (or one-third) more than that of the bottom, and the sectional area of the two sides equal to about half the area of the bottom.

Cellular Membrane. In Anatomy. [MEMBRANE.]

Cellular Tissue. In Botany, a substance consisting of little bladders or vesicles of various figures adhering together in masses. It constitutes the principal part of all plants, and may be regarded as an organic basis, into which other kinds of tissue are introduced, or from which they are created. It exists exclusively in the embryo of a plant until vitality has been excited, and new forms of tissue developed in consequence. [BOTANY.]

Cellulose. The name of the matter composing the walls of the cells and vessels of plants. It is insoluble in most menstrua, and is generally characterised by chemical inactivity.

Cement (Fr. *ciment*; Lat. *cimentum, rubric, or mortar*). In Anatomy, the substance which joins together the plates of compound teeth, like those of the elephant, and which fills up the folds and cavities in the teeth of Ruminants and Pachyderms; and which also covers all that part of a simple tooth which is not coated with enamel. The cement is characterised, like true bone, by the presence of the Purkinjean corpuscles.

Cement. In Building, a mixture of carbonate of lime and silicate of alumina in the

CEMENTATION

proportions of 16 to 64 per cent. of the latter to 84 to 36 of the former, which possesses the faculty of setting rapidly under water, and of increasing in hardness with time. There are two descriptions of cements, the *natural* and the *artificial*. The former is obtained by calcining natural stones; the latter is obtained by the calcination of a mixture of chalk and clay. The Roman cements are types of the first class, and Portland cements of the second; these names having reference to some supposed resemblance to Roman mortars and to Portland stone.

Cementation. When a solid body is surrounded by the powder of other substances, and the whole heated to redness, the process is termed *cementation*. Iron is said to be converted into steel by cementation with charcoal.

Cemetery (Gr. *νομῆριον*, a place for sleeping). In Architecture, an area or a building wherein the dead are interred. The most celebrated public cemeteries of Europe are those of Naples, Bologna, Pisa, the more modern one of Père la Chaise of Paris, and that at Kensal Green near London. That of Pisa is particularly distinguished by the beauty of its form and architecture, which is early Italian Gothic. It is 490 feet long, 170 feet wide, and 60 feet high, cloistered round the four sides, and contains many shiploads of earth which the Pisans brought from Jerusalem. It was long a matter of regret that England could boast of no public cemetery; but in 1832 a company was established for the construction of the first undertaking of this description, and it accomplished its object by the creation of the Kensal Green cemetery. Subsequently to that operation, numerous other cemeteries have been established in the outskirts of London; and now that intramural interments are forbidden, there can be no longer any doubt of their advantages, whether the feelings of the living, or respect for the dead, be considered.

Cesneble (Gr. *κρυόβλες*, living in common). A term invented by Mirbel to denote a regular fruit divided from the base into several acapalous pericarps; that is to say, pericarps not marked on the summit by the stigmatic scar, the style having been inserted at their base, as in *Labiata*, *Borraginacea*, &c.

Cenotaph (Gr. *κενὸς τάφος*). A monument, or a tomb, erected to the memory of some person buried elsewhere, or not found for burial at all.

Censor (Lat.). In Ancient History, the title of two Roman magistrates originally created for the purpose of taking the census, or register of the number and property of citizens. But their powers were much increased subsequently, when they had the inspection of the morals of the citizens committed to them, with authority to degrade senators and knights from their respective orders, and remove other citizens from their tribes, depriving them of all their privileges except liberty; which was termed making them *Ærarians*. They had also the power of making contracts for public buildings and the supply of victims for sacrifices.

CENTIGRADE DIVISION

The censors were originally appointed for a whole lustrum; but by law of Mamercus Æmilius, A.C. 433, the term of office was limited to eighteen months. The magistracy was confined to patricians, until C. Marcus Rutilius, a plebeian, was elected in A.C. 361. No person might be twice invested with it; and if one of the censors died, another was not substituted in his room, but his surviving colleague was obliged to resign. The office of censor was abolished under the emperors, who, however, exercised the greater part of its functions.

Census (Lat.). In Roman History, a population return of the citizens, including a valuation of each man's property, and a registration of his tribe, family, children, and servants.

The secondary senses of the word are: a tax levied according to the above-mentioned valuation; and the amount of any individual's property.

The term *Census*, in modern political phraseology, signifies an enumeration of the inhabitants of the country; such as has taken place in England by Act of Parliament every ten years from 1801 to 1861.

Centaurus (Gr. *κένταυρος*). In Greek Mythology, a fabulous race of beings, half-man and half-horse, who are said to have inhabited part of Thessaly, and waged constant war with the hostile tribe of Lapithæ. The word is identified with the Vedic Gandharva. (Bréal, *Le Mythe d'Edipe*, p. 10.)

Centaurus, the Centaur. One of the forty-eight ancient constellations formed by Ptolemy, situated in the southern hemisphere, and under the tail of Hydra. The Centaur is represented as half-man, half-horse; the human part only of the figure is visible above our horizon.

Centigrade Division. The division into *grades* or degrees by hundredth parts. A unit of any denomination being divided into 100 equal parts, forms a centigrade scale; but the term most frequently occurs in scientific works, in reference to the division of the scale of the thermometer. The fixed points of the thermometric scale are the points at which water freezes on the one hand, and boils on the other; the space between these two points being divided into 100°, the centigrade scale is formed. In Fahrenheit's scale, which is usually applied in common life to the thermometer in this country, the same space is divided into 180°; a degree of the centigrade scale is therefore greater than a degree of Fahrenheit in the proportion of 180 to 100, or of 9 to 5. Any number of degrees, therefore, on the centigrade scale, being multiplied by 9 and divided by 5, will give the equivalent number of degrees of Fahrenheit. But in comparing temperatures expressed by the two scales, it is necessary to recollect that the zero of Fahrenheit's scale is not placed at the freezing point, but 32° below it. An example will best show how this is to be taken into account. Let it be required to express on Fahrenheit's scale the temperature corresponding to 10° centigrade. Here

$10 \times 9 + 5 = 18$; to this add 32, and we have $18 + 32 = 50$; so that a temperature of 10° of the centigrade scale corresponds to one of 50° of Fahrenheit's. [THERMOMETER.]

Centipede (Lat. *centipeda*). The name of the Myriapodous insects belonging to the genus *Scolopendra* of Linnaeus. They are wingless; and the largest species possess, when full grown, more than fifty and less than two hundred pairs of feet.

Cento (Lat.; Gr. *κέντρον*, a patchwork cloak or garment). A word employed to designate a collection of separate verses from the works of one or more poets, arranged so as to form a distinct poem. The only classical example of a cento left to us is that of Ausonius who composed a nuptial idyll out of Virgilian verses; in which, however, the words are also perverted into a new meaning. In his prologue to this piece Ausonius describes the cento, and gives rules for its composition.

Central Axis. [COMPOSITION AND RESOLUTION OF FORCES AND ROTATIONS.]

Central Forces. Forces, whether attractive or repulsive, whose directions always pass through a fixed point. On account of its applications to the great problems of physical astronomy, the theory of central forces is justly considered as one of the most important in mechanics, and as such receives due consideration in every good treatise on the subject.

The two most important laws of central forces have reference to the description of areas by the radius vector to the moving body, and to the variation of the *vis viva* or product of the mass of that body into the square of its velocity. According to the first, equal sectorial areas are described by the radius vector in equal times, no matter what may be the law of the central force, that is to say the variation of its intensity with the distance of the body, or the position of the body in its orbit. According to the second, the gain or loss of *vis viva* during the passage of the body from one point to another of its orbit depends solely upon the distances of these points from the centre, and not upon the nature of the orbit. It follows as a consequence of the first of these laws, that the velocity of the body at any point of its orbit is inversely proportional to the perpendicular let fall from the centre upon the tangent at that point.

Again, the orbit and centre of force being known, the law of the latter can be determined; and conversely, the centre and law of force being given, the nature of the orbit can be found, its precise form and magnitude depending then merely upon the velocity and direction of the body's motion at any one particular point. Thus a body in motion under the action of a central attractive force directly proportional to the distance would necessarily describe an ellipse *concentric* with the force, and the periodic time would be independent of the magnitude of this ellipse and dependent solely upon the absolute magnitude of the force—to the square root of. In fact, it would be inversely

proportional. On the other hand, the orbit being an ellipse and the centre of force coincident with one of its foci, this force must vary inversely as the square of the distance, and the square of the periodic time must be directly proportional to the cube of the semi axis major of the orbit and inversely proportional to the absolute intensity of the force.

Now according to Kepler's observations the heliacal radius vector of every planet of our system describes equal areas in equal times, the orbit of every planet is an ellipse in one of whose foci the sun is situated, and the squares of the periodic times of the several planets are proportional to the cubes of the semi major axes of their orbits; whence Newton was able to infer, first, that the planets were acted upon by central forces whose source is the sun; secondly, that each of these forces varied inversely as the square of the distance; and lastly, that the absolute central force is the same for all the planets. Thus the great problems of celestial mechanics were completely solved, and the universality of gravitation, that is to say the action of the planets on each other according to the same laws, was afterwards found sufficient not only to account for the secondary irregularities which more accurate observation has detected in the orbits of the celestial bodies, but to predict the existence of one (Neptune) which had not hitherto been observed.

Central Sun. In Sidereal Astronomy, the name given to the body about which the sun, and all the stars in the great cluster or nebula to which the sun belongs, is assumed to be revolving. M. Mädler, of Dorpat, has published a paper under this title, in which he attempts to assign the real motions of the stars, and consequently the position of the central point, in reference to a dynamical theory. He thinks there is no reason for supposing that there exists anywhere a star of such magnitude as to dominate the motions of others as the sun does the motions of the planets; but if we suppose the stars of our stellar cluster to be pretty uniformly distributed, and the form of the limit of the cluster to be nearly spherical, or a surface compressed between two planes, as is supposed to be the case of the Milky Way, then, whatever the law of attraction may be, the stars near the centre will move with much smaller linear velocity than the distant one; and this difference of real velocity will give rise to apparent motions by comparison of which the relative distances from the centre may be assigned. Applying these considerations to the apparent motions actually observed, and assuming the direction of the sun's motion in the heavens to be that which has been determined by Argelander and others, Mädler shows that a point somewhere in the group of the Pleiades, and probably not far from the star α Tauri, possesses the characteristics of the central point. Having thus obtained, approximately, the position of the central body, Mädler proceeds to discuss its probable distance from our sun, and the velocity

CENTRE

of the sun's orbital motion about the centre. Assuming the star 61 *Cygni* to be at the same distance from the central body as the sun is, and the distance of 61 *Cygni* from the sun to be known from the parallax found by Bessel, he finds from these assumptions, and from the observed proper motions of 61 *Cygni* and η *Tauri*, that the parallax of η *Tauri* is $0^{\circ}.0061$, or that its distance is thirty-four millions of times as great as the distance of the earth from the sun. The proper motion of η *Tauri* gives for the periodic time of our sun round the centre 18,200,000 years; and the velocity of our sun in its orbit round the central sun is about thirty English miles in a second of time. (*Monthly Notices of the Royal Astronomical Society*, vol. vii. No. 12, February 1847.)

Centre (Gr. *κέντρον*, a sharp point). The meanings of this word as employed in Geometry and Mechanics are so varied, that a general definition is scarcely possible. It will be best, therefore, to consider separately, and in their proper places, the most important applications of the term.

When applied to a curve or surface, the term Centre or Geometrical Centre denotes a point with respect to which all the points of the curve or surface are symmetrically situated; that is to say, every right line through the centre of a curve or surface will cut the latter in points which, taken two and two, are equidistant from that centre. With respect to curves and surfaces of the second order, the position and properties of the centre are well known, and are fully described in every treatise on the subject. The centres of curves and surfaces of higher order have been less studied; a valuable memoir on the subject, by Steiner, will be found in *Crelle's Journal*, vol. xlviii. p. 7.

For curves of an odd order it is evident that the centre must be a point of inflexion on the curve itself; whilst for those of even order the centre will not in general be on the curve; should it do so, however, it would necessarily be a multiple point of an even order.

In order that a and b may be the co-ordinates of the centre of a curve of the n^{th} order whose equation is $F(x, y) = 0$, all the terms of the $(n-1)^{\text{th}}$, $(n-3)^{\text{th}}$, $(n-5)^{\text{th}}$ &c. dimension in the transformed expression $F(x+a, y+b)$ must vanish. This will give $\frac{(n+1)^2}{2}$ or $\frac{n(n+2)}{4}$ conditions according as n is odd or even. Now the greatest number of conditions that the curve can satisfy is $\frac{n(n+3)}{2}$, so that besides having a centre at a given point, only $\frac{1}{2}(n^2+4n-1)$ additional conditions can be imposed upon a curve of odd order, and only $\frac{1}{2}n(n+4)$ upon a curve of even order. Thus a conic is determined by its centre and 3 points through which it passes; a cubic by its centre and 5 points. To demand that a curve shall possess a centre is equivalent to imposing $\frac{1}{2}(n^2+2n-7)$ or $\frac{1}{2}(n^2+2n-8)$ conditions according as the order is odd or

even; so that it is only in the case of conics that such a demand is without influence upon the number of other impossible conditions. For instance, through 8 points we cannot in general draw a cubic which shall have a centre; through 7, however, we can; and Steiner shows that, in general, the problem is susceptible of nine distinct solutions.

CENTRE. In Building, the temporary support, or framing, on which the materials of an arch are laid, during the progress of the work. The rigidity of such framing, and the ease with which it may be struck, have considerable influence upon the successful execution of the arch; and therefore centring has always constituted an important branch of carpentry.

As a rule, the frames which support the centring are brought as close together as possible, and they are usually made about seven feet apart. They are made to bear either directly on the piers; or they may rest upon struts; or they may have intermediate bearings, which will diminish the clear span. Upon these frames are placed the boards, or laggings, intended to receive the intrados of the arch; when small materials, such as rubble-stone or bricks, are used, the laggings are laid with a close joint; when the work is executed in large wrought stones, the laggings are laid at intervals. When a level tie beam is omitted so as to leave head room in a centre above the springing of the arch, such a centre is called a *socket centre*. In designing a centre of large span, the important principles are: 1st. That the frames should be put together so as to resolve all the thrusts into vertical efforts upon their points of support; 2nd. That the frames should be maintained in their vertical position; 3rd. That the tendency of the centre to rise towards the crown under the influence of the masonry should be counteracted; and 4th. That the centre should be able easily to be withdrawn. In executing an arch the custom is to carry up the two sides equally, and to weight the crown, so as to avoid any deformation of the centres; and most constructors exaggerate the height of this portion of the centre in order to compensate for the compression of the joints; in the old bridges this compression was very considerable, but in modern works it is almost entirely obviated. In striking the centres, care must be taken that there be no unnecessary jar to the masonry; a condition which is hardly to be avoided with the ordinary method of resting the foot of the centres on wedges. (Perronet, *Mémoire sur le Centrement et le Décintrement*, Paris 1809; Robison, *Mechanical Philosophy*, London 1822; Tredgold, *Carpentry*, London 1828; Simms' *Practical Tunnelling*, London 1844.)

Centre of Buoyancy. [**HYDROSTATICS.**]

Centre of Curvature. The centre of the circle of curvature. [**CURVATURE.**] In plane curves the centre of curvature is the intersection point of consecutive normals, and its locus is the evolute. In non-plane curves it is usually distinguished as the *centre of absolute* or *principal*

CENTRE

caustic; it is the point where the osculating plane is pierced by the intersection line of two consecutive normal planes. Its locus is no longer, as in plane curves, an evolute of the curve, though this locus is situated on the polar developable which contains all such evolutes. [**CAUST.**]

Centre of Equilibrium. A point from which, if a system of bodies were suspended, the whole would remain in equilibrium. Thus, the fulcrum or point of support of a lever is its centre of equilibrium.

Centre of Figure. By this term is generally understood the centre of gravity of the figure, considered as a homogeneous body having weight.

Centre of Gravity. The point through which the resultant of the weights of the several component particles of a body always passes. These weights are of course considered as forming a system of parallel forces; the earth's centre, towards which each particle is really attracted, being infinitely distant when compared with the dimensions of bodies with which we are concerned. The existence of such a point as the one defined may be easily estab-

parallel forces to AB may be altered. For instance, if without altering the parallelism or the magnitudes of P and Q , their directions were changed to AP_1 , BQ_1 , the resultant $R_1 = R$ would still divide AB in C , so that the ratio $CB : CA$ should be equal to $P : Q$, or $P_1 : Q_1$.

If the centre of gravity of a body be fixed, therefore, it will remain in equilibrium however it may be turned around it. This principle, together with the equally simple one, that the resultant of a system of parallel forces is the same as that of the resultants of any groups of forces into which the original system may be divided, suffices for the determination of the centre of gravity of any body whatever. In fact, if m_1, m_2, m_3 &c. be the masses (proportional to the weights) of a number of material particles whose distances from any plane are x_1, x_2, x_3 &c., then the distance \bar{x} of their centre of gravity from the same plane will satisfy the condition

$x(m_1 + m_2 + \dots) = (m_1 x_1 + m_2 x_2 + \dots)$, or as it is usually written $x\sum m = \sum mx$. The sum $\sum m$ represents, of course, the total mass of the system which, as well as $\sum mx$, will in the case of a body be represented by a triple definite integral. The whole theory of the centre of gravity being contained in the above equation, and fully developed in every good

treatise on mechanics, it will be sufficient to notice here a few of the most remarkable properties. When a homogeneous body possesses a geometrical centre, the latter is always its centre of gravity. The centre of gravity may of course fall outside the body. Thus the centre of gravity of a thin homogeneous wire bent in the form of a circular arc is in the radius drawn to the middle of the arc, and its distance from the centre of the circle is to the radius as the chord of the arc is to the length of the latter. The centre of gravity of a plane homogeneous triangular thin plate is the common intersection of the three lines which join each angle to the middle of the opposite side. Mechanically the centre of gravity of any thin plate whatever may be found by suspending it successively from any two points, and, after equilibrium has established itself, drawing, by means of a plumb-line, the vertical through the point of suspension. The intersection of the two lines so drawn will be the centre of gravity. The centre of gravity of a homogeneous triangular pyramid is in the line which joins the vertex with the centre of gravity of the base, and has an altitude equal to three-fourths of that of the pyramid. Amongst the most important *general* properties of the centre of gravity, the following deserve notice. If the mass of each particle of a system, invariable in form, be multiplied by the square of its distance from a given point, the sum of the product will be a minimum when the point coincides with the centre of gravity; it will be invariable for all points equidistant from the centre of gravity, and it will exceed the minimum sum by the product of the total mass into the distance of the point from the centre of gravity. Further, the sum of the products of every two masses and the squared distance between them is equal to the above minimum sum multiplied by the total mass. (Lagrange, *Mécanique Analytique*.) If a number of forces in equilibrium around a point be represented in direction and magnitude by right lines from that point, the latter will be the centre of gravity of equal masses, situated at the other extremities of these lines.

Many geometrical applications of the properties of the centre of gravity have been made. [BARYCENTRIC CALCULUS and GULDIN'S THEOREM.] The centre of gravity of a number of mathematical points, considered as representatives of equal masses, is called the *centre of their mean distances*. In the case of n such points whose distances from any plane are x_1, x_2, \dots, x_n , the distance \bar{x} from the same plane of the centre of mean distances will be

$$x = \underline{x_1 + x_2 \dots + x_n}$$

Centre of Gyration. [GYRATION.]

Centre of Oscillation. [OSCILLATION
and PENDULUM.]

Centre of Spherical Curvature. The centre of the osculating sphere of a non-plane curve. It is a point equidistant from four

CENTRES, HARMONIC

consecutive points on the curve, and lies, consequently, in three consecutive normal planes, or two consecutive polar lines; hence it is a point in the cuspidal edge of the polar developable.

Centres, Harmonic. [HARMONIC CENTRES.]

Centres of Principal Curvature. The centres of curvature of the two normal sections at any point of a surface. They coincide with the only two points in which the normal is intersected by consecutive normals. The locus of the centres of principal curvature, usually called the *surface of centres*, consists of two sheets to each of which every normal of the original surface is a tangent. The properties of this surface were investigated by Monge (*Application de l'Analyse à la Géométrie*), and have since been studied by various other authors. The excellent treatise on Surfaces by Dr. Salmon may be consulted on the subject with advantage.

Centrifugal and Centripetal Forces.

These are usually defined as the forces which urge a body to avoid (fugere) or seek (petere) a centre. Owing, however, to a prevalent vagueness in the use of these terms, it will be well to illustrate their meaning in one special case. Suppose a body to rotate with a constant angular velocity around a fixed axis,

then every point A will describe a circle ABA, in a plane perpendicular to that axis, of which the centre O will be a point in the axis itself. If perfectly free, the point A would describe the right line

AC tangential to the circle; but not being permitted to do so, it exerts a certain constant strain in the direction of the radius OA, which strain calls forth an equal resisting force. The strain in this case is called the *centrifugal* force, the force of resistance the *centripetal*. To measure the latter, and therefore also the former, it is only necessary to consider the space AD through which the body has been urged by it during the time-element required for the description of the elementary arc AB. Calling F the accelerating centripetal or centrifugal force, we have on the one hand [ACCELERATION] $F = \frac{2AD}{t^2}$, and on the

other, by geometry, $AD = \frac{AB^2}{AA_1} = \frac{AB^2}{2r}$ where

r is the radius of the circle; consequently

$$F = \frac{1}{t^2} \frac{AB^2}{r} = \frac{V^2}{r},$$

V being the velocity with which A moves in the circle. Hence the centrifugal force in a given circle is directly proportional to the square of the velocity.

If the time in which a complete rotation is made be represented by τ , then $V = \frac{2\pi r}{\tau}$ and

CENTRIFUGAL MACHINE

$F = \frac{4\pi^2 r}{\tau^2}$; that is to say, the angular-velocity

being the same, the centrifugal forces in two wheels are proportional to their radii. Thus, considering the earth as a sphere of radius R, the radius of the circle described by a body at a point whose latitude is λ will be $R \cos \lambda$, and F and f being the centrifugal forces at the equator and at the point in question, we have $f = F \cos \lambda$. If moreover f be resolved into two components, one horizontal and the other vertical, the latter will have the magnitude $f \cos \lambda = F \cos^2 \lambda$, will be directly opposed to gravity, and thus tend to diminish the weight of the body. At the equator the diminution of gravity owing to centrifugal force amounts to $\frac{1}{336}$ th of what gravity would be were there no rotation; so that if the earth rotated with $17 = \sqrt{289}$ times its present velocity, bodies at the equator would have no weight whatever. The above result may also be expressed by saying that the force of gravity at the poles, where there is no centrifugal force, exceeds that at the equator by $\frac{1}{336}$ th of the former. This is on the assumption that the earth is a homogeneous sphere; its actual form, however, is that of an oblate spheroid, in consequence of which the force of gravity at the poles is still further increased: the above ratio augmented to about $\frac{1}{350}$ th.

By the term Centrifugal Force as applied to a body describing any curve in space, is usually understood the force in virtue of which it is deflected from a rectilinear path. At the instant under consideration we may in fact conceive the body to be moving in the circle which osculates its actual trajectory, so that if ρ denote the principal radius of curvature of the latter and v the velocity of the body, $\frac{v^2}{\rho}$ will

be the expression for the centrifugal force.

Centrifugal Machine. A machine moved by the centrifugal force of water; frequently called, from its inventor, *Barker's Mill*. It consists of a hollow metal cylinder or pipe of metal placed upright, and resting on a pointed steel pivot at A. The pipe is widened or extended into a funnel shape at the top B, and is kept in its position by a vertical steel axis CD, passing through a frame at the top. Towards the lower extremity, two or more small pipes AE, AF, with closed external ends, are inserted at right angles to the axis. In the side of each of these an orifice is made as near as possible to the end, and on opposite sides, so that water from them may spout horizontally in opposite directions. Water is conveyed into the funnel at the top, through the pipe G, in such quantities that the tube is kept constantly full, while the discharge is going on at the orifice near the extremities of the horizontal pipes. In this state of things the resistance or reaction generated by the water issuing from

CENTRIPETAL

the side holes is such as to throw the vertical pipe, with its arms and axis, into rapid rotary motion; and this axis may communicate its motion or power to wheel-work or machinery, or to a millstone connected with its upper end. (*Library of Useful Knowledge*, 'Treatise on Hydraulics'; *Ferguson's Lectures*, by Brewster; Lardner's *Cabinet Cyclopaedia*, 'Hydrostatics and Pneumatics'.) A machine of the same construction, but having the arms at the upper end, and turned rapidly by means of a wheel and pinion, was invented by Mr. Erskine for raising water. Centrifugal Machine is also used synonymously with *Whirling Machine*, an apparatus for the extraction of water from moist substances by centrifugal action. This machine is sometimes called a hydro-extractor.

Centripetal (Lat. *centrum*, and *peto*, *I seek*). In Botany, a term employed in describing the inflorescence of plants, when, in the unfolding of a head of flowers, those at the circumference open first, and those in the centre last. It is also used by carpologists in describing seeds when the apex of an embryo is directed towards the centre of a fruit.

Centriscaus (Gr. *κέντροσκος*). A genus of Acanthopterygious fishes, having the foremost dorsal placed far backwards, and with its first spine remarkable for its length and strength; the mouth is slender and elongated, whence they have obtained the name of 'sea-snipes.'

Centrum (Lat.; Gr. *κέντρος*, *centre*). A term applied by Fries technically to designate the typical division of the groups of species and genera, in his circular arrangement of *Fungi*. Many generic names are compounded, having this word for their root, as *Centrogaster*, *Centrolophus*, *Centropistis*, and *Centronotus*, all genera of spiny-finned fishes; *Centropus*, a genus of birds, allied to the Cuckoos, &c.

Centumviri (Lat.). In Roman History, judges chosen three from each of the thirty-five tribes, so that properly there were 105; but they were called *centumviri*, or the hundred, from the round number. The origin and powers of this court are subjects involved in great obscurity. The principal causes that came under them appear to have been those concerning testaments and inheritances.

Centuriators of Magdeburg. A name assumed by certain Lutheran writers, who, in the middle of the sixteenth century, compiled at Magdeburg a complete history of the Church from the earliest times down to the Reformation. This is the greatest work on ecclesiastical history written on the Protestant side. (Hallam's *Literary History*, part ii. chap. ii.)

Centuries (Lat. *centurie*). In Roman History, the divisions in which the people voted at the *Comitia Centuriata*. According to the testimony of Livy, they were instituted by Servius Tullius for the purpose of giving to the rich a greater weight in the state. The patricians were represented by six centuries of knights, and twelve centuries of knights were added to these from the plebeians. The rest

CEPHALODIUM

of the plebeians and clients were divided into five classes, according to the amount of their property; the lower limits of each being respectively 100,000, 75,000, 50,000, 25,000, 12,500 asses. The first of these classes was subdivided into eighty centuries; the next three into twenty each; and the last into thirty. The centuries of each class were again separated into two equal numbers of old and young. By this distribution the preponderance was given to property, though the rich classes were of course outnumbered by the poorer. On the contradictions in the accounts given of the institution of the centuries, see Sir G. C. Lewis, *On the Credibility of Early Roman History*, i. 493 &c.

In the Roman legion, the name Century was applied to the half of the manipulus, or one-thirtieth of a legion.

Centurion (Lat. *centurio*). An officer in the Roman army, who had the command of a Century [which see]. The word Centurion signifies the commander of 100 men; but this number was in fact seldom complete, as the legion generally fell far short of its full complement. One of the two centuries of each manipulus had a precedence before the other; and the centurion of the first century of the first manipulus of the Triarians presided over all the others, and had the charge of the eagle or chief standard of the legion, which gave him the privilege of ranking with the knights. The badge of a centurion was a vine rod.

Cephaelis (Gr. *κεφαλή*, *a head*). A genus of *Cinchonaceae*, with the flowers collected in heads surrounded by a leafy involucre, a funnel-shaped corolla, enclosed anthers, and succulent fruit having two compartments, each containing a single seed. *C. Ipecacuanha* is the plant which produces true Ipecacuanha, the emetic properties of which are due to a principle called metin.

Cephalanthium (Gr. *κεφαλή*, *the head*, and *άνθος*, *a flower*). A term invented by Richard to express the head or capitate inflorescence of composite plant.

Cephalaspis (Gr. *κεφαλή*, *head*, and *ἀσπίς*, *buckler*). A genus of Placogonoid heterocercal fishes of the Devonian period in which the posterior angles of the shield-shaped helmet that covered the head were produced backwards in a pointed form, giving to the head the appearance of a saddler's knife.

Cephalic (Gr. *κεφαλικά*, from *κεφαλή*, *the head*). Medicines used for the relief of diseases of the head are frequently termed *cephalic remedies*.

Cephalitis. Inflammation of the brain.

Cephalium (Gr. *κεφαλή*). The peculiar woolly mass formed at the apex of the stem of *Melocactus*, out of which the flowers issue.

Cephalo-thorax (Gr. *κεφαλή*, *the head*, and *θώραξ*, *the chest*). The first segment of Arachnidans and Crustaceans, which includes the head and thorax of insects.

Cephalodium (Gr. *κεφαλή*). In Botany, a term used by systematic writers on lichens,

CEPHALOPHORA

and signifying the figure of a convex shield without an elevated rim; it is called also a tuberculum.

Cephalophora (Gr. κεφαλή, *the head*, and φέρω, *I bear*). A name substituted by De Blainville in his system of Malacology for the 'Cephalopoda' of Cuvier.

Cephalopods or **Cephalopoda** (Gr. κεφαλή, *the head*, and πούς, *the foot*). A class of Molluscous animals having the head situated between the body and the feet; these latter organs consist of a number of fleshy processes, which project forwards from the circumference of the head, and more or less conceal the mouth. The Cephalopods are the first class of *Mollusca* in the system of Cuvier, and the most highly organised of invertebrate animals. They alone present indubitable rudiments of an internal skeleton, developed for the purpose of protecting a brain and lodging organs sight, and, in most of the existing species, organs of hearing. In these also there are distinct hearts both for the systemic and pulmonary circulations; and highly complicated digestive, secretory, respiratory, and generative organs. The sexes are in distinct individuals. All the species are marine. The principal features of the organisation of this class of Invertebrata are described by Aristotle, and their habits were better understood by that ancient author than by modern naturalists of the present day. The Cephalopods are described and grouped together in the *Historia Animalium*, under the name of 'Malakia.'

Cephalotese (Cephalotus, the only genus). A small natural order of Exogens, allied, according to Labillardière, to *Rosaceæ*, according to Brown to *Francoaceæ* and *Crassulaceæ*. Lindley places it in his RanaI alliance, regarding it as a transition to *Francoaceæ* in the Berberal alliance. It consists of a single species, a marsh plant inhabiting New Holland, having pitcher-like bodies mixed with its leaves.

Cepheus (Gr. Κηφείus). One of the ancient northern constellations, which takes its name from Cepheus, king of Ethiopia, husband of Cassiopeia, and father of Andromeda. It is surrounded by Cassiopeia, Ursa Minor, Draco and Cygnus, and comes on the meridian at midnight in the middle of August.

Cepola (derivation unknown). The name of a genus of spiny-finned fishes, including the common riband-fish (*Cepola rubescens*) of our coasts.

Ceraceus (Lat. cera, *wax*). In Botany, waxy. Applied to the substance of such bodies as have the texture and colour of new wax, as the pollen masses of particular kinds of *Orchis*.

Ceradia (Gr. κέρας, *a horn*). A genus of *Compositæ*, the only species of which is a dwarf fleshy forked stemmed plant, *C. furcata*, found on the island of Ichaboe and the west coast of Africa. The wounded stems exude tears of a gum resin, which has an odour resembling myrrh, and has been called African Bdellium.

CERATIUM

Cerambycidae (Gr. κεράμβυς). A family of Capricorn beetles, characterised by antennæ generally exceeding the length of the body; - large and distinct labium; strong horny mandibles; maxillæ terminated by two distinct hairy lobes; eyes kidney-shaped, with the antennæ situated in the concavity; body generally long and narrow. The numerous insects of this vegetable-feeding family are arranged in many sub-genera, of which the following are indigenous: *Acanthocinus*, *Aphelocnemia*, *Callidium*, *Cerambyx*, *Clytus*, *Lamia*, *Molorchus*, *Monochamus*, *Obrivum*, *Pogonocherus*, *Saperda*, and *Stenopterus*. One of the most remarkable species of our country is the musk-beetle (*Cerambyx moschatus* of Linnæus, *Callichroma* of Latreille), which, when alive, sometimes disseminates an odour resembling that of the otto of roses.

Ceramics (Gr. κεραμικός, from κέρανος, *potter's earth*). A word used in the Arts to express all the varieties of the Potter's trade which have been burnt or roasted in a kiln. These productions are of great beauty and delicacy, and they often display the highest talent of the artist.

Cerasin (Lat. cerasus, Gr. κέρας, *the cherry*). Cherry-tree gum. A generic name given to those kinds of gum which swell and soften, but do not readily dissolve in water.

Cerastes (Gr. κέραστρος, *horned*). The name of a genus of poisonous serpents, characterised by having a pointed recurved horny process standing up over each eye: the horned vipers, as they are termed, are peculiar to Africa.

Cerasus (Lat.; Gr. κέρας, *cherry-tree*). The genus of *Drupaceæ* (or *Rosaceæ*) which contains the Cherry. Wild cherries are of two kinds, *C. avium* and *C. vulgaris*, and from one or other of those all the fine cherries of our gardens and orchards have been obtained. The genus also contains *C. Padus*, the Bird Cherry; *C. Mahaleb*, of the warmer parts of Europe, whose flowers and leaves are used by perfumers; *C. virginiana*, an American febrifuge; and *C. capricida*, a Nepal species which derives its name from its fatal effects on goats. It is the presence of a minute quantity of hydrocyanic acid which renders so many of these fruits useful for flavouring liqueurs. Both the common Laurel of the gardens and the Portugal Laurel are species of *Cerasus*, the former being called *C. Lauro-cerasus* and the latter *C. lusitanica*.

Cerate (Gr. κηρός, Lat. cera, *wax*). An ointment generally compounded of wax and oil or spermaceti.

Ceratium (Gr. κεράτιον, dim. of κέρας, *a horn*). A one-celled, many-seeded, superior near fruit, dehiscent by two valves separating from the replum, the seeds attached to two pongy placentæ adhering to the replum, and alternate with the lobes of the stigma. It differs from the silique or silique in the lobes of the stigma being alternate with the placentæ, not opposite.

CERATONIA

Ceratonia. The Carob-tree, or Algaroba, is the *C. Siliqua* of botanists, a small tree of the Leguminous family remarkable for having no corolla to its flower, but a five-parted calyx, five stamens, and a pistil with a sessile stigma. It grows in the countries bordering on the Mediterranean, and its flat pods are called St. John's Bread or Locust-pods, from an assumption that they formed the food of St. John the Baptist in the wilderness. They contain mucilage and saccharine matter, and are used for feeding cattle, for which purpose they have been of late years imported into this country.

Ceratophyllaceæ (Ceratophyllum, the only genus). A small natural order of Exogens, which has been variously referred to *Conifera*, to *Haloragaceæ*, and to *Naiadaceæ*. Its affinity, however, appears to be greatest with *Urticaceæ*, of which it may be regarded as a degeneration, having the same incomplete unisexual flowers, monocarpellary ovaries, and solitary ovules, but differing in having an inferior radicle and no albumen. The order consists but of one genus, which is found in the ditches of Europe, being constantly submerged, and floating with its long green leaves after the manner of a *Conferua*. The embryo is decidedly dicotyledonous: otherwise the plant might be referred to *Naiadaceæ*.

Ceratophytes (Gr. *κέρας*, a horn, and *φυτόν*, plant). A name applied by Cuvier to a family of Corticiferous Polyps, comprehending those in which the internal axis resembles horn or wood.

Cerberus (Gr. *Κέρβερος*). In Mythology, the many-headed dog which guards the entrance of the kingdom of Hades and Persephonë—the fellow-monster being called Orthros. The names of these dogs appear in the Vedic poems under the forms Sarvara and Vritra, the two dogs of Yama.

Cercariæ (Gr. *κέρας*, a tail). A family of Infusoria, having an enlarged body with a slender tail-like appendage. The body of the true *Cercariæ* of vegetable infusores is rounded; that of the zoosperms or animalcules of the seminal secretion is flattened. [ZOOSPERMES.]

Cercopithecæ. [CICADELLANS.]

Cercopitheus (Gr. *κερκοπιθηκος*). The name of the genus of Quadrumanes, including those which have long tails, but not prehensile; or the 'monkeys' of the Old World.

Cere (Lat. *cera*, wax). In Ornithology, the naked and generally coloured skin which covers the base of the bill in some birds, as in those of the hawk tribe. [FALCONIDÆ.]

Cereal Grasses (Lat. *ceres*, corn). Grasses which produce the bread corns; such as wheat, rye, barley, oats, maize, rice, and millet.

Cerebellum (Lat., dim. of cerebrum, the brain). The lobe of the brain is so called which is the posterior of the medullary masses composing the brain in vertebrata and underlying the great cerebral mass; its functions have been identified by the majority of physiologists as the seat of coördination of muscular action. As Schiff and Schröder van der Kolk have shown that individuals wanting a cerebellum possess the faculty of coördinating their muscular

CEREMONIAL

movements, the doctrine which assigns the muscular centre to the cerebellum may be considered to be disproved, whilst its exact function is yet unknown. Gall described it as the seat of the sexual instinct (amativeness). The opinions, however, of Lockhart Clarke, and the experiments of Combette and Lewes, tend rather to the doctrine that it also possesses a share in sensation, and may possibly even participate in the production of mental phenomena. [BRAIN.]

Cerebral Lobes (cerebrum, the brain). The surface of the cerebrum in man is divided into three divisions, the anterior, middle, and posterior lobes. The two first are separated from each other by the Sylvian fissure. Between the middle and posterior lobes, however, no definite line of demarcation exists. The third lobe in man covers the posterior third of the cerebellum, and extends beyond it. In the inferior Mammalia, the posterior third of the cerebellum (at least) is left uncovered, a character differentiating all other animals from man. The cerebral lobes are connected together in the subclasses, *Archencephala*, *Gyrencephala*, and *Lisencephala*, by the structure termed *corpus callosum*, which is functionally absent in the marsupial Mammalia. The lobes are covered by *gyri* or convolutions, which are most numerous and least symmetrical in the brains nearest allied to the human race. [BRAIN.]

Cerebric Acid (Lat. cerebrum, the brain). A fatty acid, containing nitrogen and phosphorus, forming one of the components of brain.

Cerebrum (Lat.). The third medullary mass of the brain, counting from behind forwards: it is divided in the mesial line into two lateral lobes or hemispheres, and is the only part of the cerebral organ whose development bears relation to the intelligence of the species. [BRAIN.]

Ceremonial of European Powers.

Comprises—1. The particular titles due to sovereigns in different states; the imperial title being considered as expressing some sort of superiority over the royal, and having been in consequence assumed by various kings in their public acts (as the king of England since the union of the crowns). 2. The acknowledgment of sovereign titles, the right to confer which was formerly claimed by the popes as their own prerogative, but which are now assumed by princes, and confirmed by the acknowledgment of other sovereigns. 3. The respective prerogatives of different sovereigns; which species of precedence is that which has occasioned the greatest amount of discussion and dispute when sovereigns, or their representatives, have been brought together. In 1604, Pope Julius II. arranged the rank of European powers in the following order: 1. The Roman emperor; 2. The king of Rome; 3. France; 4. Castile; 5. Aragon; 6. Portugal; 7. England; 8. Sicily; 9. Scotland; 10. Hungary; 11. Navarre; 12. Cyprus; 13. Bohemia; 14. Poland; 15. Denmark; 16. Republic of Venice; 17. Duke of Brittany; 18. Burgundy; 19.

CEREMONIES, MASTER OF THE

Elector of Bavaria; 20. Saxony; 21. Brandenburg; 22. Archduke of Austria; 23. Duke of Savoy; 24. Grand duke of Florence; 25. Duke of Milan; 26. Elector of Bavaria; 27. Duke of Lorraine: This arrangement, however, gave birth to repeated contests. At present, where precedence is not considered as established between rulers of equal dignity, each concedes to the other precedence at home; and when they meet on the territory of a third party, they take precedence alternately until some arrangement is effected.

Ceremonies, Master of the. An officer of the king's household instituted by James I. for the more honourable reception of ambassadors and strangers of quality. It is his duty to attend and regulate all matters of etiquette in the drawing-room and the levée, and on all occasions where the state of a court is to be maintained.

Cereolite. The name formerly given to Cerolite, and more particularly to the variety found in a violet-red lava in the neighbourhood of Lisbon, where it occurs in rounded grains of a greenish yellow colour.

Cereopsis. The generic name of an Australian goose, characterised by a green cere-like naked membrane covering the upper parts of the base of the bill. It has bred frequently in this country, and there is every probability that it will ultimately become naturalised.

Ceres (Lat.). In Astronomy, one of the four new or telescopic planets which revolve between the orbits of Mars and Jupiter. It was discovered by Piazzi on the 1st of January, 1801. Ceres is a very small planet, its apparent diameter, according to Schroeter, being only 3'48", which at its mean distance corresponds to about 1,600 miles; but according to Sir W. Herschell its apparent diameter is only 0'35", or 160 miles. The difficulty of distinguishing its real disc, on account of the nebulousity by which it is surrounded, accounts for the discrepancy. Its mean distance from the sun is about two and three-fourths times the distance of the sun from the earth. [PLANET.]

CERES. In Latin Mythology, the goddess corresponding to the Greek DEMETER [which see].

Cereus (Lat. *waxen*). A large genus of *Cactaceæ*, containing many species of great beauty. *C. giganteus*, a native of the hot arid deserts of New Mexico, grows from fifty to sixty feet high, imparting a singular aspect to the scenery of the country, the tall sparingly branched stems looking like telegraphic posts for signalling from point to point of the rocky mountains which are its home.

Cerin (Lat. *cera, wax*). The portion of wax which dissolves in boiling alcohol. Also a peculiar waxy substance obtained by boiling grained cork in alcohol.

Cerine. The name given by Berzelius to a kind of Allanite which is found crystallised and also in crystalline masses of a brownish-black colour, at Bastnäs in Sweden, associated with Cerite, Hornblende, and Copper Pyrites.

CEROSTROTUM

Cerinite (Gr. *κηρός, wax*; from its wax-like appearance). A mineral forming the coating or outer portion of a reniform nodule, about half as large as a fist, embedded in crystalline trap-rock near Black Rock in the bay of Fundy, Nova Scotia. [CENTRALLASITE; CYANOLITE.]

Cerinthians. In Ecclesiastical History, followers of Cerinthus, a heretic of the first or second century, who embraced certain Gnostic views respecting the natures and relations of God the Father and Son. He conceived the supreme God to be the father or originator both of the Deity from whom proceeded the Old Testament, and of Christ; that the God of the Jews was also the creator of this world; and that his dominion over it was superseded by the mission of Christ, who was a son of the supreme Deity residing in a human body. [GNOSTICS.]

Cerinus (Lat. *cera, wax*). In Botany, waxy yellow; a term used in describing colour, to denote a dull yellow with a slight mixture of reddish brown.

Cerio. A term used by Murleel to denote the fruit called a CARYOPSIS [which see].

Cerite. A hydrated disilicate of cerium found in Gneiss, at the copper-mine of Bastnäs, near Riddarhyttan in Sweden. It occurs in short six-sided prisms, also massive and granular, of a colour between dark peach-red and clove-brown, passing into grey; is slightly translucent at the edges, and has a dull adamantine or resinous lustre. It contains also Lanthanum and Didymium [LANTHANOCERITE], and generally a small quantity of Yttria.

Cerium. A metal named after the planet Ceres, and discovered in 1803 by Hisinger and Berzelius in a Swedish mineral termed *cerite*, and since found by Dr. Thomson in *Allanite*, a mineral from Greenland. It is said to be a white brittle metal, very difficult of fusion, and volatile when intensely heated; but we are scarcely acquainted with it in its metallic state. Its equivalent number appears to be 46, on the hydrogen scale.

Cerolein. A soft fat contained in bees-wax.

Cerolite. [KEROLITE.]

Ceroma (Gr. *κήρυμα*). In ancient Architecture, the place where wrestlers were anointed with a mixture of oil and wax.

Ceroplastie (Gr. *κηροπλαστικός, relating to wax-modelling*). The art of modelling in wax; one of very high antiquity. From the testimony of Pliny we learn that Lysistratus, the brother of Lysippus, was the first that used wax for modelling the human figure. He lived in the time of Alexander the Great, and was a native of Sicily.

Cerosin (Lat. *cera, wax*). A waxy substance which exudes from the sugar-cane.

Cerostrotum or **Cestrotum** (Gr. *κερσοστρωτος, inlaid with horn*). A species of encaustic painting chiefly on horn or ivory, with a particular sort of stylum called a **Cestraum** [which see]. Doors were sometimes ornamented

CEROTENE

with this kind of painting, which seems to have resembled very closely the pyrographic process of the present day with the exception of rubbing in the wax.

Cerotene. A white paraffin-like substance occurring in the distillate of Chinese wax.

Cerotic Acid. A constituent of bees-wax.

Ceroxyton (Gr. *κρότος*, *wax*, and *ξύλον*, *wood*). A genus of Palms, one of which, *C. andicola*, is the Wax-Palm of New Grenada. It has a tall stout trunk, bearing a crown of pinnate leaves. The trunk is covered with a thin coating of a whitish waxy substance, highly inflammable, which is collected by cutting down the tree and scraping it. According to Vauquelin, it consists of two parts of resin to one of wax. The wood is hard, and commonly employed for building purposes, and the leaves for thatch.

Certhia (Lat.; Gr. *κέρτιος*). A genus of Anisodactyle or uneven-toed Tenuirostral or slender-billed Passerine birds, commonly known by the name of Creepers. The common tree-creeper (*Certhia familiaris*, Linn.) is a well-known native species.

Certiorari (Lat.). In Law, is an original writ issuing out of Chancery or the King's Bench, directed to the judges or officers of inferior courts, commanding them to *certify* or return the records of a cause depending before them. By this writ indictments and many other proceedings may be removed from any inferior court of jurisdiction into the King's Bench. It lies generally in all judicial proceedings in which a writ of error does not lie; but not, in common cases, to remove a cause out of an inferior court after verdict.

Cerulina. Indigo which has been dissolved in sulphuric acid.

Cerumen. The secretion which lines the external auditory canal. It consists of albumen, an oily matter, and a bitter colouring matter.

Ceruse, Cerussite or Cerussite (Fr. *ceruse*; Lat. *cerussa*, *white-lead*). Native carbonate of lead, or white lead-ore. When pure it consists of 16.42 per cent. of carbonic acid and 83.58 oxide of lead; corresponding to 77 per cent. of metallic lead.

It occurs in fibrous, compact, and earthy masses and in numerous crystalline forms which may be referred to a right rhombic prism; also in macles and pseudomorphous forms. When perfectly pure it is colourless and transparent, with an adamantine lustre, which is resinous on fractured surfaces; sometimes the colour passes into grey and greyish-black or it is tinged blue or green by salts of copper. It is very tender and brittle, breaking with a small conchoidal fracture, and is highly double-refractive.

Next to Galena, Cerussite is the most common ore of lead, but it is not often found in sufficient quantity to be of equal importance to the miner. It is of frequent occurrence in lodes, sometimes also in beds in sedimentary limestone, and is almost always associated with Galena, from which it has in most cases ori-

CESTRUM

ginated (Bischof). It is found in Cornwall, Devonshire, Cumberland, Derbyshire, Shropshire, Cardiganshire, Scotland, Ireland, Siberia, Saxony, Bohemia, the Harz, Silesia, Hungary, Carinthia, Westphalia, Monte Pone in Cagliari, North America, &c.

Under the name of *white-lead*, carbonate of lead forms the basis of white oil-paint.

Cervantite. Native trioxide of antimony, composed of 19.9 per cent. of oxygen, and 80.1 antimony; which occurs in acicular crystals, also massive and as a crust or powder, associated with Grey Antimony-ore, at Cervantes in Spain, and at Pereta in Tuscany. The colour is nearly white, or slightly tinged with yellow, with a greasy, bright, or earthy lustre.

Cervidae. [DEER.]

Cervinus (Lat. from *cervus*, a stag). In Botany, fawn-coloured.

Cervix (Lat.; literally, the lower part of the neck). An obsolete botanical term, superseded by RHIZOMA [which see].

Cessio Bonorum (Lat.). In Civil Law (and in the modern jurisprudence of France, Spain, Holland, and Scotland), a yielding up on the part of an insolvent trader of his estate and effects to creditors, under the authority of the competent court; analogous to the assignment of estate and effects under a fiat in bankruptcy in England. See as to the several regulations respecting the *cessio bonorum* in these different countries, Burge's *Commentaries on Colonial and Foreign Laws* iii. 890 &c.

Cestodeans, Cestodea (Gr. *κεστός*, *embroidered*, and *εἶδος*, *likeness*; *riband-like*). The name of an order of Sterelmintha, or Parenchymatous Entozoa, including those which are commonly called tape-worms.

Cestraceæ (Cestrum, one of the genera). In Botany, a very small group of plants, most usually combined with *Solanaceæ*, but by some botanists separated on account of their straight embryo, foliaceous cotyledons, and valvate corolla. Some of the species have fragrant flowers, especially at night; others emit an unpleasant odour. Some are astringent; others are said to be poisonous.

Cestracion (Gr. *κεστραῖος*). In Ichthyology, a genus of sharks, characterised by having two kinds of teeth, disposed in oblique subspiral rows; those at the anterior part of the jaws are pointed, and adapted for seizing or grappling shell-fish, &c.; those at the middle and back part of the jaws are flattened for crushing the same: the fishes of this genus are also remarkable for the large spine placed in front of the first dorsal fin. Only two existing species of this genus are known, one of which is called 'the Port Jackson shark.' The fossil remains of Cestracions are numerous.

Cestrotum. A picture made with the CESTRUM [which see].

Cestrum or Cestron (Gr. *κεστρον*). An instrument, also called *γγραψις* by the Greeks, used by the ancient painters of Greece and Rome, in drawing and painting; it was pointed at one end and flat at the other, and was therefore

CESTUS

applicable to both drawing and spreading the colour; it was generally made of metal.

There were three kinds of painting in use among the Greeks and Romans: in two ways with the cestrum, and in a third way with the pencil. This last was used chiefly for decorative work; the colour mixed with wax being burnt into the wood by applying a cauterium to the surface: most surface work was probably executed in this way. The ivory painting with the cestrum (*in ebor cestro*) was more drawing than painting, and seems to have been executed with a hot point; and though not wax painting, was nevertheless encaustic. The second method with the cestrum (*cera cestro*), which was that of Pausias and others, was with the wax colours, which were afterwards burnt in. The colours of the ancient painters were commonly called *cera*, as being originally, if not always, mixed with wax.

Cestus. [ATHLETES; GIRDLE.]

Cestvaen, Cistvaen or Kistvaen. A species of stone receptacle often found in barrows (generally at the east end), containing the bodies of the persons buried therein. Cistvaens are commonly formed of three stones, placed on edge, like the three sides of a box, with a stone cover. Some of these monuments, which are styled cistvaens by Sir R. C. Hoare and other antiquaries, are, however, not sepulchral.

Cetaceans, Cetacea (Gr. *κῆτος*, a sea-monster). An order of Mammals living in the sea or large rivers, and shaped like fishes for moving habitually in the watery element, having the posterior part of the spine disencumbered of a sacrum and hinder extremities to allow the tail to have a due freedom and extent of motion. They breathe air, have warm blood, and a double circulation, like the rest of the class to which they belong; they are consequently compelled to resort to the surface for the purpose of respiration; and the tail-fin is accordingly horizontal, and not vertical, as in true fishes.

Cete (Lat.; Gr. *κῆτος*). The name of the sixth order of Mammalia in the *Systema Naturæ* of Linnaeus, containing those marine species which are devoid of hinder extremities. The group corresponds with the carnivorous group of the modern *Cetacea*, the manatee being associated in the Linnaean system with the elephant.

Cetic Acid. The result of the action of alkalis upon *cetine*.

Cetine. Pure spermaceti.

Cetiosaurus (Gr. *κῆτος*, whale, and *σαῦρος*, lizard). A genus of fossil Opisthocoelian Crocodiles, in which the vertebrae exhibit a slightly hollowed cup behind, the forepart being flattened in the dorsal, but produced into a ball in the cervical part of the body. The Cetiosaurians fulfilled the same functions in the Jurassic ages as their analogues the dolphins and whales of the present day.

Cetraria (Lat. *cetra*, a buckler). The genus of lichens which yields Iceland moss. *C. islandica*, the plant to which this name is

CHAILLETIACEÆ

applied, affords a nutritious article of diet, and a doubtful medicine.

Cetrario Acid. *Cetrarine*. A white bitter acid contained in Iceland moss.

Cetus (Gr. *κῆτος*, the whale). One of Ptolemy's forty-eight constellations, in the southern hemisphere.

Cetyl. The radical of a series of organic bodies. The hydrated oxide of cetyl is *ethal*, the base of spermaceti. It combines with negative radicals, forming salts.

Cevadille Acid. An acid contained in the seed of the *sabadilla*.

Cevadilla. [SABADILLA.]

Ceylanite or Ceylonite. An iron-and-magnesia Spinel found in rounded grains or small crystals, which are nearly opaque, and of a dark blue or black colour. It is named after the country, Ceylon, where it was first observed in the sand of the rivers. [PLEONASTE.]

Chabasie, Chabasite or Chabazite (Gr. *χαβδῖος*, the name of a stone, mentioned in a poem ascribed to Orpheus). A zeolitic mineral. It is a hydrated silicate of alumina and lime, with small quantities of soda and magnesia, and occurs crystallised in transparent and colourless or greyish obtuse rhombohedrons, which are sometimes pale-red superficially, in certain basaltic and amygdaloidal rocks, or in the geodes of quartz and agate which are disseminated through them. It is found, in Ireland, at Portrush and the Giant's Causeway [PHACOLITE]; in Scotland, at Glen Farg, Eig, and the islands of Mull and Skye; and in Faroe, Iceland, Greenland, Bohemia, Nova Scotia, &c. [ACADIALITE; HAYDENITE; and PHACOLITE.]

Chacone or Ciacone (Span.). In Music, a kind of dance resembling a 'saraband,' of Moorish origin. The bass of it consists of four notes, which proceed in conjoint degrees, whereon the harmonies are made with the same burden.

Chaff (A.-Sax. *ceaf*). The husk or withered calyx of grasses, and more especially of the bread corns. The term is also applied to straw or hay cut into very short lengths, and used for mixing with corn, roots, or other food for horses or cattle. This kind of chaff, in greater lengths, is also used for mixing with mortar on some parts of the Continent, more particularly in Germany and Russia; and it is used as a substitute for hair in making plaster for rooms. Both stubble and cut hay were used by the ancient Egyptians in making bricks.

Chaff of the Receptacle. A term used by some botanists to denote the bracts stationed upon the receptacle of Composite flowers, between the florets; they have generally a membranous texture, and are usually called *Paleæ*.

Chamneh. [SPIEA.]

Chasy. Paleaceous; when a surface is covered with small, weak, erect membranous scales, resembling the chaff of corn, as the receptacle of many Composite plants.

Chailletaceæ (Chaillietia, one of the genera). A natural order of shrubby arborescent

CHAIN

Erogeneæ, placed by De Candolle between *Homaliaceæ* and *Aquilariceæ*, but referred by Lindley to the *Rhamnall* alliance, in which it is known by its polypetalous flowers, valvate calyx, stamens alternating with the petals, and pendulous seeds. It agrees with *Homaliaceæ* in the presence of glands round the ovary, but differs in its superior ovary, with the placenta in the axis, and in other characters; and appears to have the closest affinity with *Rhamnaceæ*, with which it agrees in habit. It inhabits the hotter parts of the world, and some species are said to be poisonous.

Chain (Fr. *chaîne*, Lat. *catena*). A succession of links, each of which, except the first and the last, joins two others; in buildings, a chain is frequently used with an anchor. The link may be a ring, or a bar of any length with a ring or an eye at each end, or a bar with a hook at one end and an eye at the other; links furnished with eyes are joined by links furnished with hooks, or by keys, pins and wedges. Much depends upon the shape of the links in order to obtain the greatest resistance of a chain; and as long as the strain is kept in the direction of the axis, the strongest form will be obtained when the sides of the chain are parallel to the line of strain. But as this is often in a direction perpendicular to the axis, it is essential to introduce a stay which should maintain the sides invariably in their position, and to resist any unequal compression of the metal in the sides. In the cables used for hoisting building materials, it is not necessary to introduce these stays, because the effort being always one of traction is in the direction of the axis; but in ship cables they are always placed, and they are made of cast iron.

Chain Bond. The name given to a bond course of timber introduced as a part of the construction of masonry, or brickwork, to resist the tendency of those materials to spread laterally under the superincumbent weight.

Chain, Gunter's. The unit of length employed by land surveyors, 100 links = 4 poles = 66 feet = 22 yards. Ten square chains, therefore, are equivalent to an acre. Where land is to be measured for building purposes, a chain 100 feet in length is sometimes used. The object in using such chains is, of course, to facilitate subsequent computations by the introduction of a decimal system.

Chains. On Shipboard, are iron bars or plates bolted strongly through the vessel's sides, and containing in their upper parts the dead-eyes through which the shrouds pass.

Chain-shot. Two cannon-balls connected together by a few links of chain. These balls are used chiefly in Naval warfare. When discharged, they fly apart; and the projectile, revolving necessarily on its shorter axis, mows down any object in the way of the extended chain. The effect upon masts and standing rigging is peculiarly damaging.

Chalaza (Gr. *χάλαζα*, in the sense of *ἀκρόθ*). In Botany, the vascular disc caused by the expansion of the vessels of the raphe, upon

CHALCOPHYLLITE

reaching the base of the nucleus of an ovule, after passing up the side of the latter.

Chalazæ (Gr. *χάλαζα*, *hail*). A name applied to the two membranous twisted chords attached to near the poles of the yolk of an egg, and serving to maintain it in such a position that the cicatrix shall always be uppermost, and consequently nearest the source of heat during the process of incubation.

Chalcedony. A semi-transparent kind of Quartz which has been apparently produced by the infiltration of water holding silicious matters in solution. It occurs stalactitic, mammillated, and botryoidal, of various colours, but usually milk-white. It is often banded with concentric laminae of two or more colours, when it is called *Agate*. The red and yellow varieties are called *Carnelian*, and those of a deep brownish red, *Sard*.

The name is after that of the locality (Chalcedon in Asia Minor) where it is said to have been originally found. Fine specimens of Chalcedony are obtained north of Monte Verdi in Tuscany, from the amygdaloids of Iceland, and the Farøe Islands, also from Saxony, Hungary, India, Arabia, Surinam, and Siberia. In the United Kingdom it is found in Cornwall, Devon, and Cumberland; at the Pentland Hills and other places in Scotland; and in Ireland at the Giant's Causeway and elsewhere. Beautiful chalcedonic pebbles may be picked up on the beach at Brighton, on the coast of Sussex between Worthing and Selsey; and fine specimens of botryoidal and stalactitic forms are found lining cavities in flint at Houghton Chalk-pit, near Arundel, in the same county.

Agate, Carnelian, Cat's Eye, Chrysoprase, Flint, Hornstone, Onyx, Plasma, and Sard, are all varieties of Chalcedony.

Chalcedonyx. A variety of Chalcedony, consisting of alternate stripes of white and grey.

Chalcidicium (Lat.). In ancient Architecture, this term was used by Vitruvius to denote a large building, appertaining to some basilicas, and appropriated to the purpose of administering justice. The name is said to be derived from *Chalcis*, a city in Eubœa.

Chalcodite (Gr. *χαλκώδης*, *like brass*; from its bronze-like lustre). A mineral, chiefly composed of silica, iron, alumina, and small proportions of alkalis. It is of a greenish bronze or brass-yellow colour, and occurs in minute flexible scales, forming crusts coating *Hiematite*, at the Stirling iron-mine near Antwerp, Jefferson county, New York.

Chalcography (Gr. *χαλκός*, and *γράφω*, *write or engrave*). The art of engraving on copper or brass.

Chalcolite (Gr. *χαλκός*, *copper*, and *λίθος*, *stone*). A variety of Uranite, found in the granite of several Cornish mines near Tavistock; and in Saxony, Bohemia, Belgium, &c. It is a hydrated phosphate of uranium, in which copper takes the place of lime.

Chalcophyllite (Gr. *χαλκός*, and *φύλλον*, *leaf*) or **Copper Melica**. A hydrated ar-

CHALCOTRICHITE

senate of copper occurring in green six-sided tabular crystals which are transparent or translucent, and have a vitreous lustre. It is found in Cornwall near Callington and in Gwynnapp, and also in Saxony, Hungary, and the Banat. The name is in allusion to the ease with which the crystals may be divided into lamina.

Chalcotrichite (Gr. χαλκός, *copper*, and τριχί, *hair*). A fibrous variety of Red Copper-ore, which generally occurs in grouped or reticulated capillary crystals of a crimson or cochineal-red colour. It occurs at Rheinbreitenbach, Moldawa, and Nischne Tagilsk in the Ural. [PLUMB COPPER.]

Chaldron (Fr. chaudron, whence also Cauldron). A measure containing 36 bushels, heaped measure.

Challite (Gr. χαλκί, *gravel*, and λίθος, *stone*). A hydrated silicate of alumina, iron, lime, and soda. It is found in irregular veins of a deep reddish-brown or of a flesh-red colour in the amygdaloid rock of the Sandy Brae district in Antrim, and also at Tudree Hill.

Chalk (A.-Sax. ceale; Lat. calx, *lime*). A form of soft limestone. Chalk is generally of a peculiar white colour, singularly pure chemically, but mixed mechanically with silica either in grains, or in the well-known form of *flints*. This rock is widely spread over Europe. It is common in England, where it forms low hills, ranging from the Yorkshire coast to the coast of Hampshire and the Isle of Wight, with branches to the east coast in Norfolk, and also in Surrey, where both the North and South Downs consist of it. Similar beds cross the German Ocean and the Bristol Channel, and extend for some distance in Denmark and France. The northern extension passes eastward into Poland and South Russia, terminating in the Caucasus. The chalk in France hardens towards the south, and passes into a limestone of ordinary character in the South of France, Switzerland, and Italy.

Chalk seems made up entirely of particles derived from organic matter, and resembles very closely the material brought from the bottom of the Atlantic in deep water. So strong is this resemblance, that it may almost be assumed that the deposit of the original mud that has become chalk was the result of similar causes.

Chalk is highly absorbent, retaining one-third of its bulk of water without difficulty. A cubic foot of wet chalk will contain at least two gallons of water. It is thus very easily injured by frost, and therefore ill adapted for external work in our climate as a building material, but it is useful and has been much employed in the interiors of churches, &c. Chalk being a nearly pure carbonate of lime, makes a lime of extreme purity when burnt. [CHALK-LIME.]

The chalk is rich in fossils, containing a few reptilian remains of great interest, many fishes, and numerous shells and corals, radiata and zoophytes, all of which are more or less charac-

CHAMÆLEON

teristic. The fossils of the English chalk have been very carefully described.

Within the chalk, and apparently buried with it, are numerous beds of flint, which is a black and peculiar form of silex. These seem to have been accumulated round organic substances, generally sponges.

Chalk Stones. The concretions formed in the joints of persons who have long suffered from gout were once supposed of a chalky nature, and acquired the above name. They are chiefly composed of uric acid in combination with soda.

Chalk-lime. The lime obtained by the calcination of the upper members of the chalk formation is known amongst builders by the name of chalk-lime, in order to contradistinguish it from the lime obtained from the calcination of the beds of the chalk-marl. The chalk-lime swells very much in slaking; it decrepitates and falls to powder; and is deficient in hydraulic properties; it is a remarkably pure lime—a fact which accounts for its want of hydraulic power, and unless it be mixed with some substance possessing the property of communicating the faculty of hardening to mortars, it will never set when used in large quantities.

Challenge. In Law, an exception to jurors who are returned to serve on a trial. [JURY.]

Chamaeans. In Conchology, the family of Acephalous Lamellibranchiate Mollusca, of which the genus *Chama*, or clam-shells, is the type. The group is characterised among bivalves by having the mantle perforated by three apertures; one for the passage of the foot, another for the respiratory currents, and a third for the escape of the excrements.

Chamaelaucaceae (Chamaelaucium, one of the genera). A small order of epigynous Exogens, belonging to the Myrtal alliance, and indeed sometimes regarded as a tribe of *Myrtaceae*. It is distinguished by having a one-celled ovary, by its few ascending ovules with the embryo fused into a solid mass, and by its dotted leaves and heath-like habit. The order is Australian, and comprises *Genetyllis*, *Verticordia*, *Calytris*, and a few other genera.

Chamæleon, Chameleon (Gr. χαμαιλέον). A genus of Saurian reptiles with small tubercular scales, and the tail and feet organised for clinging to the branches of trees. The chameleons subsist not on air, as poets feign and the uninformed believe, but on flies and other insects, which are caught by means of a remarkably long and extensible tongue, terminated by a finger-shaped process like the elephant's proboscis, and which the chameleon can dart upon its prey with great rapidity. The rete mucosum, or coloured layer of the skin, contains two kinds of pigment, situated in different layers; the deeper-seated layer is of a deep green or violet-red colour, the superficial pigment is of a greyish colour; the deep-seated pigment is contained in branched cavities, and is movable, producing by its partial accumulation and

CHAMÆLEON

varying proportions with the superficial layer the changes of colour for which the chameleon has in all ages been remarkable.

CHAMÆLEON. A constellation near the south pole; it was thus named by Bayer.

Chamæleon Mineral. A compound of manganic acid and potash, which presents a variety of tints when dissolved in water.

Chamserops (Gr. *χαμσέρωψ*). The most northern genus of Palms, one of whose species, *C. humilis*, is found in the southern parts of Europe, as far north as Nice. They have a crown of fan-shaped pleated leaves, on stems which vary from three to thirty feet in height. The Chinese *C. Fortunei* proves to be hardy in this country.

Chamber (Fr. *chambre*, Lat. *camera*). Properly speaking, this word means a room vaulted or arched, but it is now restricted to mean an apartment appropriated to lodging. With the French the word has a much more extended meaning; but with us, beyond what is above stated, almost the only use of it is that of expressing the room in a palace in which the sovereign receives the subject, which is called the presence chamber; it is usually the most magnificent room in a palace.

Chamber of a Gun. Is a cell or cavity at the bottom of the bore to receive the charge of powder. Mortars, howitzers, shell guns, and rifled breech-loaders, are provided with chambers in our service.

Chamberlain (Fr. *chambellan*). A high officer in all European courts. Originally the chamberlain was the keeper of the treasure-chamber (*camera*, in the tenth century); and this meaning of the word is still preserved, in the usages of corporations of London and other places, where the chamberlain is the officer who keeps the money belonging to the municipal body. But, in modern times, the court officer styled chamberlain has the charge of the private apartments of the sovereign or noble to whom he is attached. In England, the lord chamberlain, or king's chamberlain, is one of the three great officers of the royal household. [HOUSEHOLD.] The chaplains, officers of the wardrobe, physicians, tradesmen, artisans, and others retained in the royal service, are in his department, and sworn into office by him. He is commonly one of the highest nobility of the country; in virtue of his situation he precedes dukes. The emblem of office appropriated to the chamberlain in European courts is a gold key, generally suspended from two gold buttons.

The CHAMBERLAIN of the corporation of the city of London is appointed by the liverymen. He decides differences arising between masters and apprentices, and admits on oath persons entitled to the freedom of the city.

The LORD GREAT CHAMBERLAIN OF ENGLAND (not of the household) is the sixth great officer of state. This office belonged for many centuries to the family of De Vere, earls of Oxford; afterward to that of Bertie. In that line it became vested in coheirresses, and is now held jointly by Lord Willoughby d'Ereshy and

CHAMPIGNON

the marquis of Cholmondeley, the former of whom fills the office for the present reign.

Chambre Ardente. In French History, a name given to the tribunal which was instituted by Francis I. for the purpose of trying and burning heretics; and also the extraordinary commissions established under Louis XIV. for the examination of poisoners, and under the regent duke of Orleans for the punishment of public officers charged with certain offences against the revenues, as also of those who were guilty of fraud in the matter of Law's bank.

Chambre des Comptes (Fr. *Chamber of Accounts*). In French History, prior to the Revolution, a great court established for various purposes; as for the registration of edicts, ordinances, letters patent, treaties of peace, &c. The sovereign chambre des comptes was at Paris; there were also inferior courts in ten provincial cities.

Chamfer (Fr. *chanfreine*). The edge of anything originally right-angled cut aslope or on the bevel, so that the plane then formed shall be inclined at less than a right angle to the other planes which it intersects.

Chamfron or Champ-frein (Nor. Fr.). In Plate-armour, plates of steel or pieces of leather, to protect the face of a horse.

Chamoisite. A hydrated silicate of alumina and protoxide of iron, mixed with more or less carbonate of lime, manganese, &c. It is of a dark greenish-grey or blackish colour, and has an earthy appearance with a compact or oolitic structure. It is found in beds of Ammonite-limestone at the mountain of Chamoison, in the Valais.

Chamomile Flowers (Gr. *χαμαίμηλον*, *earth-apple*). The flower-heads of the *Anthemis nobilis*, or common Chamomile. They are used in medicine in consequence of their bitter extract, which is strengthening, and of their essential oil, which is aromatic and stimulant. The double flowers are much less bitter and aromatic than the single.

Champ de Mars (Fr.). In French History, the public assemblies of the Franks, which were held in the open air, and annually in the month of March; whence the name. Under Pepin and some of his successors they were termed Champs de Mai. An extensive open space in Paris, appropriated to various public solemnities, is termed the Champ de Mars; a name which seems also intended to recall the ancient Campus Martius, or public field of Rome.

Champerty (Fr. *champ parti*, from Low Lat. *campus partitus*, *a divided field*). In Law, is a species of maintenance, being a bargain with the plaintiff or defendant in a suit for the 'campi partitio,' or division of the land or thing in dispute between the party, if he prevails at law, and the champertor, on the latter's bearing the expense of the suit. It is a punishable offence both by common law and by statute.

Champignon (Fr.). The name applied by the French to mushrooms in general, but in his country confined to the *Agaricus oreoidea*,

CHAMPION

one of the Fungi, which forms Fairy Rings, and is also one of the most excellent for culinary purposes. It has the great merit of drying admirably.

Champion (from Goth. *Kempe*). One who fights a public combat, or engages to do so, in his own or another man's quarrel. On the issue in a writ of right, trial by battle might formerly be demanded; and in this case [*WAGER OF BATTLE*] each party appeared in the field by his champion. The judicial combat in criminal cases might in some countries, although not in England, be fought by a champion for either of the parties if an ecclesiastic, woman, or child. The office of champion of the crown of England is of great antiquity; the manor of Scrivelaby in Lincolnshire having been held from time immemorial in grand serjeanty, on condition that the lord thereof shall be the king's champion. This manor was long held by the family of Marmion; it passed in the twentieth year of Edward I. to the family of Dymocke, in which it continued until its recent extinction. The champion appeared in Westminster Hall at the coronation, between the courses of the royal banquet, in complete armour; his challenge was proclaimed by the herald, waging battle with any person who should deny or gainsay the title of the king, three times; and the champion threw down his gauntlet. In 1821, at the coronation of George IV., it was decided that this office could be performed by deputy; and Mr. Dymocke being in orders, his place was supplied by his eldest son, Henry Dymocke, who also executed the duty at the coronation of William IV.; but on his decease without male heirs, this ancient office became extinct.

Chance. A term applied to events whose causes are unknown to us. Thus, when a piece of money is tossed up into the air, as no reason can be given why it should fall on one side rather than on the other, it is said to be an even chance which of the sides will turn up. The *Doctrine of Chances* is an important branch of Mathematics. [*PROBABILITY.*]

Chance-medley (a corruption of the French *chaude melle*). In Law, signified originally a casual affray or riot, accompanied with violence, but without deliberation or pre-conceived malice; but is applied at present to a particular kind of homicide, viz. the killing of another in self-defence in a sudden encounter, without *malice prepense*.

Chancel. The choir of a church between the altar and the lattices (Low Lat. *cancelli*) or balustrades that surround it, which only ecclesiastics might enter. This is the strict meaning of the word; but in many cases the chancel extends much further into the church, the original divisions having been removed for the greater accommodation of the congregation.

Chancellor (Lat. *cancellarius*). A high officer in many European states. The cancellarius under the Roman emperors is supposed to have been a notary or scribe, and his title to have been derived from the *cancelli* or railing behind which he sat. In ecclesiastical matters,

CHANCELLOR

every bishop had (and continues to have) his chancellor, the principal judge of his consistory. The chancellor of France began to be an officer of importance under the Frankish kings, especially after the office of referendary had become merged in his, about the ninth century. In 1223 he was made the first minister of the crown, and rank next after the princes of the blood was assigned to him, until the Revolution. The offices of chancellor and keeper of the seals were frequently united. In Germany, the office of arch-chancellor of the empire belonged to the archbishop-elect of Mentz. The archbishop of Cologne was titular arch-chancellor of Italy; the archbishop of Trèves of Gaul.

In England, the office of chancellor is the most ancient as well as the highest of all judicial offices in the kingdom; for though the superior antiquity of his jurisdiction has been questioned, the establishment of the office itself was certainly prior to the institution of any existing court of justice, the name as well as some of the functions, which were borrowed from the '*cancellarii*' of the later Roman emperors, having been introduced into this country within the first three centuries that followed the dissolution of the Western Empire.

In addition to his judicial functions, which are various and extensive, the chancellor is now by virtue of his office privy councillor, and, when a peer, speaker of the House of Lords; over all the members of which, with the exception of the archbishop of Canterbury, he then has precedence in rank. As chief conservator of the peace, he has nomination of all magistrates throughout the kingdom; and he is the patron of all livings of the crown under the value of twenty marks in the king's books. He has also the right of appointment to almost all the offices in the Court of Chancery, and has very great influence over the appointment of the other judges both of common law and equity. He still retains also the title of keeper of the king's conscience, a duty originally incident to his situation in the king's chapel, over the service of which he presided; and this office may perhaps have afforded a ground for that part of his jurisdiction which professes to remedy what is contrary to equity and good conscience. It is further his duty to issue the writs for the convocation of parliament; and all Acts there passed, as well as many records and documents affecting the rights of individuals—as to the latter in order to their validity—are enrolled and kept in chancery, under the immediate care and custody of the Master of the Rolls, himself an officer of that court. The custody of the great seal is the peculiar and essential mark of the chancellor's dignity; and by delivery of that and the proper oaths taken the office is created, with all such of its rights as can be exercised by a chancellor not being a peer.

The jurisdiction of the chancellor is of various sorts. And, first, as to his common law jurisdiction. By this is meant that part of the

CHANCELLOR

chancellor's jurisdiction which is regulated by the same principles, and exercised according to similar forms, with the jurisdiction of the other courts of common law. This is by far the most ancient branch of the chancery judicature, and seems to have been originally incident to the nature of the chancellor's office, whose chief business it once was to advise the sovereign on the subject of grants, charters, and letters patent, and to authenticate them by affixing the great seal after the introduction of that symbol. Out of this naturally arose a jurisdiction in all matters between the crown and its grantees, and the right to repeal or cancel all grants, charters, and letters patent, which should afterwards appear to be contrary to law, or in other respects improperly obtained. In like manner the chancellor had jurisdiction in other matters arising out of commissions under the great seal; such as returns made in pursuance of enquiries under such commissions as to the right of the crown to goods or lands of the subject either by escheat, forfeiture, or any other cause; these were legally called 'offices.'

To the same court also belonged originally, in the time of feudal tenures, jurisdiction in the case of wardship, and some other matters arising out of such tenures between the crown and its tenants in capite; but it should be observed, that as this court had not the power of summoning a jury, it could in no case try an issue of fact. It is called the Court of the Petty Bag, literally from the size of the bag in which its writs are deposited. To the common law department of chancery belongs also the issuing of original writs; that is to say, precepts addressed to the party complained of, stating the nature of the complaint made against him, requiring him to do justice to it, or show cause to the contrary; such writs being originally the first and a necessary step in all causes which were tried before either of the three great courts, or in the 'aula regia' before its division into separate courts.

In this department of his office the chancellor was assisted by officers named Cursitors, whom he was empowered to nominate for that purpose, and upon whom the whole business of devising writs soon devolved. The chancery has hence been called *Officina Brevium*, or workshop of writs; and is, or was, in respect of the necessity of such writs, the foundation or fountain head of all justice; but this necessity, which had in practice long been satisfied by a fiction, has been in terms dispensed with by the 2nd Wm. IV. c. 39. The receptacle in which these writs were kept was called the *Hansper*—literally a basket; and hence the office from which they issued was called the *Hansper Office*.

But by far the most extensive as well as most important branch of the chancellor's jurisdiction is the equitable; indeed, it is that branch alone which is commonly meant by the term Chancery. In this department the lord chancellor had until 1813 only the assistance of the Master of the Rolls; in that year a vice-chancellor was appointed; in 1841 two additional vice-

chancellors were created; and in 1851 two Lords Justices of the Court of Appeal were added. Proceedings in chancery are, in practice, commenced before the Master of the Rolls or a vice-chancellor; from their decrees or orders appeal lies to the Court of Appeal in chancery, consisting of the lords justices and lord chancellor, who may sit together with or apart from them; and the final appeal is to the House of Lords.

The general object and character of this equitable jurisdiction is to supply, in civil matters, the deficiencies of the other courts of justice, whether those deficiencies consist in the imperfections of the machinery of those courts, or in their too rigid adherence to peculiar forms, whereby certain classes of rights become excluded from the benefit of their protection. The origin of this equitable jurisdiction is generally sought for in that remnant of judicial power which is alleged to have been left in that part of the 'aula regia' which was not included in either of its subdivisions [*KING'S BENCH*; *COMMON PLEAS*], and of which residuary part the chancellor was certainly, since the suppression of the office of justiciary, the principal member, and was thus easily enabled to assume whatever judicial power was left undelegated to the other courts. That such remnant of power was adequate to all purposes to which it was moulded, is inferred from the supreme and comprehensive nature of the 'aula regia' itself, which must be supposed to have been invested originally with full power to do complete and perfect justice, and of which the remnant therefore still retained an undefined measure of authority sufficient to supply what should prove, on experience, to be wanting in the other courts. This view of the subject is strengthened by the fact that the Court of Exchequer, which was not a part of the aula regia, but a collateral and equal court, or rather perhaps the aula regia in a different shape, had also its equitable jurisdiction, in cases in which debtors to the crown were concerned, and, by a convenient fiction, in all cases; as if equity were a necessary part of all complete systems of judicature. Possibly also the idea of paramount and universal authority annexed to the right of framing writs in all actions, or, in other words, of devising remedies for every species of wrong, may have laid the foundation in theory for this supplemental code, as it was certainly the discovery of a new writ, or a new application of an old one, which practically enabled the chancellors to carry their equitable views into effect.

This was the writ of *subpœna*: a writ returnable in chancery, and calling upon the person to whom it was directed to appeal there, and answer upon oath the complaint that was made against him. The invention of this writ is attributed to John Waltham, bishop of Salisbury, who was chancellor in the reign of Richard II.; and on the power thereby acquired the equitable jurisdiction of the chancery even now rests.

CHANCELLOR OF A DIOCESE

The usual division of the subjects of equitable jurisdiction is into Trust, Fraud, Accident, Agreement, and Account.

As courts of equity take into their consideration a far greater variety of circumstances than do courts of law, and as evidence of no fact not suggested by the pleadings is admissible, the written pleadings are necessarily more copious and important than they are at law; and there is further this most essential difference, that the pleadings on the part of the defendant, i. e. his answer, are upon oath. With regard to evidence the same general rules prevail in equity as in law, as to the admissibility of proofs, the relevancy of facts, and the competency of witnesses, and even the propriety of the questions that may be put; but the manner of taking evidence is different, for with few exceptions, and those as to very simple facts, evidence in equity is taken either under a commission to examine, or by the official examiners in London, and is produced before the court in a written shape, although by some recent statutes a power, rarely used, has been given to examine witnesses *visd voce*. Where special applications are made during a cause for something to be done in that cause, or, as may sometimes be done, when applications for an order of the court are made without instituting a suit, the evidence adduced is by affidavit. The hearing of such applications, which is either upon written *petition* or by motion upon written notice, constitutes a great part of the business of the court. The court was formerly in the habit of referring matters for investigation by the masters in chancery, but these officials were abolished by a statute passed in 1852 (15 & 16 Vict. c. 80), and the business formerly transacted by them is now conducted in the chambers of the Master of the Rolls and vice-chancellors. The Court of Chancery has also jurisdiction in the guardianship of infants and the management of charities; and the lord chancellor personally has, by special delegation from the crown, jurisdiction in the case of lunatics, which is regulated by statute. [LUNACY.]

The appellate jurisdiction of the chancellor in bankruptcy is stated under BANKRUPTCY.

Chancellor of a Diocese. The keeper of the seals of an archbishop or bishop. This office now includes those of official-principal, whose duty is to hear and decide matters of temporal cognisance determinable in the bishop's court, and vicar-general, who exercises the jurisdiction properly spiritual.

Chancellor of the Exchequer. The highest finance minister of the British government. This office is from its nature necessarily intrusted to a commoner. The chancellor, as an officer of the Court of Exchequer, has precedence above the barons of that court.

Chancellor of a University. The head of the corporate bodies by whom he is elected. He exercises exclusive jurisdiction in all civil actions and suits where a member of the university or privileged person is one of the parties, except in cases where the right to

CHAPEL

freehold is concerned. The duties of the respective chancellors of Oxford and Cambridge are in nearly all cases discharged by a vice-chancellor.

Change of Seed. In Agriculture, the practice of procuring seed produced in a different soil and climate from that in which it is to be grown as a crop; and which is found to be sometimes beneficial, and sometimes injurious, according as the new seed may have been matured in a better or worse climate and soil than those in which it is to be grown.

Channels. In Nautical language, are projecting wooden platforms jutting out from the ship's sides opposite to the masts. They serve to keep the chains and shrouds distant from the ship's side, preventing thereby chafing against the gunwale, and enabling the shrouds to impart a firmer support to the masts.

Chant (Fr. chanter, Lat. cantare, to sing). In Music, an ecclesiastical song usually adapted to the psalms and litanies. There have been several sorts, of which the first, was the Ambrosian, invented by St. Ambrose, bishop of Milan. The Gregorian system of chant, which was introduced by Pope Gregory, is still in use in the Romish church. The chants now generally used in Protestant cathedrals and churches have been in some measure derived from the ancient systems, but are more modern in form, and have the agreeable features of tonality, harmony, and rhythm, which were wanting in the earlier modes.

Chantarelle (Fr.). The name of an esculent fungus, *Cantharellus cibarius*, a common inhabitant of our woods, and highly esteemed on the Continent.

Chantonnette. A meteoric mineral, forming compact black veins and angular-shaped masses in the stone which fell at Chantonney in France.

Chantry. A little chapel, or altar, commonly in some church endowed (before the Reformation) with revenues for the maintenance of a priest to offer masses for the soul of the founder and others; occasionally chantries were, however, distinct buildings. They were dissolved in England by 1 Edward VI. c. 14.

Chapel (Fr. chapelle). In Architecture, a building for religious worship, as in colleges, hospitals, &c. The name is also applied to places of worship subsidiary to parish churches, which are called chapels-of-ease, or belonging to Dissenting congregations. In Roman Catholic cathedrals and churches, those parts of the building which contain the subordinate altars are called chapels. In English cathedrals, the Lady chapel, or chapel of the Virgin Mary, is commonly at the eastern end of the building. In foreign churches the apse containing the altar is frequently surrounded by a number of psidal chapels.

CHAPEL. In Printing, the junction of the workmen in an office for the purpose of promoting and enforcing order and regularity among themselves, the preservation of the materials, the arrangement of the price of any

E E

CHAPLAIN

doubtful work, and the care of the lights. These objects are accomplished by fines.

Moxon, who published his work on printing in 1683, says, 'every *Printing-house* is, by the custom of time out of mind, called a *chapel*.' It is supposed that the term originated from the circumstance of Caxton, on the introduction of the art into England, practising it in a chapel attached to Westminster Abbey.

The president is termed 'the father of the chapel,' and is elected; the workmen are styled 'members of the chapel;' and this association takes cognisance of all offences, real or imaginary, committed within the office, and punishes the offender by inflicting a fine in proportion to the offence. The process of calling a chapel is by giving the father a half-penny and desiring him to summon a chapel, stating to him the object; the father then directs the youngest journeyman to announce to all the members the time when it will be held; when the subject is discussed, and the decision taken by vote.

It is an axiom that the chapel is always right; consequently there is no appeal from its decision, and to dispute this would subject the party to its displeasure. It has various ways of enforcing obedience to its dictates.

Chaplain (Low Lat. *capellanus*). Properly the minister of a chapel. The privilege which the king and nobility enjoy of appointing private chaplains arises from the ancient custom of using domestic chapels for family worship. The limitations under which this privilege may be exercised are set forth in certain statutes of Henry VIII.

Chaplet (Ital. *ciappelletto*). A string of beads used by Roman Catholics to count the number of their prayers; these prayers consist for the most part of Ave Marias, Paternosters, and Credos. The invention of the practice is generally attributed to St. Dominic. [ROSAARY.]

CHAPELET (Fr. *chapelet*). In Architecture, a moulding carved into beads, olives, and the like.

Chapter (Lat. *capitulum*; from *caput*, *head*). The society of canons in a cathedral or collegiate church, of which the dean is the head, which forms the council of the bishop, and in which his election rested before Henry VIII.; from that time the power of the chapter in this particular (in the English church) has become merely nominal. [BISHOP.]

Chapter House. The apartments attached to a collegiate church, or a cathedral, in which the heads of the chapter meet to transact business; they are usually of a very ornamental character, in Gothic or mediæval buildings, as at Salisbury, Wells, Lincoln, &c.

Characeæ (*Chara*, one of the genera). A natural order of Thallogens entirely destitute of a vascular system, and composed almost exclusively of tubes. The order consists of but two or three genera, which inhabit the fresh and brackish waters of most countries, but are more plentiful in those of the temperate zones. They are remarkable for the distinctness with

CHARACTER

which the rotation of their fluids may be seen under the microscope. In the opinion of some Italian writers, the insalubrity of the neighbourhood of Rome is owing to the great quantity of *Chara* which inhabits all the pools, and renders them intolerably offensive. The smell which they emit resembles that of sulphuretted hydrogen.

Character (Gr. *χαρακτήρ*). In the Fine Arts, a distinctive property or mark by which any object is separated from another. In physics as in morals, and also in the fine arts, there are three species of character; Essential, Distinctive or Accidental, and Relative. *Essential character* is that type stamped by Nature on all her works; that great indication observable in the general divisions of the three kingdoms of nature; those distinctions of different classes of beings, of sexes and ages; in short, of all those great external marks which prevent the confusion of one species with another. *Distinctive or accidental character* is that dependent on particular circumstances; on all those varieties of developement which a vast number of visible or invisible causes stamp on the same species, according to the difference of their position; as on individuals of the same species, according to the difference of the elements which modify their forms and the influences which some actions may have upon them. *Relative character* is a more particular indication of certain faculties relative to the different properties with which nature has endowed certain species or individuals, in which may be recognised the purposes to which they are more especially destined.

The arts are and indeed can be but the result of the imitation of nature in all countries, of the nations that inhabit them, and of the individuals of which a nation is composed. Nature influences nations, nations men, and men the arts. These are governed either mediately or immediately by an influence more or less dependent on the great natural causes of climate, government, and education, which constitute the essential character of every country; on secondary and political causes, in which nations differ; and on particular causes, which modify individuals. The arts do but imitate this process: according to the particular spot in which they spring up, their imitation embraces either nature in general or parts of nature; either material forms and the sensible images of things, or the moral affections and intellectual ideas of things; but of whatever kind the imitation be, to whatever object it may be directed, the arts are but the faithful mirrors which reflect in every country the physical and moral qualities of nature, of nations, and of the individuals of which the latter are composed. Before judging, therefore, of the imitation, it becomes necessary to judge of the model; and before we can ascertain in what the character of the arts consists, we must know on what its character depends in nature. We have been thus particular in giving some general notions of character, which must be felt before we can be qualified

CHARACTERS

to judge of the character of the arts in any country. The character peculiar to himself which an artist imparts to his work, and which is called, *subjective* by the Germans, is but a modification of the foregoing principles: that distinctive character called *objective*, which a work of art requires that it may seem proper and suitable to its end, may perhaps be more easily understood.

Characters. In Music, the conventional forms in musical writing and printing used for signs of clefs, notes, rests, &c.

Characteristic of a Cubic. Is the invariable anharmonic ratio of the four tangents which can be drawn to a plane cubic from any one of its own points. Since anharmonic ratios are unaltered by projection, no two cubics can be projections of one another unless they have equal characteristics. A classification of cubics according to the nature, real or imaginary, of their characteristics might obviously be made. When the characteristic has the value -1 , each set of four tangents forms a harmonic pencil, and the cubic has been called a *harmonic cubic*. When the characteristic has for its value one of the imaginary cube roots of unity, the three fundamental anharmonic ratios of each pencil of tangents are equal to one another and the curve is called an *equianharmonic cubic*. (Cremona, *Theoria Geometrica della Curve Piane*, Bologna 1862.) A harmonic cubic is the Hessian of its own Hessian. (Salmon's *Higher Plane Curves*.)

Characteristic of an Envelope. A term introduced into the theory of curved surfaces by Monge (*Application de l'Analyse à la Géométrie*). A surface being regarded as the envelope of another whose form, magnitude, and position vary continuously with the magnitude of a certain parameter, whilst its nature or order remains invariable, the curve in which two immediately successive generating surfaces intersect, and which obviously lies wholly on the envelope, is called the *characteristic* of the latter. Thus if the generating surface be a plane, and its position be allowed to vary continuously, the envelope will be a developable surface whose characteristic is a right line. Again, if the generating surface be a sphere of constant radius whose centre is allowed to describe a given curve in space, the envelope will be a tubular surface whose characteristic is a circle. It is thus obvious that the envelope may be regarded as the locus of its characteristic.

Two consecutive characteristics intersect in points the locus of which forms an *edge of regression* or *cuspidal edge* (*arête de rebroussement*) on the envelope.

If $F(x, y, z, \alpha) = 0$, where α is a variable parameter, be the equation of the generating surface, the next succeeding one will have the equation

$$F(x, y, z, \alpha + d\alpha) = F + \frac{dF}{d\alpha} d\alpha$$

and the one immediately following the latter, the equation

CHARADRIUS

$$+ F \frac{d^2 F}{d\alpha^2} d\alpha + \frac{d^2 F}{d\alpha^2} d\alpha^2 = 0;$$

so that the equations of a characteristic will be

$$= 0, \quad \frac{dF}{d\alpha}$$

and a point on the cuspidal edge of the envelope will satisfy the equations

$$= 0, \quad \frac{dF}{d\alpha} = 0, \quad \frac{d^2 F}{d\alpha^2}$$

The elimination of α , therefore, from the first two of these equations will give the equation of the envelope, and its elimination from all three will lead to the two equations of the cuspidal edge of this envelope. The nature of the envelope will of course depend upon the form of the function F , as well as upon the manner in which the parameter α is involved therein. So long as F remains of the same form with respect to its variables x, y, z , the envelopes are said to belong to the same family, and their equations always satisfy one and the same partial differential equation whose order depends upon the manner in which α is involved in F . The connection between the theory of envelopes and the integration of partial differential equations is at once apparent; for further information on this important subject, however, recourse must be had to the works of Monge; Boole, *Differential Equations*; Salmon, *Analyt. Geom. of Three Dimensions*; and others.

Characteristic of a Logarithm. Denotes the positive or negative integer to which a positive decimal, the mantissa, must be added in order to obtain the logarithm itself. It is only in common or Briggs's logarithms that any great advantage is gained by thus distinguishing between the integral and decimal parts of a logarithm and by keeping the latter always positive. This convention being made, however, tables of logarithms are much simplified and abbreviated; for the logarithms of all numbers which have the same significant digits, that is to say of all numbers which are obtainable from one another by multiplication by a power of ten, will now have the same mantissa, and the characteristics may be supplied so easily that they need not be recorded. [LOGARITHMS.]

Characteristic of a Plane. [KINEMATICS.]

Charade (Fr.). A species of riddle, the subject of which is a name or a word that is proposed for solution from an enigmatical description of its several syllables taken separately as so many individual words, and then from a similar description of the whole name or word. A charade can only be called complete if the different enigmas which it contains are brought into a proper relation to each other, and, as a whole, unite in an epigrammatic point. The word *charade*, like the term CALEMBOURG [which see], has, it is asserted, been applied to this sort of amusement, from the name of its inventor.

Charadrius (Lat.; Gr. *χαράδριος*, from their dwelling in *χαράδραι*, clefts). A bird

CHARCOAL

mentioned by Pliny. The name of a very interesting genus of wading birds, or *Gallinules*, including the British plover and allied species. In modern Ornithology, the Linnæan genus which included the long-legged plover (*Himantopus*), the stone curlew (*Edicnemus*) and other species is raised to the rank of a family called *Charadriade*.

Charcoal. A form of carbon, obtained by burning wood with the imperfect access of air, or by heating or distilling it in iron cylinders so constructed as to allow of the collection of the volatile products; among which are *tar*, and *pyroligneous acid*, which is impure acetic acid. Charcoal, exclusive of its important use as a fuel, is possessed of some curious and valuable properties. It is a very bad conductor of heat and hence powdered charcoal is used to surround tubes and vessels which are required to retain their heat. It is not injured by air, moisture; hence stakes and piles are superficially charred to preserve them. It is infusible; and provided air be carefully excluded, it undergoes no change in most intense heats. It absorbs air and moisture, and also the colouring and odiferous parts of many animal and vegetable substances. Tainted flesh and putrid water are thus sweetened by the action of powdered charcoal, especially by what is called *animal charcoal*, obtained by burning bone, or the clippings of hides, leather, &c. Coloured vegetable solutions filtered through well-burnt charcoal are materially decoloured by it. When burned in oxygen or air, it is converted into *carbonic acid*. [DIAMOND AND CARBON.] Common charcoal intended merely for fuel is prepared by cutting pieces of wood from 1 in. to 3 in. in diameter into lengths of from 1 ft. to 3 ft., forming them into a conical pile, and covering them with turf or clay; leaving two or three holes, close to the ground, for lighting the wood, and boring through the turf in the upper part of the cone a few other holes for the escape of the smoke. The pile being lighted at the several holes along the bottom, continues burning with a slow smouldering flame for a week or two, and is allowed to cool before the turf is removed. In the case of very high winds, the holes to the windward are stopped, to prevent combustion going on with too great rapidity. Charcoal obtained by distilling beech-wood, dogwood, alder, willow, and other woods which are free from resin, is called *cylinder charcoal*. The charcoal employed in the manufacture of gunpowder is now generally so prepared.

Chards. The footstalks and midrib of artichokes, cardoons, and the white beet are so called. In the case of the artichoke and cardoon, the leaves are tied up, and the light excluded by straw ropes or by soil, in order to blanch the chard, and deprive it of its natural bitterness; after which, when dressed, it becomes an agreeable vegetable. The leaves of the white beet, not being naturally bitter, do not require blanching to render them fit for use.

CHARITY, BROTHERS OF

Charge. In Gunnery, signifies the quantity of powder used at one discharge of a gun. For land service there are certain fixed charges for all guns. These are called service charges. They should be such as to give the greatest initial velocity to the projectile, without unduly straining the gun. For heavy and medium smooth-bored guns, the service charge is one-third, for light smooth-bored guns, one-fourth the weight of the projectile. For firing with hot shot and ricochet firing, these charges are reduced. In the navy, three charges are used, viz. distant, full, and reduced. In rifled guns, also, on account of the absence of windage, the longer time the shot remains in the bore, and the greater consequent strain exerted by the gas, the charges are much less. In Armstrong breech-loading guns, they are one-eighth the weight of the projectile.

CHARGE. In Heraldry, signifies the various bearings, i.e. ordinaries and figures, depicted on the escutcheon. A shield is said to be *charged* with the bearings depicted on it; and so is an ordinary or other charge, when it bears another device upon it.

Chargé d'Affaires. The third or lowest class of foreign ministers, according to the regulations adopted at the congress of Vienna.

Charge and Overcharge. In Painting, a term applied to any exaggeration of character, expression from colour, &c.

Charitable Uses. In English Law, purposes of public benefit for which lands might by the indulgence of the law be granted, under certain restrictions, without incurring the illegality of **MORTMAIN** [which see]. Grants for this purpose are now regulated by 24 Vict. c. 9 (1861). The commissioners under whose superintendence the trusts for this purpose are placed were established under the Charitable Trusts Act, 1853.

Charites (Gr. *χάριτες*). In Greek Mythology, the Graces. Homer simply speaks of a *Charis* as the wife of Hephaestus. Hesiod names three, Aglaia, Euphrosynê, and Thalia, the daughters of Zeus and Eurynomê. With the Greeks these beings were the embodiments of gracefulness and beauty. In the ædic mythology, the Harits, with whose name that of the Charites has been identified, are the horses of the sun, glittering with dazzling light. But it would probably be a mistake to suppose that the Greeks borrowed from ædic writings an idea which comes to both Greeks and Hindus from an earlier and common source. The word is traced to the root *har* or *har*, to be fat or glittering; the transition from the idea of fatness to that of brilliance and beauty being shown in a large class of words both in Greek and other languages.

Charity, Brothers and Sisters of. In the Roman Catholic church, orders of 'Hospitallers,' established especially in France. Their office is to attend the sick. The females form a similar society to that of the Beguins in Flanders. [BEGUINS.]

Charles's Wain. A name sometimes given by astronomical writers to the constellation *Ursa Major*, or Great Bear. It has sometimes also been applied to the Little Bear. For the origin of the names of these constellations, see Max Müller, *Lectures on the Science of Language*, 2nd Series, p. 361 &c.

Charlock (also called Kedlock: A.-Sax. cedeleac). A common name for two of our most common agricultural weeds, *Sinapis arvensis* and *Raphanus Raphanistrum*. The plants when young are remarkably like those of mustard or of the common turnip; but they are easily distinguished by the taste, which is hot and bitter, while that of the turnip is mild.

Charon (Gr.). In Mythology, the ferryman who conducted the souls of the departed in a boat across the Stygian lake to receive judgment from Æacus, Rhadamanthus, and Minos, the judges of the infernal regions. He received an obolus from every passenger, for which reason that piece of money was placed in the mouths of the dead.

Charqui. [PRESERVATION OF MEAT.]

Charring of Posts. The practice of carbonising by burning that portion of the surface of wooden posts which is to be inserted in the ground. The object is to prevent the posts from decaying, more especially at the surface of the ground, or, as the common phrase is, between wind and water. The practice is common in most parts of Europe, and even in Russia and Sweden, though timber is there so abundant.

Chart (Lat. charta, paper). A hydrographic map for the use of navigators, being a projection of some part of the sea or coast on a plane surface. Charts as well as ordinary maps may be constructed on any of the principles by which a spherical surface is represented on a plane; Mercator's projection, however, which will be hereafter explained, is the one generally used.

Charta, Magna (Lat.). In English History. The 'Great Charter of the Realm' was signed by King John in 1215, and confirmed by his successor Henry III. It is reported to have been chiefly drawn up by the earl of Pembroke and Stephen Langton, archbishop of Canterbury. Its most important articles are those which provide that no freeman shall be taken or imprisoned or proceeded against, 'except by the lawful judgment of his peers or by the law of the land,' and that no scutage or aid should be imposed in the kingdom (except certain feudal dues from tenants of the crown) unless by the common council of the kingdom. The remaining and greater part of it is directed against abuses of the king's power as feudal superior.

Chartaceous (Lat.). Papery; indicating the paper-like texture and substance of most leaves.

Charte. In French History, originally used to indicate the rights and privileges granted by the French kings to various towns and communities; but applied at present to the

fundamental law of the French monarchy, as established on the restoration of Louis XVIII. in 1814. The *Charte* consists of sixty-nine articles, and is founded on principles analogous to those of the British constitution, as embodied originally in the Magna Charta and subsequently extended in the Bill of Rights. As is well known, it was the violation of an article of the *Charte* by the ministers of Charles X. that led to the revolution of 1830, the expulsion of that monarch from the throne, and the establishment of Louis Philippe's dynasty, which, after eighteen years' sway, was itself expelled, February 24, 1848, and therewith the *Charte* which it was called in to support fell to the ground.

Charter-party. In Mercantile Law, is defined to be a contract, by which the owner or master of a ship hires or lets the whole or a principal part of it to a freighter for the conveyance of goods, under certain specified conditions, on a determined voyage to one or more places. A charter-party is generally under seal; but a printed or written instrument signed by the parties, called a memorandum of a charter-party, is binding if no charter-party be executed. A voyage may be performed in part under a charter-party, and in part under a parol agreement; but the terms of a charter-party cannot be altered by parol evidence, although they may be explained by mercantile usage. The instrument expresses the freight to be paid, and generally, but not necessarily, the burden of the ship; together with some usual covenants, and others at the discretion of the parties.

Chartists. The name assumed by a certain political party in England, composed chiefly of the working classes, who have embodied their principles in a document called the 'People's Charter,' the six leading points of which are universal suffrage, vote by ballot, annual parliaments, electoral districts, abolition of property qualification, and payment of members of parliament.

Chartulary. In Diplomats, a collection of the charters belonging to a church or religious house.

Charybdis (Lat.; Gr. *χάρυβδης*). In Mythology. [SCYLLA.]

Chaschisch. [ASSASSINS.]

Chase. Is part of a gun in front of the trunnions. In smooth-bored cast-iron guns it is the part between the second reinforce ring and the neck of the piece. [GUN.]

CHASE. In Forestry and rural matters, a row or rank of plants or trees, and more especially of hedge plants; also an extent of waste or forest land. The name is applied in England to some of those uncultivated lands which were set apart for the breeding of deer and other large game for hunting—as Waltham Chase, Cranborne Chase, Cannock Chase. Most of these, however, are no longer used for this purpose.

CHASE. In Nautical language, pursuit; also the vessel pursued.

CHASE

CHASE (Fr. *chassis*). In Printing, an iron frame three-fifths of an inch in thickness, in which the pages of type are wedged up to secure the letters from separating or dropping out in the process of printing. Chases are of different dimensions, according to the number of pages in a sheet, and the size of the paper: in the printing of books there are two bars fixed across at right angles, called crosses, so as to divide the chase into quarters for greater security. The thickness is always the same, however large may be the chase, being lower than the types, for the purpose of keeping the margin of the paper clean.

Chaser. The vessel pursuing. Also guns at the head and stern for firing when in chase.

Chasing or Enchasing. In Sculpture, the art of embossing or making bassi rilievi in metals. The work is punched out from the back, and then cut on steel blocks or puncheons, and cleared with small chisels and gravers.

Much chasing is done by filling the vessel to be chased with a composition of pitch, and then hammering with a point and chisel on the outside.

Chat-potatoes. Small potatoes, only fit for giving to pigs or boiling for poultry.

Chat-wood. Small sticks and spray, only fit for fuel.

Chathamite. A variety of Cloanthit found in Mica-slate at Chatham, Connecticut. It is chiefly an arsenide of nickel and containing 1·3 per cent. of cobalt.

Chatoyant (Fr.). In Mineralogy, the changeable light, resembling that observable in the eye of a cat, reflected by certain minerals. The reflections are sometimes coloured, as in Labrador Felspar; or pearly, as in Adularia; or silky, as in the fibrous variety of Gypsum called Satin Spar.

Chavica. A genus of *Piperaceæ*, separated from *Piper*, from which it differs in its perfectly unisexual flowers, which are sessile on spikes placed opposite the leaves. It yields some few important species, as *C. Roxburghii* and *C. officinarum*, which furnish the Long Pepper of commerce; and *C. Bata* and *C. Siriboa*, which furnish the Betel Pepper chewed by the natives of the Eastern Archipelago.

Chaya Root. The root of the *Oldenlandia umbellata*, cultivated upon the Coromandel coast as a red dye stuff.

Cheese. The curd of milk compressed into solid masses of different sizes and shapes; and, when intended for keeping, salted and dried, and sometimes coloured and flavoured. It is generally made from the milk of cows, but occasionally from that of ewes, and sometimes from the milk of goats. The following are the principal British cheeses: *Brickbat*, formed of new milk and cream, chiefly in Wiltshire, in the autumn, and sold in little square pieces about the size of brickbats. *Cheddar*, round thick cheeses, weighing from 100 or 200 pounds, solid, white, and homogeneous, and of the very best quality. *Cheshire*, large round thick cheeses, commonly weighing from 100 to 200 pounds each; homo-

CHEESE

geneous, and friable rather than viscid. They are made, like the Cheddar, from the whole of the milk and cream; the morning's milk being mixed with that of the preceding evening, previously warmed. *Derbyshire* is a smaller white rich cheese. *Dunlop*, originally made in Ayrshire, but now general throughout Scotland, is large, round, white, buttery, and weighs from 30 to 60 pounds. This and the Derbyshire cheese are very much alike in form, colour, and flavour. *Gloucester*, large, round, and mild; buttery rather than friable. There are two kinds, the single and double Gloucester; the single differs from the double merely in being half its thickness. *Green or Sage* cheese may be made of any of the other kinds by mixing the milk before it has curdled with a decoction of sage leaves, among which some put a few flowers of marigold and leaves of parsley. In the Highlands of Scotland the leaves or seeds of lovage are added to the sage, and communicate a very strong flavour. *Lincolnshire* is made of new milk and cream; it is quite soft, not above 2 inches thick, and will not keep more than two or three months. *Norfolk*, the weight is generally from 30 to 50 pounds; the curd is dyed yellow with arnatto or saffron; and though not a rich cheese, it is considered a good keeper. *Soft or Slip-coat* is a small soft rich cheese, which might almost be mistaken for butter, if it were not white; it must be eaten in a week or two after making. *Stilton*, so named from the town in Huntingdonshire where it was first brought into notice, but which is made principally in Leicestershire. It is rich, buttery, and white; and, unlike all the other cheeses which have been mentioned, it is twice as high as it is broad. It is much improved by keeping. It is the dearest of all English cheeses, the price being generally to that of Cheshire as 2 to 1, or 2 to 1½. In order to induce premature decay and the consequent appearance of age in these cheeses, it is said the makers sometimes bury them in masses of fermenting straw. *Cottenham*, so named from a town in Cambridgeshire; it differs chiefly from the cream cheese of Stilton in being flat, broader, and superiorly flavoured. The flavour is said to be owing to the rich grasses which grow on the Fens. *Suffolk*, or *Skim-milk*, is round and thin, weighing from 25 to 30 pounds each, and is the best keeping cheese made in England. *Wiltshire* resembles the Cheddar and Cheshire cheeses, but is of inferior flavour. *Yorkshire or Cream* cheese is the same as the slip-coat cheese already mentioned.

Foreign Cheeses.—The most remarkable of these are the following: *Parmesan* is chiefly made at Parma and other places in Lombardy, of the curd of skimmed milk hardened by heat. Its flavour is said to be owing to the rich pastures of that part of Italy, where plants, from the greater quantity of bright sunshine than in Britain, have doubtless their aromatic properties increased. *Swiss* cheese is of various kinds; but the chief sorts are the Gruyère or Jura cheese, and Schabzieger or green cheese;

CHEESE-ROOM

the last is flavoured with the seeds and leaves of the melilot, and is made, as its name imports, chiefly of a mixture of sheep's and goat's milk. *German cheeses* are of different kinds; but none are celebrated, unless we except that of Westphalia, which is made up into round balls or short cylinders, under a pound weight each. The flavour which this cheese acquires arises from the curd being allowed to become partially putrid before it is compressed. In Holland very good cheese is made, particularly the Edam and Gouda cheeses; the former is very salt, and keeps well at sea. In many parts of the Continent, and even in the interior of Poland and Russia, there are imitations of English cheese made; but what may be called the indigenous cheese of the Russian empire is nothing more than salted curd put into a bag and powerfully pressed, and taken to market as soon as it is made, in the same manner as butter is. In some places, instead of a press, the whey is forced out of the curd by putting it into a long cloth midway between the two ends, while a person at each end twists the cloth in an opposite direction, and thus wrings out the whey. In some Russian villages the curd is exposed for sale in small lumps, retaining the marks of the fingers, which shows that no other pressure has been employed than what can be given with the hand.

In France the Roquefort cheese is the most esteemed, and next that of Neuchâtel. The former somewhat resembles Stilton, but is much inferior; and the latter is a cream cheese seldom exceeding a quarter of a pound in weight.

Cheese-room. The common name in some parts of England for the Horse-mushroom, *Agaricus arvensis*, a species which grows in rings, and is largely gathered for market.

Cheetah or Cheeta. A *Mahratta* vernacular name, applied both to the *Felis jubata* and the *Felis Leopardus*. It is to the former species, or hunting leopard, that the term is confined in this country.

Chelognatha (Gr. *χελος*, a lip, and *γνάθος*, a jaw). An order of Myriapods or Centipedes, of which the lower lip is formed by the tongue and two mandibles.

Chelipoda (Gr. *χελος*, and *πους*, a foot). A family of Myriapods, in which a pair of feet form the lower lip.

Cheiomys (*χελω*, hand, and *μῦς*, mouse). A genus of Strepsirhine Quadrumana, peculiar to Madagascar. The Chieromys [*Aye-aye*] was discovered by the French voyager Sonnerat, since whose time no specimens had been brought to Europe. Professor Owen succeeded in obtaining a specimen from the Hon. H. Sandwith, which he dissected in 1863. Cuvier had placed it amongst the Rodents, misled by the appearance of the incisor teeth; but an examination of the brain leaves no doubt of its quadrumanous nature. The foreleg turns freely in the prone and supine positions; it is pentadactyle; the innermost digit stands out at an acute angle with the index, and is opposable to the other digits, making a prehensile hand, but in a less perfect

CHEIROPTERA

degree than in the Old-World or 'catarrhine' quadrumana. The second, fourth, and fifth digits have the ordinary thickness, the fourth being almost twice the length of the second. The third or middle finger is singularly attenuated; is rather shorter than the fourth digit; and is terminated by a slender curved claw. It is this seemingly atrophied digit which the Aye-aye inserts into the burrows of the wood-boring caterpillars, after it has gnawed down to and exposed them by its strong foreteeth, in order to extract the grub. The hind limb is longer than the fore limb, and is terminated by a more perfect hand; the 'hallux' or thumb being stronger, and set at a more open angle with the other toes, which are more like each other in length and thickness. The thumb has a flat, broad nail. From the external characters of the Aye-aye it might be inferred that it was of arboreal habits, the limbs being constructed chiefly for grasping, especially the hinder pair, as in all good climbers. The circular open eye, large iris, and wide pupil, reducible to a minute point when contracted, indicate a climber of nocturnal habits. The large and perfect ears bespeak the acuteness of their sense. The tail, long and bushy, but not prehensile, may add to the protective non-conducting covering of the well-clothed body during sleep. In a variety of particulars, its nearest approach is to members of the Lemnuring group. In ordinary zoological or external characters, Professor Owen considered that its nearest allies were certain Galagos of Africa (*Otolinus crassicaudatus* and *Otol. Alleni*).

Cheironectes (Gr. *χελω*, hand, and *πτερον*, a wing). A genus of spine-finned fishes, having the pectoral fins supported, like short feet, upon peduncles. By means of this organisation the cheironectes can creep over the mud or sand when left dry by the receding tide; they also propel themselves along by short leaps, and in this way seize upon insects which may be hovering about; whence they have obtained the name of frog-fishes. The gill-cavity is large, but the outlet very small, and the quantity of water which can thus be retained enables the cheironectes to remain out of water longer than fishes in general can do. The term *Cheironectes* is applied by Illiger to a genus of opossum having the hinder hands webbed. Some naturalists adopt this application of the term, and apply to the genus of fishes so called by Cuvier the name *Antennarius*, originally given to the cheironectes by Commerson.

Cheiroptera (Gr. *χελω*, a hand, and *πτερον*, a wing). An order of Mammalia, characterised by having the anterior extremities, and especially the hands, so modified as to serve the office of wings, the fingers being extremely lengthened, and connected together by a thin membrane. Of this order the common bat (*Vespertilio pipistrellus*) may be regarded as the type. The order includes very numerous and diversified species, which have been grouped by De Blainville, who has devoted an especial

CHEIROTHERIUM

study to them, into three principal divisions. Of these the *first* includes the largest species, called 'flying-foxes' (*Pteropus*): they are, however, vegetable-feeders, and are characterised by having the ears and nose of a simple form, the two innermost fingers of the hand armed with claws, and of the ordinary structure; the tail, and the web of skin connecting the hind-legs, and called the 'interfemoral' web, very short, or wanting; and lastly, by having the molar teeth separated by intervals, and simple structure. These bats are distributed over the warmer latitudes of the old continent, and extend to the islands of the Pacific Ocean. The *second* division has the nose complicated by variously shaped and grotesque membranous foliations; the first or innermost digit alone retains its ordinary structure and armature, the molar teeth are beset with sharp tubercles, and the food of these species consists of insects, or the blood of higher organised and larger animals. The vampire-bats of South America belong to this group, which also includes the horse-shoe bats (*Rhinolophi*) and other genera distributed over all parts of the Old World. The *third* division of *Cheiroptera* has the nose constantly simple: the other characters as in the second. It includes the bats properly so called (*Vespertilio*), which are uniformly insectivorous, and of small size.

Cheirotherium (Gr. *χείρ*, hand, and *θηρίον*, beast). This name was given by Kaup to a mammalian animal, supposed to have produced the handlike impressions on the Triassic sandstones of Hildburghausen and Lancashire. These have since been demonstrated to belong to a batrachoid reptile, the *LARYNTHODON*.

Chelæ (Lat.; Gr. *χηλαί*, claws). The first pair of forcipated extremities of the crab, lobster, and other crustaceans.

Cheliceræ (Gr. *χηλαί*, and *κέρας*, a horn). The term applied by Latreille to two appendages of the head of the Arachnidans, or spiders and scorpions, which appendages he considers as representing the mesial antennæ of the *Decapod Crustacea*, here converted into manducatory organs.

Chelidonic Acid. A white crystalline acid contained in the common *celandine* (*Chelidonium majus*). It forms definite salts with bases.

Chelidonine. A bitter alkaloid contained in the celandine.

Chelidonium (Gr. *χελιδόνιον*, *celandine*). A genus of *Papaveracea* found plentifully in a wild state in the neighbourhood of villages and old ruins in this country. The common Celandine, *C. majus*, has pinnately lobed leaves, and small yellow flowers succeeded by siliquiform pods, and is full of an acrid yellow milk, which is used to destroy warts.

Chelmsfordite. A crystallised greyish-white mineral composed of silicate of alumina and silicate of lime, found at Chelmsford in Massachusetts. It appears to have the same composition as Melonite and Scapolite.

CHEMICAL NOMENCLATURE

Chelonians, **Chelonis** (Gr. *χελώνη*, a tortoise). The order of Reptiles, including the tortoises, terrapenes, and turtles; characterised by the body being enclosed between a double shield or shell, out of which extend the head, tail, and four extremities. The land tortoises have the power of retracting all these parts within the shell.

Chemical Nomenclature. The early chemists distinguished the compounds which they discovered, by general names to indicate their source, and special names to indicate their appearance; thus—*horn silver*, *butter of antimony*, *oil of vitriol*, *spirit of salt*. The elements were named in an equally loose manner. The latter names have, in some cases, been retained, while the former have been almost wholly replaced by a system of names indicating as far as possible the composition and constitution of the compounds.

When a compound contains only two elements, its name is composed of their names, one of which is abbreviated, and the terminal *ide* attached. Thus a substance containing chlorine and sodium is called *chloride of sodium*. So *oxide of iron* (oxygen and iron), *sulphide of antimony* (sulphur and antimony), &c.; the name of the more negative element being always the one thus altered. When acids whose names end in *ic* combine with bases, the name of the resulting salt is composed of the names of its constituents, but the *ic* is dropped and the terminal *ate* substituted. Thus, carbonic acid and soda form *carbonate of soda*; nitric acid and potash form *nitrate of potash*; and so on. So acids whose names end in *ous*, form salts the names of which end in *ite*. Thus, nitrous acid and ammonia form *nitrite of ammonia*. Sulphurous acid forms *sulphites*, the *ur* being omitted for sake of euphony. The difference in the terminals *ic* and *ous* attached to the name of an element indicates its state of oxidation. For example, sulphur and oxygen combine in the proportion of one atom to three, and one to two; the former is called *sulphuric acid*, the latter *sulphurous acid*, *ic* always indicating a higher state of oxidation than *ous*. The abbreviated and slightly altered Latin and Greek numerals *mono*, *bi* or *bin*, *tri*, *quad*, *quin*; and *prot* or *proto*, *di* or *din*, *tri* or *tris*, *tetra*, and *penta*, indicate one, two, three, four, or five, &c. atoms of the substance to whose names they are affixed, the Latin most frequently referring to the negative constituent, the Greek to the positive. Thus *diniiodide of copper* is a compound containing two atoms of copper to one of iodine. *Biniiodide of mercury* would indicate two of iodine to one of mercury. *Tetracetate of lead* contains three atoms of acetic acid to one of oxide of lead; *trisacetate of lead* contains one of acetic acid to three of oxide of lead. *Sub* indicates an under or lower or smaller quantity of the substance to whose name it is attached. *Per* is another general rather than special prefix, having the opposite signification to that of *sub*. *Sesqui* indicates *one and a half* atoms of any element

or compound whose name it is associated with. Inasmuch, however, as half atoms are not supposed to exist, *sesqui* always indicates three atoms of the element to whose name it is affixed, united with two atoms of the second body forming the compound. Thus *sesquichloride* of iron contains three of chlorine to two of iron, not one and a half of chlorine to one of iron.

The above method of carrying out the principle of naming chemical compounds so as to indicate their composition and constitution, does not, however, meet the requirements of the chemists of the present day, as it can only to a limited extent be applied in describing chemical compounds of organic origin. The large numbers of atoms of each of the few elements which are associated in an organic molecule, precludes the idea of so naming the compound as to indicate mere composition, while expression of constitution is in most cases out of the question, simply because we are ignorant of it. Where anything is known of constitution, the same method of nomenclature is applied, but the frequent result is an almost unpronounceably long name. Moreover, views of chemical constitution being generally based on theory, all constitutional systems of nomenclature become modified and altered with the progress of science, and the result is the extreme inconvenience of having two or three names for one substance. [NOTATION, CHEMICAL.]

A congress of chemists held at Carlsruhe in the year 1860 discussed the question how best to put the language of chemistry into harmony with the actual state of the science. The conclusion arrived at was that there was at present insufficient ground for a general agreement on this subject, and that individual liberty was indispensable to progress.

Chemin des Rondes (Fr.). In Fortification, a passage left between the top of the revetment of the escarp and the parapet itself, so constructed that the defenders, themselves protected, can fire from it into the ditch.

Chemistry or Chymistry (the latter way of spelling this word implies the certainty that the *y* represents the Greek *υ*, and that the word is derived from the Greek *χημία*, *η χημική* being thus the science of juices, i. e. of fusion. This is, to say the least, very doubtful. Humboldt (*Cosmos* ii. 528) decides against it. The Greek forms *χημεία* and *χημεία* have been referred by some to *Chemi*, the name of the ancient Egyptians: this derivation, if proved, would make Chemistry the Science of the Egyptians: Niebuhr, *Lectures on Ancient History* i. 46).

Chemistry is a department of science, the objects of which are to investigate the nature and properties of the elements of matter, and their mutual actions and combinations; to ascertain the proportions in which they unite, and the modes of separating them when united; and to enquire into the laws and powers which preside over and affect these agencies. As an *art*, chemistry may be traced to a very remote period; but it can scarcely be said to have

existed as a *science* previous to the commencement of the seventeenth century: and in tracing its early history we shall find the principal materials upon which it is founded in the works of Bacon, Boyle, Hooke, Mayow, and Newton.

As *induction from experiment* is the exclusive basis of chemical science, little progress could be made in it till the utility of the ancient philosophical systems had been exposed, and their influence annihilated, and till the necessity of that form of severe experimental enquiry had been established which 'first procures the light, and then shows the way by its means.' Upon such foundations, laid by Bacon, the other philosophers whose names have been mentioned proceeded to bring together and arrange the materials which had been furnished by their predecessors, and were thence led into that train of true philosophical reasoning and research which roused the emulation of their immediate successors, and which has led in our times to the gigantic results of modern discovery.

It is well known that the alchemists had accumulated a number of valuable but isolated chemical facts, and that they had explored with considerable diligence the abstract properties and mutual agencies and relations of the greater number of natural products; but, with few exceptions, they neglected their useful and obvious applications, and wasted their labours upon unattainable and chimerical projects. Their discoveries and inventions, as Lord Bacon justly and forcibly observes, 'are well represented in the fable of the old man who left an estate to his children, buried, as he said, in his vineyard, which therefore they fell to dig and search for with great diligence; whereby, though they found no gold in substance, yet they received an abundant vintage for their labour. So assuredly has the search and stir to make gold produced a great number of fruitful experiments.'

Alchemical speculations, including the attempts at the conversion of mercury into gold, and the search after antidotes and universal remedies, were vigorously carried on during the sixteenth and seventeenth centuries; and many amusing accounts of the professors and adepts of those periods have been handed down to us by the chemical historians of the time. Those who are curious upon these subjects may consult Mangetus, *Bibliotheca Chemica*, and the *Theatrum Chemicum* of Elias Ashmole: the latter contains 'several poetical pieces of our famous English philosophers, who have written the hermetic mysteries in their own ancient language,' but their perusal is labour lost; not so, however, with Basil Valentine, Paracelsus, Van Helmont, and Glauber, in whose writings we not only find the materials so happily worked upon by Hooke and Mayow, but which also abound in announcements of important practical discoveries, and in hints to which many of the improvements of modern times may be plausibly traced.

Basil Valentine of Erfurt was born about the year 1400; his writings, although tinged

CHEMISTRY

with the follies of alchemy, are full of shrewd and intelligent remarks: he was the discoverer, apparently, of nitric and of sulphuric acid, and of many antimonial preparations, which are fully described in his *Triumphal Chariot*. Philip Hochener, more commonly known under the name of Paracelsus, and who died in 1541 at Salzburg, in the forty-third year of his age, is chiefly celebrated for the boldness and assiduity with which he introduced chemical preparations into the practice of medicine; he did little, however, as a discoverer. Van Helmont, one of the soundest writers of his period, was the first who seems to have paid attention to the nature of gaseous bodies, and to the distinction between permanent gases and vapours: the word *gas* first occurs in his works; and under the term *gas silvestre*, he seems to allude to what was afterwards termed *fixed air*. None, however, of these early practical chemists come into competition with Glauber. He was an active experimentalist and an acute reasoner; and among his discoveries we may enumerate the distillation of muriatic acid from a mixture of sulphuric acid and common salt; the purification of the residuary sulphate of soda, which he termed *sal mirabile*, and which still bears his name; the production of ammonia by the distillation of bone, and its conversion into *sal ammoniac* by the addition of *spirit of salt*; the preparation of sulphate of ammonia, which he terms *secret sal ammoniac*; the formation of blue vitriol by the action of sulphuric acid upon the green rust of copper; the composition of numerous earthy, alkaline, and metallic salts; and lastly, the evolution of vinegar during the destructive distillation of wood, for which he describes and delineates the distillatory apparatus, under the name of 'a press for extracting the juice of wood,' and the uses of which, together with those of the oil of tar and other products, he describes at length, closing his discourse with a statement of his apprehension that he shall be by many disbelieved: but 'it contenteth me,' he says, 'that I have written the truth, and lighted a candle to my neighbours.' Glauber also published a pamphlet, entitled, *The Consolation of Navigators; in which is taught how they who travel by sea may preserve themselves from hunger and thirst, and also from those diseases which are wont to happen in long voyages: written for the health, comfort, and solace of all those who travel by water for the good of their country*. The sensible plan of employing extract of malt as a portable vegetable diet, and diluted muriatic acid to quench thirst, is here recommended; and many of the medicinal uses of that acid are dwelt upon, among which are some that have been claimed as recent discoveries. On the whole, there is no author, contemporary with Glauber, who has written so much to the purpose, and who, as it were, anticipated so many of our modern scientific improvements.

Reverting to the names of Boyle and his eminent associates, we are reminded of the

origin of the *Royal Society of London for the Improvement of Natural Knowledge*, which was incorporated by Charles II. in the year 1662, and of which Boyle and Hooke were active and distinguished members. Boyle died in 1691. His station in life, his mild and prepossessing disposition, his strict honour and integrity, and the unaffected earnestness with which he promoted experimental enquiry tended to shed a lustre on his pursuits, to elevate their character with the world, and to draw into their precincts many who without such an example would have passed their lives in that listless inactivity then too common with those upon whom fortune smiled: among these Mr. Boyle made many converts.

Boyle's *Essays on the Successfulness and Unsuccessfulness of Experiments*, and the Preface to his *Philosophical Writings*, are in the genuine spirit of experimental research; but the new and important aspect assumed about this time by such pursuits is perhaps chiefly due to Dr. Robert Hooke (born in the Isle of Wight in 1635, and died in London in 1702). Among his views and discoveries which bear upon the progress of chemical philosophy, the most important are those relating to the phenomena of combustion, and to the part which the air performs in that process; his notions upon these subjects are remarkable for their boldness as differing from the prevailing theories of the day, and for their correctness as superseding the objections to which those theories were liable. From the hints contained in the writings of the alchemists, it appears that the phenomena of combustion were referred to a subtle and highly volatile principle, which, agitated and expanded by heat, produced *flame* and *fire*. When metals were exposed to the action of heat, the greater number of them were observed to alter their appearance, and losing their brilliancy, became converted into an earth-like powder or *calx*. It was generally admitted that in this process the particles of the combustible were thrown into violent vibrations, and in that way transformed into heat and light. But it had been also remarked, that in certain cases of combustion, and especially as regards the metals, the phenomenon was attended by an actual increase of weight in the burning body, and that this result was incompatible with the theory which assumed the conversion of the combustible into heat and light, or the evolution of that principle of inflammability which by Beccher and Stahl and the chemists of that school was termed *phlogiston*. About the year 1630 a remarkable tract appeared in France relating to this subject, by Jean Rey, a physician of Perigord. Le Bruin had melted two pounds six ounces of lead, and found that in six hours the whole had been converted into calx; but that instead of having lost *phlogiston*, or any other ponderable matter, it had actually increased in weight to the extent of some ounces. Puzzled by this result, he consulted Rey as to its cause, who immediately undertook an experimental en-

quity, which led him to refer the increase in weight in this and similar cases to the *fixation of air*. This inference was amply supported by the researches of Boyle and of Hooke: the former found that no combustible would burn under the exhausted receiver of the *air-pump*, and consequently that the presence of air was requisite; and Hooke, finding that however intensely charcoal was heated, it would not burn when air was excluded, infers 'that air is the universal dissolvent of inflammable bodies, and that this dissolution generates heat, which we call *fire*.' But he went a step beyond this, and attributes the power of supporting combustion to a principle in the atmosphere, 'like unto, or the very same as that which is fixed in saltpetre;' for he had observed the power of that salt as a supporter of combustion. His words are as follow: 'The dissolving parts of the air are but few, and hence the atmosphere is like those spirits which have much phlegm mixed with them, and become soon glutted; whereas saltpetre abounds more in those solvent particles, and hence a little will dissolve a great sulphurous body quickly and violently; and as other solvents, though but weak, quickly consume the dissoluble body if the supply be renovated, so air applied to a shining body by a bellows will dissolve it as rapidly as saltpetre.' From all which he concludes that there is no element of fire, but that flame results from the mutual chemical action of the combustible upon a part of the atmosphere. (Hooke's *Micrographia*.) Hooke also alludes to the part performed by air in the process of respiration; and in his *Lampas*, published in 1677, has given a beautiful explanation of the burning of a candle. He attributes the light and heat to the action of the air upon the combustible matter of the flame, and shows that the interior of the flame is not luminous, by the simple expedient of viewing its section through a thin piece of glass or of mica.

These doctrines of Hooke were further illustrated by John Mayow (born in Cornwall, 1645; died in London, 1679), who not only experimentally corroborated them, but pointed out the connection between combustion and respiration, and showed that that part of the air concerned in the support of flame was also essential to the life of animals. He placed a candle under a bell-glass, and when it would no longer burn, he found that on rekindling it, it was immediately extinguished by the same air; he then placed a mouse in a confined portion of air, and it soon manifested the want of its renewal; he then put the mouse under the same bell-glass with the candle, and found that it only lived half the time that it had survived without the candle; he then reversed the experiment, and endeavoured to burn a candle in air which had been breathed, and finding that it went out, he concluded that the 'nitro-aërial particles' of the air were as essential to respiration as to combustion, and that they were in both cases *absorbed*; and he even refers *animal heat* to the influence of the air upon the blood.

But Mayow's claim to a distinguished place in the history of chemistry is not merely founded upon the sagacity with which he followed up these views; he was the first who distinctly expounded the nature of *chemical affinity*, and who taught its independence of those mechanical forms of the particles of matter to which it had been referred, and showed, contrary to the prevailing tenets, that in cases of combination the particles of the acting bodies were not annihilated, but that they still existed in the compound, and might again be elicited from it, with all their former powers and properties. These notions he illustrates by a series of extremely apposite experiments; and proceeds to explain *decomposition* upon the principle of inequality in the respective attractive forces of the acting bodies, a doctrine which was afterwards verified and further explained by Newton, whose masterly sketch of a theory of chemical attraction, given in the queries to the third book of *Optics*, is nearly in the language and entirely in the spirit of his predecessor. The theory of combustion and of affinity, thus established upon the basis of experiment by Hooke and Mayow, constitute the foundation upon which most of the superstructure of modern chemistry rests; the former was extended and embellished by Lavoisier, and the latter has gradually risen into the atomic and equivalent doctrine. There are three principal points connected with the vast extension and importance of chemical science as we now find it, which it becomes necessary therefore to notice; namely, the investigations relating to the philosophy of *heat*, those connected with *pneumatic chemistry*, and those establishing the connection of *electrical* with *chemical* phenomena.

It was not till towards the middle of the seventeenth century that such perfection was given to the construction of the *thermometers* as to enable it to be used as an accurate and comparative measure of temperature. Dr. Halley seems to have been the first who applied the uniform temperature of boiling water to obtain one fixed point for its graduation; the constant temperature of water in the act of freezing seems also to have been noticed about the same time by the Florentine academicians, and by Newton; and these two points being thus determined and ascertained, together with the causes of their occasional discrepancies, the graduation of the thermometer became easy, especially when the advantages of mercury had been pointed out by Halley, together with the mode of sealing it in the thermometer tube. [THERMOMETER.] But the great and important step in the philosophy of heat was the consequence of Dr. Black's discovery of the state in which heat exists in liquids and vapours, and upon which he founded his theory of *latent heat*. This theory gave a satisfactory solution of a multitude of natural and artificial phenomena previously unexplained or unobserved, and laid the foundation of those wonderful improvements in the theoretical

and practical construction of the steam-engine which were soon afterwards carried into effect by Watt.

Dr. Black was born in 1728 on the banks of the Garonne, and was educated at Belfast, and afterwards at Glasgow: in 1766 he was appointed to the chemical chair in the university of Edinburgh, where he died in 1799. He not only made the grand discovery of the latency of heat, but he enriched chemistry with other discoveries; among which that of the presence of carbonic acid in the mild earths and alkalies, and the cause of their causticity, was especially perfect and important. These facts, including also the discovery of carbonic acid, or, as it was then called, *fixed air*, were first published in 1766; his ideas respecting the combinations of heat with ponderable matter were perfected in 1764.

Another and distinct series of enquiries, having important bearings upon the philosophy of heat, had their origin with the Florentine academicians towards the end of the seventeenth century, and were afterwards sagaciously followed up by Scheele, Leslie, and others; they relate to the *phenomena of radiation*, to the manner in which heat is propagated through space, to those of its emanation from luminous and incandescent bodies, and to its connection with light.

Pneumatic Chemistry had its origin in the experiments of Hooke and Mayow, and was subsequently extended by Hales, and more especially by Priestley. Mayow obtained hydrogen gas by the action of iron on dilute sulphuric acid, and observed the formation of nitrous gas during the action of aquafortis upon the same metal; but it was not till the commencement of the last century that the distinctive characters of the gases and their importance as chemical agents began to be duly appreciated. Connected also with this subject is the rise and progress of the chemical physiology of vegetation. Dr. Stephen Hales was born in Kent in 1677, and died at Teddington in 1761. He began the communication of his researches to the Royal Society in 1717, and in 1727 published his *Statical Essays, containing an essay towards a natural history of vegetation, of use to those who are curious in the culture and improvement of gardening; also a specimen of an attempt to analyse the air by a great variety of chemico-statical experiments, which were read at several meetings before the Royal Society*. In 1733 a second volume of these essays was published, containing *Hæmostatics, and experiments on the stone of the kidney and bladder*. In his various experimental researches detailed in these essays, Dr. Hales describes many curious facts, and shows much ingenuity in the contrivance of apparatus; but he furnishes a striking instance of the facility with which the mind is led away from the true path of discovery by preconceived opinions; for having predetermined that the various gaseous products which he obtained were mere modifications and contaminations of common air, he missed much

that was fairly within his grasp. He observed, for instance, that air was absorbed during the combustion of phosphorus in close vessels, but he examined none of the products; he collected the air evolved during the destructive distillation of wood, and found it fatal to animals; from Newcastle coal he obtained one-third of its weight of gas; and from nitre, 180 times its bulk; but he did not leisurely examine any of these products. He found that iron filings and oil of vitriol would not evolve gas unless water was present; but instead of stopping to examine the properties of the hydrogen gas which he thus obtained, he hastens on to irrelevant observations, being more eager to multiply experiments than to examine their results. In the same way he details with minute accuracy the quantity of air generated during the distillation of blood, tallow, sal ammoniac, and many other substances, without drawing a single useful inference. In his experiments on respiration, too, he obtained results of extreme interest, and is often upon the verge of most important discoveries; but instead of being incited by the novelty of his results, and the extent of the field of investigation opened by his researches, he drops them upon the occurrence of the slightest difficulty. His examination, however, of the motion of the sap in vegetables was pursued upon a more regular and satisfactory plan; he ascertained the quantity of matter imbibed and perspired by several plants and trees; the proportion daily lost by the leaves, and their influence upon the absorptive powers of the root; and the relation of various states of the atmosphere as to temperature and moisture upon these functions. He endeavoured to confer different flavours upon fruits by impregnating the soil with perfumed waters, and he found that the odorous particles were rejected by the living vessels, but that they affected the dead parts of the tree; he compares the functions of the leaves of evergreens with those of deciduous shrubs and trees; he notices the effect of cutting a ring of bark off the branch of a tree in promoting the growth of its leaves and fruit; and, lastly, shows that air is sometimes absorbed or inspired by plants, and gives some interesting views relative to the germination of seeds.

When it is recollected that Hales wrote at the commencement of the last century, that few models of good scientific composition were then extant, and that a pompous and obscure style was prevalent among many of his contemporaries, we must admire the perspicuous and unadorned manner in which he details his facts and observations. He has in this respect all the merit which belongs to Boyle without his diffusiveness; and a pleasing vein of sound and unaffected morality accompanies his arguments, and leads him, whilst endeavouring to unveil the mysteries of nature, to direct our attention with becoming modesty to the extreme penny of man's wisdom, when compared with the admirable adjustments of causes and effects discoverable in the lowliest works of the Creator.

CHEMISTRY

But although Mayow, Hooke, and Hales had done much towards establishing the interest and importance of gaseous chemistry, it is to Dr. Joseph Priestley (born at Fieldhead, near Leeds, 1733; died in Pennsylvania, 1804) that we owe the principal progress in this branch of science. He directed his attention to it with a degree of activity and skill then peculiarly his own, and in the number of his discoveries left his contemporaries far behind, while he certainly rivalled them in their interest and importance, which is the more surprising when we reflect that he generally seems to have considered his philosophical studies as subordinate to his more severe and serious occupations. He first turned his attention to chemistry about the year 1768. He used to amuse himself with experiments on fixed air and on artificial mineral waters; and one experiment, as he says, leading to another, he soon collected those materials which he laid before the Royal Society in 1772, under the title of *Observations on Different Kinds of Air*. It was on the 1st of August, 1774, that he made the great discovery upon which so much of the subsequent progress of chemical science has depended, namely, that of *oxygen gas*. He obtained it by exposing a quantity of *red precipitate of mercury* to the action of the sun's rays concentrated upon it by a lens; the red precipitate was contained in a flask filled up with mercury, and inverted in a basin containing the same metal. 'I presently found,' he says, 'that by means of this lens air was expelled from it very readily. Having got several times as much as the bulk of my materials, I admitted water to it, and found that it was not imbibed by it; but what surprised me more than I can well express, was that a candle burned in this air with a remarkably vigorous flame, very much like that enlarged flame with which a candle burns in nitrous air exposed to iron or liver of sulphur; but, as I got nothing like this remarkable appearance from any kind of air besides this particular modification of nitrous air, and I knew no nitrous acid was used in the preparation of *mercurius calcinatus*, I was utterly at a loss how to account for it.' He then goes on to show that *red lead* and *nitre* also afford oxygen at a red heat, and calls it, consistently with the theory of combustion which was then prevalent, *dephlogisticated air*, regarding it as common air deprived of phlogiston, and consequently possessed of a powerful affinity for that imaginary principle.

Shortly after the discovery of oxygen, Priestley ascertained that plants had the power of purifying air which had been vitiated by the respiration of animals, and that oxygen was evolved by aquatic plants in water containing carbonic acid. Nitrous and nitric oxide, muriatic acid, and ammonia were also amongst his gaseous discoveries. In 1772 Dr. Rutherford had demonstrated that a large portion of the atmosphere consisted of a peculiar gas differing from fixed air, yet like it extinguishing flame and unfit for respiration; to this component

part of the atmosphere Dr. Priestley gave the name of *phlogisticated air*, and pointed out the means of ascertaining its relative proportion to the oxygen of the air by the agency of nitrous gas.

Another celebrated name connected with the progress of this department of chemical science is that of Cavendish (born in London, 1731; died at Clapham in 1816). In 1776 he presented the Royal Society with a dissertation on inflammable, fixed, and nitrous air. The two latter gases had been well described by his contemporaries: but nothing very precise was known respecting inflammable air, till its sources and properties were described in Cavendish's paper. He found that it was the lightest known substance, and showed that by combining with oxygen, *water* was the only result; hence the term *hydrogen* subsequently applied to this gas. Cavendish also discovered the composition of nitric acid; and by passing a succession of electric sparks through common air, and through artificial mixtures of oxygen and nitrogen, he succeeded in effecting their combination, and in producing that acid.

Two capital and extremely important steps were thus made in chemical science, chiefly by the joint labours of Priestley and of Cavendish; namely, the composition of the atmosphere and of water; and about the same time Scheele (born at Stralsund in 1742, and died at Köping, near Stockholm, in 1786), in his dissertation on manganese, made known the existence of chlorine, or, as he then termed it, of dephlogisticated muriatic acid gas. His *Observations and Experiments on Air and Fire* and on *Heat and Light*, are also masterly productions, and contributed, in conjunction with the labours of his eminent contemporaries, to invest chemistry with a degree of interest and importance which gave it an entirely new and distinct aspect.

It was at this period that Lavoisier (born in Paris in 1743, where he fell a victim to the Revolution, May 8, 1794) and his associates in Paris undertook that celebrated reform of chemical nomenclature which ended in the banishment of phlogiston, and introduced a logical precision into the precincts of chemistry. Lavoisier experimented upon a magnificent scale, and with a degree of statistical accuracy which stamped his researches with a new and valuable character. By a series of beautiful experiments he determined the relative proportions of the elements of the atmosphere and of those of water; he rejected all supporters of combustion except oxygen, and regarded it as the great source of the heat and light evolved during that process; he endeavoured to prove that gases were constituted by the union of ponderable bases with *caloric*, or the *matter of heat*, and examined, upon a splendid scale and with magnificent apparatus, the results of the combustion of sulphur, phosphorus, carbon, and the metals; he inferred that oxygen was the universal *acidifying* principle; and by a series of well-conceived researches he demonstrated the

CHEMISTRY

identity of charcoal and the diamond, and showed that when burnt in oxygen they yielded carbonic acid gas. Lavoisier was also the first who examined with requisite accuracy the products of the distillation of animal and vegetable substances; he also enquired with more success than any of his predecessors into the phenomena of fermentation, and, by examining the contents of certain vegetable juices, previous to and after that process, he drew some curious and important conclusions respecting the changes that take place: he also extended and corroborated Scheele's views as to the importance of the chemical agencies of light.

These and a variety of other details are embodied in Lavoisier's *Éléments de Chimie*, which appeared at Paris in 1789; a work which eminently displays the extent and perspicuity of his views as a theoretical and experimental philosopher, and which contains a masterly refutation of the phlogistic doctrines. The abstract facts, however, upon which this refutation rests, may be traced to Mayow, Hooke, Priestley, and Scheele. It has been stated that the prominent features of the French theory were its explanation of the phenomena of combustion and of acidification, the presence of oxygen being deemed essential in both cases. That air is the food of fire was known at a very remote period: that it causes the increase of weight sustained by metals during their calcination was shown by Rey early in the seventeenth century; that a part only of the atmosphere, identical with a matter contained in saltpetre, is concerned in the support of flame, was explained by Hooke in 1667; and that the vital, or igneous spirit, as he terms it, contributes to the formation of acids, was asserted by Mayow in 1674. Here, therefore, without even infringing upon the eighteenth century, we have, in explicit detail, the principal facts and arguments requisite for the construction of the French theory; and if to these we add the discovery of oxygen by Priestley, and of the composition of water and of nitric acid by Cavendish, what then becomes of its title to originality?

The influence of the researches connected with the philosophy of heat, and of those relating to the production, properties, and constitution of the gases, upon the improvement and extension of chemistry, will now be apparent; but one of the most fertile sources of its recent progress is of a distinct and remarkable origin, namely, the discovery of the *chemical influences of electricity*.

In 1790 Galvani of Bologna ascertained that certain spasmodic or convulsive contractions might be produced by the action of electricity upon the nerves of a recently killed animal; and that if the sciatic nerve of a frog be laid bare and touched with a piece of zinc, whilst at the same time the muscle is touched with gold, similar effects to those of electricity are produced whenever the metals are brought into contact, or connected by conductors of electricity; if non-conductors were used, no spasm ensued. He accounted for these and similar

effects by assuming that the nerves and muscles were in opposite electrical states, and that the spasms were the consequence of their annihilation or discharge.

Volta, on the other hand, finding that two different metals were essential, referred the phenomena to the electromotive power of the metals; and, following up this idea, he soon succeeded in producing that extraordinary form of electro-generative apparatus which is now known under the name of the Voltaic pile or battery, consisting of alternations of two metals with an intervening fluid. Zinc, copper, and diluted acids were the substances generally resorted to. It has since been shown by Faraday that *chemical action* is the exclusive source of the electricity of these Voltaic arrangements; but their history and the theory of their phenomena will be given elsewhere.

In the year 1800 the *chemical powers* of the Voltaic pile were first observed in regard to the decomposition of water and certain saline solutions, by Messrs. Nicholson and Carlisle; these were more accurately investigated in 1803 by Hisinger and Berzelius, and in 1806 Davy communicated his celebrated lecture, *On some Chemical Agencies of Electricity*, to the Royal Society. He had previously (1801) given a paper to the society containing an account of some galvanic combinations formed by the arrangement of single metallic plates and fluids, analogous to the galvanic apparatus of Volta; but it was not till the publication of the Bakerian Lecture above referred to that the importance of *electro-chemical science* could be appreciated. It contains a masterly outline of the subject; and its details present a fine specimen of experimental enquiry, especially in reference to the manner in which he traces out the decomposing powers of an electrical current in effecting the separation of the elements of water; the skill with which the conflicting results of other experimentalists are examined and explained; the caution with which he proceeds from experiment to theory; and the sagacity with which he employs theoretical views as the source of new experimental enquiries. The path which he had thus opened for himself, led him on to the most important and extraordinary results, among which were the decomposition of the alkalis and earths, and the discovery of an entirely new class of metals.

But the eradication of established errors is perhaps a more difficult task than the promulgation of new theories; and in this Davy rendered a memorable service to chemistry by his several papers on *Oxymuriatic Acid*, in which he successfully establishes the views of Scheele regarding its nature, and refutes and subverts those of the French school, which had been sanctioned by the chemists of Europe: he demonstrates the existence of acids without oxygen, and lays the foundation of the theory of the *hydracids*.

To these masterly researches Davy added a third series, also of considerable importance:

those relating to the *safety lamp*. His first paper upon this subject is printed in the *Philosophical Transactions* for 1816, and was followed by four others. When he found that flame would not recede through tubes of very small diameter, the idea occurred to him of constructing a lamp which should have no connection with the surrounding air except by such tubes; and he inferred from previous experiments that such a lamp might safely be employed in coal mines infested by fire-damp. He then endeavoured to ascertain the extent to which the tubes might be shortened without interfering with this principle of safety, and was thus led to cut them down, till their transverse section resembled a series of meshes. This approach so closely to *wire-gauze* that he was induced to try how far that tissue would prevent the passage of flame: and finding it effectual, he employed it in the construction of his lamp, and ultimately adopted the simple and efficient arrangement now in general and successful use. During the experimental investigations upon which the discovery of the safety lamp was founded, Davy ascertained a number of curious facts respecting the constitution and temperature of flame, which, with other parts of his general enquiry, are not less ingenious than original. In November 1820, Sir H. Davy became president of the Royal Society, and continued to contribute papers as heretofore, some of them upon subjects of much interest, ably and philosophically discussed: among them the essays on the modes of protecting the copper sheathing of ships deserve especial notice; they have furnished hints for the preservation of iron and other corrodible metals from the influence of air and water, and have led to results of great practical importance. In the course of the year 1827 his health became seriously impaired; he passed the greater part of the year 1828 in Italy, and terminated his memorable existence at Geneva in May 1829, in the fifty-second year of his age.

We have now briefly sketched the principal circumstances in the history of chemistry bearing upon its origin and progress as a science, without, however, adverting to the labours of contemporaries; it remains to add a short notice respecting the art of *Analysis*, and the important consequences of which the prosecution of that branch of the science has been productive.

Analysis was first scientifically pursued by Bergman of Sweden. He was born in 1735, and died in 1784, in consequence, as is said, of too intense application to his studies. The use of *tests* for the discovery of certain substances held in aqueous and other solutions, is first particularly dwelt upon by Boyle. He used vegetable colours for the detection of acids and alkalies, and noticed the cloudiness produced by nitrate of silver in a solution of common salt. In 1667 Du Clos undertook an examination of the mineral waters of France; and in 1686 Hierne published some clever experiments upon the same subject in Sweden. In 1726 Boulduc

used spirit of wine to precipitate the salts insoluble in that menstruum; in 1756 Vemel pointed out the existence of fixed air in the waters of Selters, Spa, and Pyrmont; Lane, in 1769, showed the method of imitating chalybeate springs; and in 1772 Priestley published directions for saturating water with fixed air. The above and other tests were particularly examined, their accuracy compared, and the best modes of applying them pointed out, by Bergman: his dissertations on the waters of Upsal, on sea-water, and on the artificial preparation of medicated waters, each exhibit proofs of his skill as an analyst, and accuracy as an experimenter. He also turned his attention to the analysis of minerals; his essay, entitled *De Minerarum Docinasiâ Humidâ*, must be considered as the parent source of that branch of analytic chemistry so successfully followed up, though upon a limited scale, by Scheele, and in the improvement and extension of which Klaproth passed his long and laborious life. Klaproth was born at Wernigerode in Prussia in 1743, and died at Berlin in 1817. He published 207 essays, in his *Contributions towards the Chemical Knowledge of Mineral Substances*. Another eminent name among chemical analysts is that of Vauquelin, who died at an advanced age in Paris in 1829. He was originally a peasant boy in Normandy, and afterwards was employed in Fourcroy's laboratory, where he not only acquired great dexterity in the ordinary duties of his situation, but became an expert and original analyst. He afterwards rose to high eminence in his profession; and his numerous and important contributions and discoveries are lasting monuments of his skill and industry.

Among the improvers of analytical chemistry in this country, Chenevix, Howard, and Tennant deserve particular mention; but to none is this part of the science more deeply indebted than to Dr. Wollaston. With him and Davy all that is practically useful in the theory of definite proportionals, or, as it is often called, the *Atomic Theory*, may be said to have originated; though the facts upon which it is founded were chiefly furnished by the German analysts, and by Higgins of Dublin.

We have in another place given some account of this important subject, and have endeavoured to explain the facts upon which it is founded, and the results to which it leads: its promulgation with us is mainly attributable to Wollaston's suggestions contained in his paper *On a Synoptic Scale of Chemical Equivalents*, brought before the Royal Society in November 1813. Many years previously he had established the important doctrine of multiple proportions, in a paper *On Superaacid and Subacid Salts*. He now showed the practical applications of which the theory was susceptible; and, by connecting the scale of equivalents with Gunter's sliding rule, has put into the hands of the chemist an instrument infinite in its uses, and equally essential to the student, the adept, and the manufacturer.

There remains to be noticed a distinct branch of chemistry of extreme interest and importance, but beset with peculiar difficulties; namely, that relating to *organic substances*. Some progress was made in it by Scheele, but it has chiefly been enriched by the labours of modern and contemporary philosophers, and in their hands has assumed an entirely new aspect. The composition of organic bodies may be viewed in two ways; either as relates to their ultimate elements, or to their proximate groups. The former are remarkably few in number, and are almost exclusively confined to four; namely, carbon, hydrogen, oxygen, and nitrogen. These, by their varied and extraordinary union, give rise to innumerable secondary products, or proximate principles. That the same elementary forms of matter should give rise to such infinitely varied products, merely in consequence of the varying proportions in which they are combined and the circumstances under which they have been presented to each other; that food and poisons, alkalies and acids, sweets and bitters, and, in short, the most opposite and dissimilar qualities, should arise out of such causes—is extremely remarkable; and although every day is adding to our information, and clearing difficulties from this department of chemistry, it is but in its infant state.

In looking at the present state of chemistry, it must be allowed that it exhibits a most promising aspect: the study of its abstract principles is calculated to keep the curiosity constantly on the alert, and awaken an intense and peculiar interest; and it is quite impossible to glance at its recent progress, and at the extraordinary discoveries which are daily rewarding the labours of its skilful cultivators, without anticipating most important consequences. Should its future progress only equal that of the past, it must lead to results deeply affecting the interests and welfare of mankind; but as it has hitherto acquired strength with its progress, its wonders may be expected to accumulate in a much higher ratio. We already seem to be on the brink of some great discovery connected with those powers and properties of matter which we call *electrical*. Their association with, and convertibility as it were into, heat, light, and magnetism, and their identity with the cause of chemical affinity, have already been turned to great account; and it is only necessary to assume the possession of a more unlimited command than we at present enjoy over the production or evolution of this extraordinary agent, less dependent and scanty means of summoning it into existence or activity, and a more intimate acquaintance with its forms and qualities, to confer the highest interest upon our speculations. Its chemical powers would then be perpetually called into action as a substitute for the more sluggish or circuitous and difficult methods of ordinary decomposition. Its single application to the evolution of oxygen and hydrogen from water would alone work wonders; whilst the facility of its conveyance

and transmission, its ubiquity, and its varied attributes in those different states which for want of more explicit knowledge of their cause have been termed *quantity* and *tension*, seem to point it out as of unlimited application to human uses. Through its instrumentality telegraphic communication has not only been accelerated, but rendered independent of weather, and equally easy by night as by day; and even in the present state of this invention, there seems no reason against such conveyance of our thoughts, wants, and wishes, so as to transmit them over the globe with a rapidity as much beyond all previous experience, as the travelling on a railroad exceeds that of a common carriage.

Connected, therefore, with the progress of the higher departments of chemical science, and indeed intimately interwoven with it, is the advancement of its application to all the arts of life. It is often supposed that the successful applications of chemistry to the arts have been rather the results of accident or chance than the consequence of those apparently abstract studies, and curious rather than useful discoveries, as they are called, in which the truly philosophical chemist is engaged, and in which his labours terminate; but experience justifies no such conclusion. There can be no doubt that Black's researches into those effects of heat which are connected with changes in the state and form of bodies, and especially with the constitution of vapour, led Watt into that train of reasoning by which his improvements in the steam-engine were ultimately effected. Many of the wonders of modern chemistry must be referred to Galvani's experiments on a dead frog. They led Volta to the construction of the electric pile; and, in the hands of Davy and his successors, what important conquests have been attained, and what extraordinary consequences are daily flowing from a source so apparently unpromising and irrelevant! Independent of the new agents which have been placed in the hands of the experimentalist, and of the new and important theoretical considerations which arise out of them, the whole aspect and character of a great department of physical science has been wonderfully changed, extended, and improved; the cause of magnetism has been developed; and a power no less extraordinary and applicable to human uses than light and heat, perhaps indeed the parent of both, is gradually showing us its mysterious relations. Of two great practical consequences have these enquiries already been productive; namely, the electric telegraph, and the preservation of metals from corrosion. That others are upon the eve of their development cannot be doubted; and in proportion as our knowledge of this agent, and consequent power over it, is extended, those ends must certainly be attained which we have above ventured to anticipate.

From other departments of this science we are constantly acquiring similar benefits: the progress of gas illumination, the great improve-

CHEMISTRY

ments in metallurgic operations, in the arts of dyeing and calico-printing, in the manufacture of cements, in the preservation of timber from dry-rot, in gilding and silvering the metals, are only a few of the cases in point; even the difficult and apparently isolated researches into the relative proportions of the ultimate elements of the proximate organic products, and the application of the atomic theory to those researches, have not been fruitless, considered in reference to what are termed their practical results and popular and useful applications. The brewer and the distiller are reaping the benefits of such enquiries; the conversion of starch, and even of wood, into sugar, are the practical consequences of theoretical inferences. From the destructive distillation of ligneous matter we are already furnished with our chief supply of vinegar, and with a liquid which, as a combustible and a solvent, has to a great extent superseded the use of alcohol, and may perhaps replace it as an intoxicating stimulant: the sawdust of certain woods has been shown susceptible of conversion into nutriment; and the analysis of bone points it out, when properly prepared, as almost equal to its weight of flesh as an article of human food. All the forms of ammonia are now derived from what were once called the waste products of gas-works, and coal-tar has become the parent of a host of brilliant dyeing materials. In short, of the arts of life the greater number are dependent upon chemical principles; many of them, and perhaps the most important, are exclusively so; others, though apparently mechanical, involve chemical principles: hence the great and growing importance of chemical science as a branch of general education bearing upon political economy and upon the prosperity of the arts and manufactures.

Having given this outline of the rise, progress, and applications of chemical science from an early period to the beginning of the present century, we must refer to other articles for more explicit information upon the different heads that have been here briefly noticed. In reference to further details respecting the history of this department of knowledge, especially as relates to alchemy and to the history of chemical inventions, we may refer to Dr. Thomson's *History of Chemistry*, and to the prefatory chapter of the sixth edition of Brande's *Manual*.

The extent necessarily chemistry in a map of human knowledge will be evident from the brief definition of the science given at the outset of this article; for it not only leads us to enquire into the composition of every product of nature and of art, but to examine the elements of all the forms of matter, and the laws which govern their mutual actions and reactions. The questions which a chemist

science except upon the basis of experimental research. Accordingly, when a body of unknown nature is presented to a chemist, he endeavours, first, to ascertain whether it be a *simple* or a *compound* substance. If simple, to what class of elementary bodies does it belong? is it combustible or incombustible? is it electro-negative or electro-positive? how is it affected by heat? what are its relations to other forms of matter? what its powers of combination? what are the proportions in which it unites with other substances? what are its characters and those of its combinations as a chemical and physiological agent? what are its uses in the arts and in medicine? If it be a compound substance, he enquires into the nature and number of its component parts: are they new, or are they known elements? in what proportions are they combined? He also examines its thermal and electrical relations, and its useful applications. These, and many other questions which arise in the course of chemical investigation, involve as it were several distinct branches of enquiry, and lead us to contemplate chemistry under two points of view; namely, as an independent science, which embraces the whole field of chemical knowledge, and investigates the chemical relations of bodies without reference to any extraneous considerations—this is *pure, theoretical, or philosophical chemistry*; and secondly, as a science having certain objects in common with others, as with mineralogy, medicine, physiology, and the arts—this being *applied chemistry*.

In a subject, then, so extensive and complicated as chemistry, *systematic arrangement* is of the utmost importance to the teacher and student. In the broad principles of arrangement most writers agree; but in minor details each generally pursues a path of his own. It would be useless to enumerate the details of these arrangements as adopted by the leading didactic writers on chemistry; but the basis upon which they are founded deserves a few words of explanation.

The objects of chemistry are all included under one or other of the following heads; namely—

1. The general powers and properties of matter.
2. The chemistry of elementary substances.
3. The chemistry of compounds.

And each of these requires several subdivisions. Thus, under the first head, we include *attraction and affinity, heat, light, and electricity*; under the second head are included the chemical history and properties of the ponderable *elementary substances*, and their mutual *reactions*, which of course leads on to the third head; namely, to the chemical history and properties of *compound bodies*. To render the systematic arrangement of the elements and their compounds intelligible, it will be necessary to enumerate the former, and point out such of their characters as are connected with their classification.

train of enquiries, which can only be answered and worked out by multiplied *experiments*; for it is impossible to move onwards in this

CHEMISTRY

Every substance upon our globe contains one or more of the following *sixty-five* elementary or simple bodies: some of them are of extremely rare occurrence, others abundant and always with and about us. It will be observed that by far the greater number of them come under the denomination of *metals*; of the others, oxygen, hydrogen, carbon, and nitrogen are of much the most frequent occurrence, as will be obvious when it is recollected that air and water and all vegetable and animal products include two or more of the last-mentioned substances.

The equivalent or combining proportions of these elements, although mentioned under individual substances in this work, are here subjoined [AFFINITY; ATOMIC THEORY; and EQUIVALENTS], and also the *symbols* by which they are represented:—

Table of the Simple Substances, with their Symbols and Equivalent or Atomic Weights. (The non-metallic Elements are printed in italics.)

Elements	Symbols	Atomic Weights
1 Aluminium	Al.	14
2 Antimony (Stibium)	Sb.	129
3 Arsenic	As.	75
4 Barium	Ba.	69
5 Bismuth	Bi.	213
6 Boron	B.	11
7 Bromine	Br.	78
8 Cadmium	Cd.	56
9 Cæsium	Cæ.	123
10 Calcium	Ca.	20
11 Carbon	C.	6
12 Cerium	Ce.	46
13 Chlorine	Cl.	36
14 Chromium	Cr.	26
15 Cobalt	Co.	30
16 Columbium (Tantalum)	Ta.	184
17 Copper (Cuprum)	Cu.	32
18 Didymium	Di.	48
19 Erbium	Er.	?
20 Fluorine	F.	19
21 Glucinum	G.	7
22 Gold (Aurum)	Au.	197
23 Hydrogen	H.	1
24 Ilimenium	Il.	—
25 Iodine	I.	126
26 Iridium	Ir.	99
27 Iron (Ferrum)	Fe.	28
28 Lanthanum	La.	44
29 Lead (Plumbum)	Pb.	104
30 Lithium	Li.	7
31 Magnesium	Mg.	12
32 Manganese	Mn.	28
33 Mercury (Hydrargyrum)	Hg.	100
34 Molybdenum	Mo.	48
35 Nickel	Ni.	30
36 Niobium	Nb.	?
37 Nitrogen	N.	14
38 Norium	No.	?
39 Osmium	Os.	?
40 Oxygen	O.	8
41 Palladium	Pd.	64
42 Pelopium	Pe.	?
43 Phosphorus	P.	31
44 Platinum	Pt.	99
45 Potassium (Kallum)	K.	39
46 Rhodium	Rh.	52
47 Rubidium	Rb.	85
48 Ruthenium	Ru.	82
49 Selenium	Se.	40
50 Silicon	Si.	22
51 Silver (Argentum)	Ag.	108
52 Sodium (Natrium)	Na.	23
53 Strontium	Sr.	44
54 Sulphur	S.	16
55 Tellurium	Te.	64

Elements	Symbols	Atomic Weights
56 Terbium	Tb.	?
57 Thorium	Th.	60
58 Tin (Stannum)	Sn.	59
59 Titanium	Ti.	24
60 Tungsten (Wolfram)	W.	92
61 Uranium	U.	60
62 Vanadium	V.	68
63 Yttrium	Y.	32
64 Zinc	Zn.	32
65 Zirconium	Zr.	34

The examination of the physical and chemical properties of the preceding elements of matter leads us to classify them according to their analogies. The greater number of them possess the characters of *metals*. Several resemble the metals in certain respects, but are in others widely different; these therefore have been termed *metalloids*. A few are distinguished by entering into peculiar and distinct saline combinations, of which common salt may be taken as the type; these therefore have been termed *halogens*. And lastly, three of the elements are only known in the gaseous form; they have neither been liquefied nor solidified, but whenever they are isolated they present themselves as permanent gases; hence they have been designated *gasolytes*. This is the classification of the elementary bodies suggested by Berzelius, and it represents them as follows:—

I.	II.	III.	IV.
<i>Gasolytes</i>	<i>Halogens</i>	<i>Metalloids</i>	<i>Metals</i>
Oxygen.	Chlorine.	Sulphur.	
Hydrogen.	Iodine.	Phosphorus.	
Nitrogen.	Bromine.	Carbon.	
	Fluorine.	Boron.	

The metals, by far the most numerous of the elementary bodies, are themselves the subjects of various classifications, among which the following is perhaps the most convenient:—

Potassium.	Cerium.	Niobium.
Sodium.	Lanthanum.	Ilimenium.
Lithium.	Didymium.	Molybdenum.
Cæsium.		Uranium.
Rubidium.	Iron.	Tellurium.
	Manganese.	Titanium.
Barium.	Zinc.	Antimony.
Strontium.	Tin.	Arsenic.
Calcium.	Cadmium.	
Magnesium.	Copper.	Mercury.
	Lead.	Silver.
Aluminum.	Bismuth.	Gold.
Glucinum.	Cobalt.	Platinum.
Zirconium.	Nickel.	Palladium.
Thorium.	Chromium.	Rhodium.
Yttrium.	Vanadium.	Ruthenium.
erbium.	Tungsten.	Osmium.
Terbium.	Columbium.	Iridium.

Two which are but imperfectly known—namely, Norium and Pelopium are excluded from this list. Altogether, the number of metals known is 52.

The first five of the metals upon the above list are distinguished as the metals of the alkalis; their oxides are powerfully alkaline; they have an intense affinity for oxygen, and

decompose water at all temperatures. The next four metals are the bases of the alkaline earths; with the exception of magnesium, they also decompose water at all temperatures. The ten succeeding metals, with the exception of aluminium, have been but imperfectly examined; they are generally designated as the bases of the earths. The following twenty-two metals have been sometimes divided into those which form basic oxides, and those which form acids; and they have been separated into other distinctive groups, having reference to the action of acids upon them, to their action upon water at high temperatures, and to the isomorphism of their salts; these characters, however, are not sufficiently definite; and as regards the basic or the acid character of their compounds with oxygen, several of them form compounds belonging to both classes. The last nine metals have been particularly designated as noble metals; they are not changed by air or by water, and their affinity for oxygen is comparatively feeble: to some of these properties, however, osmium forms an exception.

In one or other, then, of these classes, each elementary body will find a place; but the arrangement only relates to the simple substances. The classification of their combinations, which are almost indefinite, is a much more intricate and difficult subject, and it would be impossible here to give even an outline of the different plans which have been pursued or suggested. As far, however, as the teacher of chemistry is concerned, none of the systematic arrangements of compounds can be conveniently adopted: his best plan, therefore, is to develop their history and properties as he proceeds. Having, for instance, discussed the abstract properties of oxygen and hydrogen, he proceeds to the compound which they form, and which is water; then he proceeds to the third element nitrogen, and its combinations with those previously described; thus, nitrogen and oxygen form five distinct compounds, namely, protoxide and binoxide of nitrogen, and hyponitrous, nitrous, and nitric acids. Nitrogen also combines with hydrogen to form ammonia, and ammonia combines with nitric acid to form the salt called nitrate of ammonia. In a state of mixture, nitrogen and oxygen constitute the great bulk of the atmosphere.

From this brief notice of the mode of dealing with the three elementary bodies of the first class, the reader will readily understand the method of applying the same principle to the entire list; the student will thus be conducted, step by step, from the simplest to the most complicated chemical combinations. It is generally convenient, however, in adopting this plan, to exclude the products of organisation, and to consider them apart, under a separate head, entitled *organic chemistry*, which is of course subdivided into the *chemistry of vegetable* and of *animal products*.

If, having studied chemistry upon this plan, we look back upon the path which has been traversed, we shall immediately see that the

compounds may be grouped into classes, related to each other by certain analogies both of properties and composition. Thus we have the class of *oxides*, or combinations of oxygen which are not acid; of *chlorides*, *iodides*, &c., and of *acids*; and these again subdivided into *oxyacids*, and *hydracids*; and lastly, the numerous class of *salts*, or compounds of the acids with salifiable bases.

When compound bodies are susceptible of electro-chemical decomposition (or *electrolytes*), the elements always tend to one or other pole; in other words, they are either separated at the point or surface at which the (presumed) electrical current enters, or at the surface at which it leaves the electrolyte; hence the arrangement of the elements into *electro-negative* bodies, or those which tend to the *anode*, and *electro-positive* bodies, or those which tend to the *cathode* (using the terms *anode* and *cathode* in reference to the ingress and egress of the electric influence); oxygen, the halogens, and sulphur are *anions*, or electro-negatives; hydrogen, and probably all the metals, are *cations*, or electro-positives. A good arrangement of the elementary bodies is founded upon such properties, although there are several whose electrical relations have not hitherto been accurately determined. [NOTATION, CHEMICAL.]

Chenocrocolite (Gr. *χην*, a goose; *κροκος*, dung; and *λίθος*, stone). An impure kind of Pitticite or Iron Sinter, containing a little silver and arsenate of cobalt. [GOOSE-DUNG SILVER.] It occurs in irregularly mammillated translucent masses of a yellowish-green or olive colour, in Cornwall, and at Allemont in Dauphiny; but chiefly at the mines of Clausthal in the Harz. It is a result of decomposition.

Chenopodiaceæ (Chenopodium, one of the genera). A natural order of monochlamydeous Exogens, distinguished with difficulty from *Anaranthaceæ* by their herbaceous calyx, and from *Phytolaccaceæ* by their solitary carpel, and the stamens never exceeding the number of the segments of the calyx, to which they are opposite. They consist of weeds inhabiting most parts of the world, abounding least within the tropics; and they possess few sensible properties. *Chenopodium anthelminticum* produces the Wormseed oil of the shops; but in consequence of their insipidity the species are often used for food, as in the case of spinach, &c. Chevalier has remarked the curious fact of *Chenopodium vulvaria* exhaling ammonia.

Cheque, Check or Draft. In Mercantile Law, is in legal effect an inland bill of exchange, drawn on a banker, payable on demand. It differs mainly from the latter in this, that the drawer of a check is not discharged by the holder's failure to present in due time, unless he have sustained from the delay actual prejudice, as by the failure of the banker. Much question having arisen as to the effect in law of the practice of crossing cheques, it was enacted in 1859 (21 & 22 Vict. c. 79, amending 19 & 20 Vict. c. 25), that a cheque crossed with the name of a banker should be paid only to that

CHEQUY

banker; and if crossed with the words 'and Company,' or any abbreviation thereof, then only to some banker.

Chequy, Cheeky or Chequered. In Heraldry, a term used when a field or charge is divided by transverse lines, paleways and fessways, into equal parts or squares of different tinctures.

Cherimoyer. The Peruvian name of the delicious fruit produced by *Anona Cherimolia*.

Cherophyllia. The poisonous principle of the *Cherophyllum sylvestre*, or Wild Chervil.

Cherry Coal. A soft Coal which resembles Caking Coal, but does not cake in burning. It requires little stirring, and gives out a cheerful flame and heat. The Staffordshire Coals principally belong to this variety, as do many of those of Glasgow, Derbyshire, &c.

Chersonesus. [PENINSULA.]

Chert. A siliceous mineral with many of the characters of Flint, but differing from it in being of a tougher nature, and in breaking with a splintery instead of a conchoidal fracture. It is of common occurrence in the Carboniferous Limestone of Derbyshire, Flintshire, and of the south of Ireland, as well as in the Upper Greensand of Dorsetshire. On Holywell mountain in Flintshire it is quarried for the purpose of paving the bed on which flints are ground, for the composition of the body of pottery. The Chert which occurs largely in the Mountain Limestone near Charleroi and Namur, has been worked for millstones.

Cherubim. [SERAPHIM.]

Chess. This is unquestionably a very ancient game; but of its early history, and of the origin of the name, nothing is known with certainty. The suitors of Penelope are mentioned in the *Odyssey* as amusing themselves with a game called *zestoi* (answering to the Latin *teserae*, or *squares*), which is also named by Herodotus (i. 94). But this game probably more resembled our draughts than chess. The Spanish name Xagüe, if it be a variation of Xequé, points to the Arabic sheik, or chieftain, which thus reappears in the French échec. The term *checkmate* is identified by some with the Persian *schah-mat*, *the king is dead*. But Sir William Jones, by a derivation which takes us back to the Greek *chétrapes* and Latin *teserae*, ascribes the invention of the game to the Hindus, by whom it is called *chaturanga*, i.e. the four *angas*, or members of the army—elephants, horses, foot soldiers, and chariots. This word was, he thinks, changed by the Persians into *chetrang*, and further altered by the Arabs into *shetrang*, and thence by successive changes has become *axidrez*, *scacchi*, *échecs*, *chess*, 'and by a whimsical concurrence of circumstances has given birth to the English word *check*, and even a name to the *archbishop* of Great Britain.'

The game, which has undergone many modifications, is now played by two persons, with thirty-two pieces called *men*, on a square board divided into sixty-four equal squares, black (or red) and white alternately. Each player, there-

CHESSYLITE

fore, has sixteen men, distinguished by their colour—those of one side being black (or red); of the other, white. The rows of squares which run from one player to the other are called files; those from side to side being known as ranks, or lines; while those which run obliquely are called diagonals, each diagonal necessarily consisting wholly either of black or white squares. The board is so placed that each player has a white corner at his right hand. The eight *pieces*, as distinguished from the eight pawns, consist of a king and queen, two castles or rooks, two bishops, and two knights, and are all placed on the rank nearest the player to whom they belong. Of these, the two rooks or castles occupy the two squares forming the angles of the board. The two knights occupy the squares next to the rooks, the two bishops being next to the knights, while the king and queen have each one of the two middle squares, the queen being on a square of her own colour. The pawns occupy the lines immediately in front of the pieces, and are named after the several pieces before which they are respectively placed, as king's pawn, queen's pawn, &c. The pawn moves straight forward on its own files; but captures its adversary obliquely or diagonally. The knight moves by leaping obliquely over an adjoining square to one of the next squares, of a different colour from that which it leaves. The bishop moves diagonally forward or backward, over any number of squares at one time, if the course be open. The castle or rook moves straight forward, or backward, or sideways any number of squares at a time, provided these are unoccupied by other men. The queen can move either like a castle or a bishop, while the king moves only one square at a time, in any direction. When an attack is made upon a king by any piece or pawn, he is said to be in *check*.

The object of the game is to give *checkmate*, which takes place when the king is so beset that he can neither move out of check, nor take the piece or pawn that checks him, nor interpose any piece for his protection. *Stalemate* occurs when the king is not in check, but yet cannot move without going into check, all his men being at the same time off the board, or so placed that none of them can move; in such the game is held to be drawn. It is also a drawn game when neither party can give checkmate to the other.

The first practical book on chess is the *Repetición de Amores* of Ramirez de Lucena, printed probably at Salamanca about 1495. Caxton, in his *Game and Play of the Chess*, merely moralises on the game. The subject is elaborately treated in Staunton's *Handbook of Chess*.

Chessylite or Chessy Copper. Blue carbonate of copper. It is composed of 25.43 per cent. of carbonic acid, 69.37 oxide of copper, and 5.20 water; and, when pure, contains 55.16 per cent. of copper. Earthy varieties are of a small-blue colour, but when crystallised it is of

CHEVALIER

a beautiful azure-blue with a vitreous lustre, and varying from transparent to opaque. It occurs less frequently than Malachite, in the same localities, and, like it, is the result of the decomposition of other ores of copper (Grey Copper, Red Copper, &c.), with which it is associated. When in sufficient quantity, it constitutes a valuable ore of copper. The name Chersylite is derived from that of the locality, Chessy, near Lyons, where the mineral is met with abundantly, in very beautiful crystals, and also in a fibrous state.

Chevalier (Fr. from cheval, a horse). Is used synonymously with the Eng. knight, Lat. aques, and Ger. ritter.

Chevaux de Frise (Fr.). Large and strong pieces of timber, traversed with wooden spikes pointed with iron. Sometimes they are made entirely of iron. They are used as an obstacle to impede the advance of troops.

Chevrette. In Artillery, an engine used for raising guns or mortars into their carriages.

Chevron (Fr.). In Heraldry, one of the nine honourable ordinaries. It may be defined as consisting of the lower half of a saltire [SALTIRE], brought to a point on the upper side. The object from which its name is derived accurately resembles it in shape; chevron, in old French, meaning the support of a roof formed by two rafters leaning against one another. A chevron standing on one side of the escutcheon is said to be touny, dexter, or sinister. A Chevronel is an ordinary of the same shape with the chevron, but containing only half its dimensions.

Chevrons. The stripes worn on the arm by a non-commissioned officer in the army to distinguish his rank. A staff-sergeant wears four, a sergeant three, a corporal two, and a lance-corporal or bombardier one chevron.

Chios Turpentine. A species of turpentine brought originally from the island of Chios: it is the produce of the *Pistacia Terebinthus*.

Chiaro-scuro (1 al. clear-obscure, literally light-dark). In Painting, the art of disposing the lights, both positive and reflected, and the shadows of a picture, in such a manner that the objects may stand out and be naturally relieved from one another. It means the mutual relation between light and dark masses. Its name, however, seems more naturally to point to those parts of represented objects which, though in shadow, have the intensity of such shadow lessened by the reflection of a light body against them. It is a branch of Sciography, and Rembrandt is one of the most illustrious masters in the art.

Chiasolite. Malle or Hollow Spar. A variety of Andalusite found embedded most frequently in clay-slate, but sometimes in mica-schist. It occurs in the slate of Cumberland and of Wicklow, in the Pyrenees, &c. It is always crystallised, and the crystals are in the form of rhombic prisms which are externally greyish-white, and present internally a black or bluish-black cross in their transverse section. This appearance is produced by prisms

CHIEF

of a darker substance in the centre, and sometimes at each angle, connected by thin plates of the same, consisting sometimes of a carbonaceous substance and sometimes of clay-slate. The name Chiasolite was given to this mineral from the circumstance of the dark lines on the sections of the crystals resembling the Greek letter chi: hence the term, from *χιασμός*, marked with a χ.

Chica. A red colouring matter used by some tribes of American Indians of the Orinoco and Rio Negro to stain the skin; it is extracted from *Bignonia Chica*.

Chicken-pox (*Varicella* of medical writers). An eruptive disease, which, though frequently very mild in its attack, is often also violent and attended by much fever. The eruption consists of smooth vesicles of various sizes, which afterwards become whitish and straw-coloured; about the fourth day they break and scab off, seldom leaving marks, or at least not more than a few, upon the most delicate parts of the face, or where they happen to have been large or accidentally scratched or irritated. In very warm weather the fluid in the vesicles becomes yellow, and apparently purulent, so as closely to resemble small-pox in appearance; and under some circumstances, the eruptive fever has been not only considerable, but preceded by delirium. The distinctive or diagnostic characters by which we distinguish chicken-pox from small-pox are: 1st. The comparative mildness of the preliminary fever, which indeed is often unobserved in strong and merry children, nothing being known of the complaint till spots are observed about the face and breast. 2nd. The rapidity with which the eruption attains maturity and proceeds through its stages, the scabs forming crusts about the fourth or fifth day, which does not happen in the small-pox till the tenth or eleventh. 3rd. The fluid in the vesicles is usually transparent, or only milky, whereas in small-pox it has a purulent appearance from the commencement. Like the small-pox, it very rarely attacks the same individual more than once. In the treatment of this disease little else is in most cases requisite than to keep the patient cool, to abstain from meat, to give diluents and mild aperients, and occasionally, at the commencement, a dose of calomel and rhubarb. In bad cases, the whole body is covered with eruption, but in mild ones there will only be a very few vesicles; and it not uncommonly happens that where several children have it in succession, one or two will escape with little else than slight restlessness and very trivial febrile symptoms. It is, however, by no means so trifling a disease as many writers have represented it, and if not closely watched over may be mistaken for small-pox.

Chief (Fr. chef, head). In Heraldry, the upper part of the escutcheon, divided into three points, dexter, middle, and sinister. A chief, as an ordinary, is a fess removed to the upper part of the escutcheon. Charges, in the situation of the chief, are described as 'in chief.'

CHILBLAIN

Chilblain. An inflammatory swelling, of a purplish colour, produced by exposure of the extremities to cold: it is generally attended with itching and often shooting pains. Children, especially those of a scrofulous habit, and old persons, suffer most from chilblains; but they are not unfrequently produced at all times by holding the hands or feet to the fire after they have been exposed to great cold; in which case, the difference of temperature is such as actually to burn the part, for few persons are aware of the high temperature excited by the radiant heat of a common fire upon substances held near it. Warm socks and gloves are the best preventives against this affection, and the itching and pain are generally relieved by moderately stimulating applications, such as equal parts of solution of acetate of ammonia or of vinegar and spirits of wine, or of oil of turpentine and soap liniment. If the part should break or ulcerate, stimulating dressings, such as the resin or elemi ointment, are most serviceable, or in some cases mild escharotics.

Child-bishop. [BOY-BISHOP.]

Childrenite. A hydrated phosphate of alumina and iron with more or less protoxide of manganese, magnesia, &c. It has been found in Cornwall, in yellow or brownish-yellow crystals or crystalline coatings on Sparry Iron, Pyrites or Quartz, at Crinnis Mine near St. Austell, at the George and Charlotte Mine, and at Huel Crebor.

Named after the late Mr. Children, of the British Museum.

Chileite. The name given by Keugott to a vanadate of lead and copper found at Mina Grande in Chili, where it occurs in cavities in arseno-phosphate of lead with amorphous carbonates of lead and copper. It has a dark-brown or brownish-black colour, and an earthy appearance like that of a ferruginous clay or earth.

Chiliad (Gr. χιλιάς, *a thousand*). An assemblage of things grouped or ranged by thousands. The word is chiefly used by the early computers of logarithmic tables, who expressed the extent of the table by saying it contained the logarithms of so many *chiliads* of absolute numbers.

Chilists (Gr. χιλισταί). In Ecclesiastical History, believers in the second advent of Christ to reign a thousand years on earth. [MILLENNIUM.]

Chilognathes, Chilognatha (Gr. χείλος, *a lip*, and γνάθος, *a jaw*). An order of the class *Myriapoda* or *Centipedes*, in which the two mandibles and the tongue are united together to form a large lower lip.

Chiloma. In Zoology, the upper lip or muzzle of a quadruped is so called when it is tumid, and continued uninterruptedly from the nostril, as in the camel.

Chilopoda, Chilopoda (Gr. χείλος, and ποῦς, *a foot*). An order of the class *Myriapoda* or *Centipedes*, in which the lower lip is formed by a pair of feet.

CHIMNEY

Chiltern Hundreds. In Politics. The tract anciently called the Chiltern Hundreds extends through part of Buckingham and Oxford shires. The steward of these hundreds was an officer appointed by the crown to keep the peace there. As members of parliament, strictly speaking, cannot resign their seats, the mode of abandoning them is by accepting a nominal office (such as this stewardship) under the crown, which vacates the seat of the party taking it.

Chimæra (Lat. ; Gr. χίμαιρα). In Ichthyology, the name of a genus of Branchiostegous cartilaginous fishes; the best known species, which inhabits the northern seas, and has occasionally been taken on our own coast, is sometimes called 'king of the herrings.'

CHIMÆRA. In Mythology, is described in the *Iliad* (vi. 181) as having the head of a lion, the body of a goat, and the tail of a dragon. Many different forms are, however, assigned to it by other poets; and the word, in nearly all the modern languages of Europe, has come to mean any wild or incongruous fancy arising in the mind.

Chimaphila (Gr. χείμα, *winter*, and φιλέω, *to love*). A genus of *Pyrolaceæ*, called Wintergreen in North America, where it is valued for its tonic and stomachic properties. The leaves are bitter-sweet.

Chimney (Fr. cheminée, Lat. caminus). The place in a room where the fire is burnt, and from which the smoke is carried away by means of a flue. That part of the opening which faces the room is properly the *fireplace*, the stone or marble under which is called the *hearth*, that on a level with the hearth is called the *slab*; the vertical sides of the opening are called the *jamb*s; the head of the fireplace is called the *mantle*; and the cavity, or hollow, from the fireplace to the outlet, is called the *funnel*. The part of the funnel which contracts as it ascends is termed the *gathering*, or by some it is called the *gathering of the wings*. The tube or cavity, usually of a parallelogrammatic form in plan, from the point where the gathering ceases up to the top of the chimney, is specifically called the *flue*, and the part between the gathering and the flue is called the *throat*. The part of the wall facing the room, and forming one side of the funnel parallel thereto, or the part of the wall forming the sides of the funnel, where there is more than one, is the *breast*. In external walls the side of the funnels opposite the breast is called the *back*. When there is more than one chimney in the same wall, the solid parts that divide them are called *parties*; and when several of such chimneys are collected into one mass, it is called a *stack of chimneys*. The part which rises above the roof for discharging the smoke into the air, is called a *chimney shaft*, whose horizontal upper surface is called the *chimney top*. The coverings or the linings of the jamb used formerly to be placed at right angles to the face of the wall; but Count Rumford showed that by inclining them, the heat was increased by the quantity reflected

CHIMNEY STALK

from their surface. He also taught builders to place the fire as near the hearth as possible, and he showed the advantage of contracting the funnel as much as possible. Generally speaking, flues are made 9 inches wide by 14 inches long; but these dimensions were adopted for the convenience of the climbing boys, who could not ascend in less dimensions; there seems to be no reason, now that the machine is used, for retaining them, and it certainly would be better to make them 9 inches square, for the generality of fireplaces at least. [FIREPLACE; GRATE; STOVE.]

Chimney Stalk. This word is usually applied to a lofty chimney, such as are erected for steam-engines. It is recommended that the dimensions of them should be as follows (*Civil Engineer Journal*, xviii. 319):—

	Diam. at top, inside.	Nominal horse- power.
Yds. high.	ft. in.	h.-p. of boiler.
20	1 6	10
25	1 8	12
30	1 10	16
33	2 0	20
35	2 6	30
40	3 0 to 4 ft.	50 to 90
45	4 6	120
50	5 0	160
55	5 6	200
60	6 0	250

Chimpanzee, Chimpanse or Quimpese.

Native names of the African orang (*Troglodytes niger*, Geoff.). It is of a black colour, and attains the height of between four and five feet, measured in a straight line from the vertex to the heel. For many years the osteological evidences of the structure of this animal, as well as the proofs of the habits and manners of the adult, were unknown to British readers, who were only acquainted with it from observation of the young specimens. It differs from the Asiatic or Red Orang not only in colour, but in the greater size of the external ears, the more prominent supraorbital ridge, the relative shortness of the arms, and the greater development of the thumb of the hind foot, which has constantly two phalanges and a nail. The principal osteological differences between the genera *Troglodytes* and *Pithecus* are the following: The cranium is flatter and broader in proportion to the face. The supraciliary ridges are more developed; and the great interparietal and lambdoid crests, which render so remarkable the skull of the adult orang, are in the chimpanzee wanting. The interorbital space is broader. The occipital foramen has a more central position. The anterior condyloid foramen is single on each side, while in the orang it is double. The intermaxillary sutures are obliterated before the deciduous incisors are shed. The incisive and canine teeth are of smaller proportional size. There are thirteen pairs of ribs instead of twelve pairs, as in the orang; and consequently there are thirteen dorsal vertebrae. The sternal bones form a single row.

CHINCHILLA.

The chimpanzee further differs from the orang-utan in the non-division of the pisiform bone of the wrist; and in the depression at the head of the femur, corresponding to the interarticular ligament of the hip-joint, which is wanting in the orang.

The habits and deportment of the chimpanzee, as observed in those young specimens which have been brought alive to this country, are of peculiar interest, from the high degree in which inquisitiveness, perception, memory, and docility are manifested; and by the gravity and consideration with which many even of its ludicrous and playful actions are performed. It is probable, however, that in the adult much of this intelligence gives way to the fiercer traits of the brute nature.

We have also had evidence of a larger species of *Troglodytes*, the GORILLA [which see].

China Clay or Kaolin (*Pr-tun-tse* is the name of a variety). A clay used in manufacturing porcelain. *China stone* is also a material used in the manufacture of porcelain, and nearly of the same nature. Large quantities of china clay and china stone are obtained from Cornwall and Devonshire for the use of the English potteries. The *china stone* is a partially decomposed granite covering the surface of much of the middle of Cornwall. It consists of the felspar crystals partly broken up and mixed with a quantity of silica. This material is calcined and ground before exportation. *China clay* is the more completely disintegrated felspar reduced to a state of fine division, and separated by washing from the coarser particles and sand with which china stone is mixed up. When mechanically separated from impurities, it is bleached by sun and air and dried into bricks about a foot cube, which are exported to the potteries. From some of the deposits the natural clay is sufficiently pure to be exported at once. About 14,000 tons of prepared and 30,000 tons of natural china clay were sent some years ago from one district. The composition of *kaolins* varies greatly. [KAOLIN.]

The china clays of France and Germany, used in the celebrated manufactories at Sèvres and Dresden, are obtained from the granite districts of those countries, as doubtless is the case with China and Japan, where hard china of the finest kind has been made from time immemorial.

China Ink. A finely divided carbon, probably lampblack of some kind, mixed with gelatine, and formed into cakes or sticks. It is sometimes stated to be the desiccated ink of the cuttle-fish.

China Root. The root of the *Smilax China*, so called because imported from China. It was formerly used in the same cases in which sarsaparilla is now given.

Chinchilla. The generic appellation founded on the South American or local name 'chinchille,' or 'little chincbe,' and applied to a genus of gnawing Mammalia or Rodents peculiar to the South American continent. It

CHINESE ARCHITECTURE

is from a species of this genus (*Chinchilla lanigera*) that the grey fur is obtained which has been so much prized in Europe for many years; but the exact nature of the animal itself has been only very recently ascertained, by the examination of specimens which have been procured for the menagerie of the Zoological Society.

Chinese Architecture. [ARCHITECTURE, CHINESE.]

Chinese Swallows' Nests. These curious productions were formerly supposed to have been made of some kinds of seaweed, as *Sphaerococcus lichenoides*; but they are ascertained to be formed of a secretion from the mouth of the bird itself.

Cinchonidine. *Quinoidine, Cinchoidine.* Uncrystallisable cinchona alkaloids, resulting from the action of heat in drying cinchona bark and in extracting the active principles. It also contains colouring matter and resin.

Cinchonine. *Quinoline, Cincholine, Leucole, Leuconine.* An oily volatile alkaloid, derived from the cinchona alkaloids by distillation with caustic potash.

Chinone. A substance obtained by distilling certain salts containing kinic (cinchonic) acid, as for instance the kinate of lime, with oxide of manganese and sulphuric acid. Chinone sublimes in the form of golden-coloured crystals, soluble in water, very volatile, and of a very peculiar and distinctive odour. Their formula is said to be $C_{12}H_6O_2$.

Chinovic Acid. *Quinovic or Quinovatic or Kinovic Acid.* An acid occurring in small quantity in cinchona bark.

Chintz. A peculiar pattern upon printed calicoes, in which flowers and other devices are printed in five or six different colours, upon white and coloured grounds. A good chintz pattern in fast colours is one of the most surprising and difficult efforts of the art.

Chinoocetic Acid. *Chinoocetic* is the botanical name of caica root. It appears to be identical with *cinovetic acid*. [CAINIC ACID.]

Chiolite. A fluoride of sodium and aluminium forming a vein in graphitic granite at Misak in the Ural. It sometimes is found in octahedral crystals, but generally compact like Cryolite, with a crystalline structure, snow-white, and with a vitreous lustre.

Chitp. A material obtained from the leaves of the palm called *Thrinax argentea*, and used for plaiting into hats and other articles of utility or ornament.

Chiragra (Gr. *χρηδρα*). Gout in the hands.

Chirata or Chiretta. The Indian tonic *Agathotes Chirata*.

Chirograph (Gr. *χειρογραφος*, written with the hand). In Diplomacy, a species of instrument contrived for the purpose for which indentures were devised; viz. the enabling different parties to retain authenticated counterparts of the deed. Some word (commonly the word *chirographum*, whence the name) was written between the two copies on the same

CHIVALRY

sheet, and cut through lengthwise when they were divided.

Chirolgy (Gr. *χολη*, the hand, and *λογος*, discourse). The language of the fingers; sometimes called *dactylology*, from *δακτυλος*, the finger.

Chiromancy or Palmistry (Gr. *χειρομαντεία*). The imaginary art of divination by the lines of the hand. According to the science of Chiromancy, the lines on the palm of the hand are divided into principal and inferior; the former are five—the line of life; the line of the liver or natural mean; the line of the brain; the thoral line, or line of fortune; the dragon's tail, or discriminal line, between the hand and the arm. Various other modes of divination were practised by observation of the hand and its parts; onychomancy (from *onyx*, a nail), dactylomancy (from the fingers), &c. The practice of chiromancy, once defended and explained by grave and learned authors, is now chiefly left to be exercised by the gipsies.

Chiromomy (Gr. *χειρονομία*). The science which treats of the rules of gesticulation, or pantomime and oratorical action.

Chisel (Ital. *ciello*; Fr. *ciseau*). The name given to some kinds of tools having a cutting edge at the base of a metal blade, and bearing an upper portion adapted to receive an impulse either from the hand or a hammer. The use of these instruments is of great antiquity, as the Egyptians used those made of bronze; and the occurrence of flint implements of this kind proves that they were well known in the very earliest periods of civilisation.

Chitine. The hard insoluble matter forming the shells and elytra of insects.

Chiton (Gr. *χιτών*). The name of a genus of Gastropodous Molluscs, which have a series of testaceous symmetrical pieces implanted in the back part of the mantle.

Chivalry (Fr. *chevalerie*). The usages and customs pertaining to the order of knighthood. The general system of manners and tone of sentiments which the institution of knighthood, strictly pursued, was calculated to produce, and did in part produce, during the middle ages in Europe, is comprehended in ordinary language under the term of *chivalry*. This imaginary institution of chivalry, such as it is represented in the old romances, had assuredly no full existence at any period in the usages of actual life.

The origin of chivalry has often been traced to the German tribes; nor has its spirit ever penetrated very deeply into the usages of any country in which these tribes have not either produced the ancestors of the great body of the nation, or at least the conquering and governing class, which transfused its habits and sentiments into that body. Thus Germany and France, and England, whose gentry derive their origin from both, have been the countries most distinguished for the prevalence of this institution. The martial spirit of the Spaniards was indeed partly animated by it; but in their country it always bore something of the cha-

CHIVALRY

acter of a foreign importation, modified by the circumstances of their juxtaposition with the Arab race. In Italy, it existed only among those classes which imitated the manners of France and Germany, and never entered into the general character of the natives, notwithstanding the popularity of the poetical romances of chivalry. Among the Slavonic nations it has never prevailed extensively; although the feudal constitution of Polish society derived a certain tincture from it, it never penetrated into Russia. It has been often remarked, that it is only within the last two or three generations that the nobility of that country, by their intercourse with the nations of Western Europe, have derived something of the spirit of the chivalrous code, so far as it still subsists among ourselves. The point of honour, and its peculiar concomitant the usage of the duel, were scarcely known in Russia before the present century.

Chivalry originated in the feudal attachment of warriors to the person of their king or chief, which has been so often described as characteristic of the ancient Germans. Hence the English word *knights*, which, when the Norman 'chevaliers' were first known among us, was spontaneously used as the translation of their title, signified originally a servant or attendant. At what precise time the devotional character was added to the original martial impress of national usages, and the compound system of chivalry was thus produced, it is not easy to ascertain. It has been said that the investiture of the knight was purely military until the reign of Charlemagne; and it may be supposed that the wars of the Franks against the Saracens first blended the ardour of war and religion together, and that the Crusades completed the union. At the latter period were instituted the two celebrated military orders of monks, the *TEMPLARS* and *HOSPITALIERS* [which see], the code of whose government combined monastic and knightly usages. After valour and devotion, the third characteristic feature of chivalry was gallantry to the fair sex; and the source of this sentiment also has been traced to the habits and feelings of the Northern tribes, among whom woman was looked on with a much more exalted sense of her dignity than in the most civilised countries of antiquity. It is needless to add, that this romantic feeling, however high its precepts may have sounded in theory, degenerated into licentiousness in actual life. M. de Sainte-Palaye, the learned French historian of the usages of chivalry, has brought instances enough to prove the extreme depravation of manners which prevailed, even in those courts and at those periods in which the spirit of chivalry was most prevalent. If the Crusades communicated to chivalry its devotional character, it is in the poetry of the Troubadours about the same period, in the twelfth and thirteenth centuries, that we find its peculiarity of devotion to the female sex first developed. But in their verses it does not appear clothed with the romantic purity with which it was afterwards invested

by the writers of the heroic tales of chivalry, and still less in those of the contemporary French writers of the *Fabliaux*, from whose compositions we draw the most authentic monuments which we possess in this curious branch of antiquarian research. The knight, or even the esquire, was bound to follow a single lady and dedicate himself to her service; but little delicacy is either intimated or enjoined in the relations which subsisted between them, and his devotion to her was considered as entitling him to every recompense love could bestow.

The fourteenth century was the brilliant period of chivalry, when its usages, originally formed in the manners of the people, had become fixed and embellished by the fictions of the writers of romances; and when princes and chieftains, forming their idea of the institution rather from the descriptions contained in them than from real life, sought to bring back their courts and camps to the likeness of those ideal models of perfection. It may be more truly said that the romances of chivalry were the prototypes of that state of courtly society which existed in the reigns of our Edward III. and Richard II., and of which Froissart has left us such accurate and lively representations, than that existing manners and sentiments furnished the subject-matter of those romances. These fictions, of which the heroes were taken from among a long list of fanciful personages, in whose history a little tradition of past events was blended with a much larger proportion of fable, represented the knight not only as devoted to the service of his religion, his lord, and his mistress, but also as consecrated to the general service of the oppressed, and to the maintenance of right all over the world. There can be little doubt that the peculiar ceremonies which in the fourteenth and fifteenth centuries accompanied the creation of a knight—the vow of chivalry, the watching, prayer, and fasting, &c.—were borrowed by romantic imaginations from such fabulous recitals, which were read and related in every courtly company. Before that period, the manners of the knights and dames had exhibited but little of that polish and refinement, their sentiments but little of that generosity, which were the subjects of so much imaginary description; and, in later times, chivalry gradually decayed. Its usages were maintained with even more of magnificence than before; its various rites, titles, and distinctions subsisted for a long period in most European countries, and partly remain to this day; but the spirit of feudal devotedness was quenched by the multiplication of mercenary troops; adherence to a feudal lord was superseded by the more general feelings of national patriotism (which was almost wholly omitted in the chivalric code), and the extravagances into which the imaginary point of honour had led its votaries, fell into discredit and ridicule.

It is, therefore, to the fourteenth century, and especially to that part of its chronicles preserved by the true annalist of chivalry, Froissart,

that we must look for the period when the line between real society and that represented in romances was most nearly broken down. When the usages of chivalry were most flourishing, all men of noble birth (except the highest) were supposed to pass through three orders or gradations. They first lived as pages in the train of nobles and chiefs of high rank; next, as esquires, they attached themselves to the person of some individual knight, to whom they were bound by a strict law of obedience, and for whom they were bound to incur every danger, and, if necessary, sacrifice their lives; and, thirdly, they were promoted to the rank of knighthood. (For the different orders of knighthood, see KNIGHT.) It is sufficient to observe here, that however great the distinction might be between knights in point of rank and wealth, custom established a species of equality among all of the same order, which may be said to subsist among gentlemen of the present day. They formed, all over Europe, a common corporation, as it were, possessing certain rights, and owing each other certain mutual duties and forbearances. They were united, not by the ties of country, but by those of feudal obedience, which attached every knight to the banner of his liege lord, from whom he held his fee; but little or rather no dishonour attached to knights who were under no such feudal tie, if they chose their own chieftain wherever they thought fit: they were free adventurers, whose order was a passport in every service; and, in the actual conflict, the hostility of knights was moderated by usage. Thus, it was dishonourable in any knight to take a knight's life if disarmed, and not to set him free when a prisoner on receiving a fitting ransom. Manny and Chandos, the two most celebrated knights of Edward III., were attached wholly to the banner of their sovereign, and not to that of their country; and although the French constable Duguesclin, the third among these mirrors of chivalry, appears to have been devoted to the cause of France as well as to that of his master, this double loyalty found few imitators. In peace, also, knights of all countries were welcome visitors at the courts of chivalric sovereigns; and all enjoyed the privilege of presenting themselves at the tournament, and contending there for the prize.

With regard to the point of honour, which forms the most important feature in the usages of chivalry, see some details under the article DUEL. The principal objects to which it related were: religious belief; fealty to the feudal superior; devotion to some one selected lady; and, finally, the general character for honour and courtesy which it was incumbent on a knight to maintain; for although his imaginary duties, as a knight-errant, to avenge wrong and succour the oppressed on every occasion, were not of course very strictly put in practice, yet his vow to perform those duties attached to his character a certain degree of sacredness which it was necessary to maintain. Chivalrous honour was chiefly supported in two ways: first, by

the single combat or duel, whether on account of serious provocation or by way of trial of strength; secondly, by the performance of vows, often of the most frivolous and extravagant nature. These were generally undertaken for the honour of the ladies. Many historical instances of these absurd yet daring follies are recorded by Froissart; and with other usages of knighthood, they were long preserved among those who aimed at the reputation of chivalry, after these usages had ceased to form a part of the ordinary customs of society. Thus, the instances which Froissart relates of knights riding alone up to the barriers of fenced cities, &c., were imitated in after-times, and at no less personal hazard, by such romantic personages as Lord Herbert of Cherbury, whose feats, performed in rivalry with the French champion Balagny, are mentioned in his Memoirs. But the vows related not only to martial achievements, but to others of a more extravagant and grotesque character. We need only refer to Monstrelet's narrative of the company called 'Galois' of knights and ladies, who bound themselves, for love of each other, to follow a particular code of usages; of which a part consisted in wearing thick clothes in summer and thin in winter, to show that the power of their love rendered them insensible to the difference of seasons; a vow which was maintained with such perseverance, that the greater part of the devoted company actually died of cold. (See also the *History of the Vow of the Heron*, Sainte-Palaye, vol. iii.) The commencement of such extravagances, however, betokened the decline of the true spirit of chivalry. It decayed with the progress of mercenary armies and the decline of feudal institutions through the fifteenth century; in the sixteenth, it was little more than a lively recollection of past ages, which knights such as Bayard and sovereigns such as Francis I. and Henry VIII. strove to revive; and, finally, it became extinguished amid religious discords, leaving as its only relic the code of honour, which is still considered as governing the conduct of the gentleman.

Chiviatite. A lead-grey coloured mineral resembling Bismuth Glance, found in foliated masses with Pyrites and Heavy Spar at Chiviate in Peru. It is a sulphide of bismuth, lead, copper, iron, &c.

Chladnite. A mineral found in a meteoric stone which fell at Bishopville in North America, and named after Chladni; it is a tersilicate of magnesia.

Chlamyphore, Chlamyphorus (Gr. *χλαμύς*, a cloak, and *φέρω*, I carry). A name given to a small species of Armadillo, which is covered by its coat of mail as by a cloak. The animal is not above six inches long, and, like the rest of its genus, inhabits exclusively the continent of South America. In its habits it is said to resemble the mole. It is interesting from the analogy of its skeleton and coat of mail to those of the gigantic extinct megatherium.

CHLENACEÆ

Chlenaceæ (Gr. *χλαῖνα*, a cloak: all the names of genera belonging to this order are compounded of this word, used in a figurative sense for an involucre). A natural order of shrubby or arborescent Exogens, allied to *Malvaceæ*, on account of their monadelphous stamens and involucre flowers, but referred by Jussieu to the vicinity of *Ebenaceæ*. Their imbricated calyx, regular flowers, and abundant albumen has induced Lindley to place them in his Gerania alliance. Hooker and Bentham, however, place them at the end of their Guttiferal alliance, near to *Malvaceæ*. They are all natives of Madagascar, beautiful in their flowers, but of no known use.

Chlor-iodoform. A heavy yellow aromatic liquid derived from chloroform by the introduction of one equivalent of iodine in the place of chlorine.

Chloroacetic Acid. A crystalline acid obtained by the action of the solar rays upon a mixture of chlorine with the vapour of acetic acid. Its formula is $C_2Cl_3O_2, H\ O$; in it, therefore, the hydrogen of the acetic acid is replaced by chlorine.

Chloral (a word made up of the first syllables of *chlorine* and *alcohol*). A liquid composed of chlorine, carbon, hydrogen, and oxygen, obtained by the action of chlorine upon absolute alcohol. Its formula is $C_2H_2O_2Cl_2$.

Chloramylal. A liquid derived from amylic alcohol by the action of chlorine.

Chloranthaceæ (Chloranthus, one of the genera). A small natural order of apetalous Exogens, nearly allied to *Saururaceæ* and *Piperaceæ*, from both of which it differs in wanting a sac to the embryo, and in having a pendulous ovule and opposite leaves with intermediate stipules. They are natives of the hotter parts of the world, and appear to possess stimulating properties of great importance. *Chloranthus officinalis* and *brachystachys*, although not officinal in Europe, are powerful stimulating agents.

Chlorapatite (Gr. *χλωπός*, green, and Apatite). A variety of Apatite from Kragerøe in Norway, distinguished by the absence of fluorine, and the presence of a small variable quantity of chloride of calcium.

Chlorastrolite (Gr. *χλωπός*; *ἄστρον*, a star; and *λίθος*, stone). A pale bluish-green mineral found on the shores of Isle Royale, Lake Superior, in small rounded waterworn pebbles, which have been derived from trap rock. It is finely radiated or stellate in structure, with a pearly lustre, and is chatoyant at the rounded sides. It is a hydrated silicate of alumina, iron, lime, and soda.

Chlorates. Combinations of chloric acid with salifiable bases. Of these salts the *chlorate of potash* is best known; it was formerly called *oxymuriate of potash*. When mixed with combustibles, such as sulphur or charcoal, and some of the metals, it forms highly explosive compounds, which ignite by a blow or by friction, or upon the contact of sulphuric acid. A mixture of this salt with

CHLORINE

sugar, or with sulphuret of antimony, was used in tipping the *matches* which inflame when dipped into sulphuric acid, but which are now superseded by mixtures containing phosphorus, which are inflamed by simple friction. Chlorate of potash consists of 76 chloric acid + 48 potassa = 124 of the chlorate.

Chlorazol. An acid poisonous pungent liquid resulting from the action of nitrohydrochloric acid on albumen.

Chlorhydric Acid. [HYDROCHLORIC.]

Chlorhydrines. Oily liquids derived from glycerine by the action of varying quantities of hydrochloric acid.

Chloric Acid. A compound of 1 atom of chlorine with 5 of oxygen, represented therefore by the formula ClO_5 . Its most important salt is the chlorate of potash.

Chlorides. Combinations of chlorine, corresponding to the oxides. Common salt is a *chloride of sodium*; that is, a binary compound of chlorine and sodium. Where there are two chlorides of the same base, the relative proportions of chlorine in them are almost invariably as 1 to 2; hence the terms *protochloride* and *bichloride*.

Chlorimetry. The estimation of the available chlorine in any bleaching compound of that element. There are several chlorimetric processes, but that of Dalton is the most convenient. To a known quantity of protosulphate of iron acidified with hydrochloric acid, the bleaching compound is added until the iron is all peroxidised. As the quantity of chlorine necessary to do this can be calculated, the value of the sample is easily ascertained from the weight of it used in the process. The richer the specimen, the less of it will be required.

Chlorine (Gr. *χλωπός*, pale-green). Chlorine was discovered in 1774 by Scheele, who called it *dephlogisticated muriatic acid*; the French nomenclaturists afterwards termed it *oxygenated muriatic acid*, conceiving it to be a compound of oxygen and muriatic acid. This erroneous view of its nature was corrected in 1809 by Sir H. Davy, who gave it the present name, indicative of its colour. Chlorine is a simple substance, existing at common temperatures and pressures in the gaseous state; but when subjected to a pressure of about four atmospheres it becomes condensed into a yellow transparent liquid, which is a non-conductor of electricity. 100 cubical inches of chlorine, at mean temperature and pressure, weigh between 76 and 77 grains: water absorbs twice its volume, and acquires a yellow colour, and the peculiar suffocating odour of the gas. When humid chlorine is exposed to a temperature of 32°, it assumes a crystalline form; this *hydrate of chlorine* consists of 1 equivalent of chlorine = 30 + 10 of water = 9 × 10, or 90. Chlorine is not only unrespirable, but very injurious when breathed, even if largely diluted: a taper burns in it with a red smoky flame, and is soon extinguished. Some of the metals, when finely divided, spontaneously take fire in chlorine, such as brass leaf, or powdered

CHLORIODINE

antimony: A remarkable property of chlorine is its power of destroying almost all vegetable and animal colours; hence the important application of this gas and of some of its combinations to the *art of bleaching*. It also destroys the putrid odour of decomposing vegetable and animal substances, and infectious effluvia of all kinds, whence its use in fumigation, and in preventing the spread of infectious and contagious matter, and purifying noxious atmospheres.

The great natural source of chlorine is *common salt*, which contains it in the proportion of about 60 per cent. It is procured by decomposing common salt by the joint agency of sulphuric acid and peroxide of manganese. The best proportions are 3 parts of salt and 1 of oxide of manganese; these are well mixed, and put into a retort with 2 parts of sulphuric acid previously diluted with 2 of water. Chlorine is evolved, and its extrication is quickened by the application of a gentle heat. Chlorine may also be obtained from a mixture of muriatic (hydrochloric) acid with half its weight of black oxide of manganese. The gas may be collected over water, and should be preserved in bottles with glass stoppers; if left in contact with water, it is soon absorbed. [MURIATIC ACID.]

Chloriodine or Chloriodic Acid. A compound of chlorine and iodine.

Chlorite. A soft mineral of a green colour, often found in cavities and veins in trap rocks. It is a constituent of most of the copper lodes of Devon and Cornwall, and is very common in all the quartz veins in the west of Cork. It is a hydrated silicate of alumina and magnesia, and is known to Cornish miners by the name of *peach*.

Chlorite Schist. A green slaty rock with foliated plates of chlorite and minute grains of quartz, or sometimes with felspar and mica. It passes into gneiss and clay-slate. Chlorite schist is one of a group of rocks having many properties in common. *Talcose Schist* differs from it only by the replacement of talc for mica; and many of the magnesian minerals, as asbestos, diallage, &c. are found with it. Garnets are frequently associated with these schists, and form what is sometimes called a *garnet schist*. All pass occasionally into Mica Schist [which see].

Chlorite Slate. The name applied to Chlorite (and Ripidolite) when occurring in mountain masses.

Chloritoid. A hydrated silicate of alumina and protoxide of iron, occurring in dark grey or greenish-grey folia, at Kossilbrod in the Ural, Bregratten in the Tyrol, Gumuch-Dagh in Asia Minor, and in the mica-schist of Leeds in Canada.

Chlorocarbonic Acid. A compound formed by exposing a mixture of chlorine and carbonic oxide to the action of light.

Chlorochloric Acid. A mixture of chlorous and chloric acids. Mixed with chlorine it forms *Euchlorine*, an explosive gas evolved when a chlorate is heated with hydrochloric acid.

CHLOROPHANE

Chlorochromic Acid. Chromic acid in which an equivalent of oxygen is replaced by one of chlorine. It is prepared from common salt, chromate of potash and strong sulphuric acid, and is a volatile red liquid emitting dense suffocating fumes when exposed to the air. Its combination with ammonia is attended by inflammation.

Chlorocyanic Acid. A compound of chlorine and cyanogen.

Chlorodyne. An anodyne remedy, sold under this name, is said to consist of a solution of morphia, extract of Indian hemp, oil of peppermint, &c. in a mixture of chloroform and ether.

Chloroform (Gr. *χλωρός*, *pale*, and *lat. formica*, *an ant*). A compound represented by the formula C_3HCl_3 , and obtained by distilling a mixture of chloride of lime with diluted alcohol. It is a heavy liquid, its sp. gr. being 1.48; it boils at 140° . Its name has reference to the constitution of *formic acid*, which is represented by $C_2H_2O_3$, and is therefore the teroxide of a hydrocarbon $= C_3H$, to which the term *formyle* has been applied; so that, in reference to this view of its composition, chloroform has also been denominated *terchloride of formyle*. When the diluted vapour of pure chloroform is respired, it soon induces insensibility, in the same way as ether vapour; and hence has been similarly used, in the performance of surgical operations and in childbirth. Much prudence and caution are requisite in its administration; but when pure, and duly diluted with atmospheric air, and in proper cases, it is a safe and very efficient anæsthetic.

Chlorometer. An instrument for the purpose of testing the decolouring or bleaching powers of *chloride of lime*, by which the relative values of different samples of that important bleaching and disinfecting compound may be ascertained. [CHLORIMETRY.]

Chloronitric Gas. Peroxide of nitrogen in which two equivalents of oxygen are replaced by two of chlorine. Yellowish red fumes are evolved when nitrohydrochloric acid is gently heated.

Chloronitrous Gas. Nitrous acid in which an equivalent of oxygen is replaced by one of chlorine. Evolved when nitrohydrochloric acid is boiled.

Chloropal. An amorphous mineral, of a yellowish-green colour, found associated with the Opal of Hungary. It is a hydrated silicate of iron.

Chlorophætte (Gr. *χλωρός*, and *φάει*, *dusky*). A hydrated silicate of protoxide of iron found in the amygdaloid of Scur More in Rum. The name has reference to the change of colour from green to dark-brown or black, which takes place on exposure in the course of a few hours.

Chlorophænerite. A hydrated silicate of protoxide of iron of a blackish-green colour, which is found in cavities of amygdaloidal porphyry at Weissig in Saxony.

Chlorophane (Gr. *χλωρός*, *green*, and *φάει*, *to seem*). A name given to those kinds

CHLOROPHYLL

of Fluor Spar which, when heated, shine with a beautiful emerald-green phosphorescent light.

Chlorophyll (Gr. *χλωρός*, and *φύλλον*, a leaf). The green colouring matter of the leaves of plants.

Chlorophyllite. Probably an altered or hydrated variety of Iolite. It occurs at Hadam in Connecticut in large prisms, or in foliated masses, of a greyish or brownish-green colour—usually associated with Iolite in granite. The name has reference to the colour and structure of the mineral.

Chloropierin. A pungent colourless oil derived from picric acid by the action of chloride of lime.

Chlorosis (Gr.) or **Etiolation**. In Botany, is a species of constitutional debility the affected plant is pale, and destitute of a healthy green: the stems are weak, long, and slender; no flowers are produced; and the plant is readily killed. This malady is produced or aggravated by bad drainage, or by cold ungenial weather, but is probably dependent mainly on the composition of the soil. The application of a very weak solution of sulphate of iron to the roots has been recommended as a remedy; but it should be accompanied by judicious treatment in other respects. It is artificially produced in celery, endive, sea-kale, and some other esculent vegetables, to destroy their bitter flavour and fit them for the table.

Chlorosis. In Medicine, a disease giving a peculiar sallowness to the countenance, hence called the *green sickness*. It chiefly affects young females; its symptoms are extremely various, but generally referable to imperfect or suppressed menstrual evacuation. Tonics, chalybeates, aloetics, sea and cold bathing, and slight electric shocks passed through the pelvis, together with due amusement and exercise, are among the principal remedial agents.

Chlorospinel. A grass-green Spinell from Slatoust in the Ural, in which some of the alumina is replaced by oxide of iron.

Chlorous Acid. An explosive yellowish green gas (= ClO₃), evolved when a chlorate, arsenious acid, and nitric acid are heated together.

Chlorous Pole. The voltaic pole or electrode at which chlorine is evolved in cases of the electrolysis of chlorine compounds. It is synonymous with *positive pole*. [ANODE.]

Chlorozalic Acid. A compound obtained by exposing acetic acid and chlorine to bright sunshine. Its elements are in such proportion, that it may be regarded as a compound of 1 equivalent of hydrochloric acid and 1 of oxalic acid.

Chloroxylon (Gr. *χλωρός*, and *ξύλον*, wood). A genus of *Cedrelacea*, known by its fruit having only three cells and splitting into three parts, instead of five. *C. Swirensia*, the satin-wood of India, is a tree of sixty feet high. Extensive imports of the timber are made, the principal uses to which it is applied being for making the backs of brushes, and for turnery

CHOLEIC ACID

ware, the finest pieces being cut into veneers for cabinetmakers.

Chlorurets. Compounds of chlorine. [CHLORIDES.]

Chœanites (Gr. *χœνα*, a funnel). A genus of extinct Zoophytes, so called on account of their fossil skeleton or polypary presenting in general a funnel-shaped figure, though sometimes they are globular or subcylindrical. This genus holds an intermediate place between *Alcyonium* and *Ventriculites*: it is distinguished from the former by having a central cavity at the upper part, and from the latter by not having an outer reticulate surface. One species, the *Chœanites Königi*, is found in abundance in the loose flints beneath the turf near the racecourse at Lewes in Sussex, and appears to have been common in the upper beds of the Chalk.

Checks. On Shipboard, are large wedges of wood driven under the sides of boats, casks, or any curved object, for the purpose of preventing motion when the vessel rolls. *Rudder-checks* are wedges kept in readiness to stop the motion of the rudder, should any accident render it unmanageable.

Chocolate. A term said to be compounded of two Indian words, *choco*, sound, and *alta*, water, from the noise made in its preparation. Chocolate is made by triturating the roasted cacao-nut into a paste in a heated mortar, sugar and some aromatics being occasionally added; the oily matter of the nut gives it whilst hot a due consistence, so that it is cast in tin moulds, in which it concretes, on cooling, into cakes.

Chœir (Fr. *chœur*, Lat. *chorus*, Gr. *χορός*). In Architecture, that part of the church in which the choristers sing the divine service. In former times it was separated from the nave by an ambo or rood screen, in which the epistles and gospels were read, as may still be seen in many of the churches on the Continent, and in the best models in our own country. It was separated from the nave in the time of Constantine. In nunneries, the choir is a large apartment, separated by a grating from the body of the church, wherein the nuns chant the service.

This term is also used in Music, to signify a band of singers in parts, or even the chorus itself.

Choke-damp. A term applied by well-diggers and miners to carbonic acid gas.

Cholagogues (Gr. *χολαγωγός*, carrying off bile). Purgatives producing bilious motions.

Choledochus (Gr. *χοληδόχος*, containing bile). One of the ducts of the liver is called the *ductus communis choledochus*.

Choleic and Cholic Acid. Choleic acid is a fatty acid, which, in combination with soda, constitutes a principal ingredient in *bile*. By the protracted action of caustic potash it evolves ammonia, and is converted into *Cholic acid*. The elements of choleic acid are carbon, hydrogen, oxygen, nitrogen, and sulphur, the following being its formula: C₄₄ H₄₀ O₉ N S.

CHOLEPYRRHIN

Cholepyrrhin. The brown colouring matter of human bile.

Cholera (Gr.) A disease accompanied by vomiting and purging, with great pain and debility, and apparently arising from excess or acrimony of bile: it is most common at the close of summer and beginning of autumn, and seems to be produced by cold, suppressed perspiration, indigestible fruits, &c. It generally commences with a sense of pain about the bowels, fever, thirst, an irregular pulse, and severe vomiting and purging of bilious matter: in favourable cases these symptoms subside in a few days with the aid of opiates, mucilaginous diluents, and mild aperients followed by tonics; but in severe cases great exhaustion ensues, attended by depression, anxiety, hurried respiration, cold sweats, hiccup, low and fluttering pulse, and the patients rapidly sink. In such cases warm fomentations sometimes relieve the pain, and effervescent saline draughts check the sickness and enable the stomach to bear large doses of opium.

CHOLERA, ASIATIC. The term *Asiatic* or *Spasmodic Cholera* has been applied to a most appalling form of pestilential disease, which seems to have been but indistinctly known prior to the year 1817. It made its appearance in August that year at Jessore, after having previously raged to a formidable extent in the south of Bengal, and thence it spread over a great part of Asia, carrying off millions of human beings. In 1823 it broke out at Astracan, but did not at that time extend farther into Russia; in 1828, however, it appeared at Orenburg, and during the autumn of that year and the spring of 1829 it spread over a considerable part of the Russian dominions. It raged at Moscow in September 1830; and having been apparently carried by the Russian army into Poland, it propagated itself through different parts of Europe, and reached this country. The symptoms of this, as of other disorders, vary considerably at different times and in different individuals; but as our object here is briefly to describe the characteristic features of the disease in their unalloyed form, we shall omit all unnecessary details, and place before our readers a short account of its effects in its worst and by no means uncommon form.

The first circumstance that strikes us in regard to the attacks of this disease is their suddenness. A person in apparent health feels slightly giddy, chilly, or sick, and in the course of two or three hours sinks into a state of extraordinary and alarming debility; the countenance assumes a deadly paleness, and the skin feels and looks like that of a corpse; the pulse falls, flutters, and is almost imperceptible; a livid circle surrounds the sunken eyes; the tongue is slightly furred, and the breath cold. Under this excessive and extraordinary prostration, the patients sometimes die in the course of a very few hours; otherwise it is succeeded by vomiting and purging, the voided matters resembling turbid whey,

CHOLERA

being in fact a serous fluid with floating shreds or flocculi of coagulated albumen; and now cramp assails the extremities, and afterwards the abdomen, producing spasms of varying but sometimes of extreme violence; great pain and heat about the region of the stomach, and intolerable weight and anguish round the heart are complained of, with much thirst and anxiety; the voice falters, and the unfortunate sufferer asks frequently, in plaintive and broken whispers, for cold water; the secretions of urine, bile, and saliva appear, in this state of things, as if entirely suspended; the evacuations have a singular fætor, and the breath and perspiration have that peculiar odour which announces the rapid approach of death. Towards the close of this horrid scene, the respiration becomes very slow, the tendons of the extremities quiver, the sufferer is unable to swallow, insensibility succeeds, and after one or two long and convulsive sobs he dies. The mind, even at last, is scarcely ever much disturbed; but towards the close the patient sinks into a state of apathy, and appears desirous of being left to his fate. Attacks of this kind generally prove fatal in from four to eight hours.

The appearances observed on dissection of those who died within eight or ten hours were: a relaxed and pale state of the stomach and intestines; absence of bile and of feces in the intestines; an empty and contracted bladder; congestion in the venous circulation of the large vessels; the gall-bladder full of bile, but not passing into the intestine. In more protracted cases other appearances occasionally occurred, more especially serous effusion upon and in the brain, with congestion of the vessels, and other usual appearances of febrile disease. In all cases the blood presents a more or less morbid appearance, and is often of a very dark colour and increased consistence, so as to have been compared to tar.

The pathology of cholera is as yet most imperfectly understood; nor has it been satisfactorily ascertained whether it is or is not contagious; the general opinion, however, is in favour of its contagious nature, and there cannot be the least doubt of the propriety of enforcing the most rigid precautionary measures founded upon such an opinion.

Details respecting the *medical treatment* of cholera would be out of place in this work; and the plans to be pursued vary so much with circumstances, as to render it impossible to condense into small limits a general view of this important subject.

If from this extreme case we turn to what may be termed milder forms of the disease, the same general train of symptoms are observed; but they are less rapid in their succession, and there is more time and opportunity to resort to the resources of art. The attack begins with sickness or purging, succeeded by uneasiness and heat about the pit of the stomach; the matters which are thrown off from the stomach and bowels gradually assume the appearance of rice-water; the countenance shrinks; the con-

CHOLERA

striction of the thorax and cramps and spasms follow; and in the course of twenty-four to thirty-six hours the patient dies, in many instances delirious or comatose.

Those who survive seventy-two hours generally recover, as far as the primary symptoms are concerned; the spasms and difficulty of breathing give way, the natural warmth of the body is restored, and the pulse returns to something like its natural standard. The most favourable symptoms are sleep, perspiration, return of the secretion of urine and of bile, accompanied by proportionate improvement in the pulse and aspect of the features; but, even under these apparently and really favourable symptoms, fever of a low or continued character may ensue—it indeed sometimes immediately follows the blue stage or collapse; and, if not relieved by a critical perspiration on the second or third day, the pulse quickens, the face is flushed, there is drowsiness and suffusion of the eyes, stupor, a foul mouth, and other symptoms of mixed or typhus fever, which terminate fatally from the fourth to the eighth day, or even later, in those very individuals who had been saved in the first or cold stage.

Emetics were among the earliest measures which were put in practice; they should be such as act certainly and rapidly, if used, and be joined with stimulants, such as essential oils and capsicum. *Blood-letting* has been adopted by many practitioners in the early stages of the disease. Its favourable effect is to cause the pulse to rise; if it produce faintness, it must be immediately put a stop to, and should be followed by the application of warm air, and other dry warmth. Large doses of calomel, with or without opium, are resorted to to remove local congestion, and especially to stimulate the liver; and these means are assisted, and the general powers of the system kept up, by ether, ammonia, brandy, and volatile oils, in such quantities and forms as the particular circumstances of the respective cases may point out. If the irritability of stomach should continue, flannels soaked in very hot water, and then sprinkled with oil of turpentine, should be applied to the region of the stomach and abdomen.

The great object of all those remedies applicable to the first stage of the disease is to enable the system to rally from its depressing effects, to bring about reaction, and to stimulate the nervous and vascular systems; but then the utmost circumspection is required in reference to the injurious effects which this plan will induce, if carried too far. On reaction, the symptoms are usually those of typhoid or continued fever, and are to be treated accordingly, great attention being always paid to the state of the biliary and urinary secretions, and to the evacuations from the bowels.

Besides the treatment founded upon the above outline, other and very dissimilar plans have been adopted, founded upon the change which the blood appears to suffer in this disease. It has been by some presumed that in all cases

of cholera the saline matters of the blood, along with a large quantity of its water, are thrown off by the intestines, constituting the characteristic serous discharge above adverted to; and that the residuary blood becomes thick and black, in consequence of the deficiency of its salts. Dr. Stevens therefore proposed the administration of large doses of common salt, occasionally mixed with nitre and chlorate of potash; and from this plan the best effects have, according to some, resulted, while in the hands of others it has entirely failed. The truth is, that in the worst attacks of the disease the approach of death is so quick that there is scarcely time for anything to take effect; and where it is less rapid, the symptoms must guide the treatment: amongst these it must be confessed that there are seldom any which would justify the prudent practitioner in drenching the bowels with salt and water.

But the bolder advocates of what has been termed the *saline treatment* of cholera have gone a step further, and have dared to inject saline solutions into the veins: how far such extraordinary means are justifiable, will appear from the following statement (Pereira, *Elements of Materia Medica*, part i. 313): 'This plan was, I believe, first practised by Dr. Latta. (*Med. Gaz.* x. 257.) The quantity of saline solution which has been in some cases injected is enormous, and almost incredible. In one case 120 ounces were injected at once and repeated to the amount of 330 ounces in twelve hours. In another, 376 ounces were thrown into the veins, between Sunday at 11 a.m. and Tuesday at 4 p.m.; that is, in the course of fifty-three hours, upwards of 31 lbs. The solution used consisted of two drachms of muriate and two scruples of carbonate of soda to 60 ounces of water. It was at the temperature of 108° or 110° Fahr. In another series of cases 40 lbs. were injected in twenty hours; 132 ounces in the first two hours; 8 lbs. in half an hour! The *immediate* effects of these injections, in a large majority of cases, were most astonishing—restoration of pulse, improvement in the respiration, voice, and general appearance, return of consciousness, and a feeling of comfort. In many instances, however, these effects were only temporary, and were followed by collapse and death.'

In his recently published *Notes on Cholera, its Nature and its Treatment*, Dr. George Johnson, Professor of Physic in the Medical School of King's College, maintains that the thickening of the blood is a consequence and not a cause of choleraic collapse, which is the result of defective oxygenation of the blood and of the various tissues of the body. Hence follows, also, the diminished exhalation of carbonic acid, and the almost complete suppression of bile and urine, the chief constituents of these being all results of oxidation. The remedies on which Dr. Johnson places most reliance are venesection, to counteract the collapse, and the administration of mild evacuant drugs, to aid in expelling the poison which nature

CHOLESTERIN

seeks to drive out by the diarrhoea which generally accompanies the attacks of this disease.

Among other works on the subject, the reader may consult the Reports published by order of government, under the superintendence of the Medical Board; *History of the Epidemic Cholera*, by B. Hawkins, M.D., &c.; Mr. Bell's *Letter to Sir H. Hallford*; the Report of Drs. Russell and Barry; Dr. James Copland *On Pestilential Cholera*; Chapman, *Functional Diseases of the Stomach*.

Cholesterin. The peculiar fatty matter which forms the basis of most gallstones:

Chondrine (Gr. *χόνδρος*, cartilage). That form of gelatine which is obtained from cartilage, and which differs from ordinary gelatine in being precipitable by acetic and the mineral acids, and by sulphate of alumina and potash, persulphate of iron, and acetate of lead.

Chondrodite (Gr. *χόνδρος*, a grain; because of its granular structure). A native silicate of magnesia with part of the oxygen replaced by fluorine and part of the magnesia by protoxide of iron. It occurs in indistinct crystalline masses or embedded grains of a wax-yellow or brown colour, having an occasional but not very decided appearance of regular crystalline form. It is found at Loch Ness in Scotland in granular carbonate of lime, and at Gweedore, county Donegal, in Ireland, in crystalline Dolomite. The largest and most crystalline masses are met with near Sparta in New Jersey, and near Edenville in New York. Other localities are Finland, Sweden, Saxony and the Ural. [HUMITE.]

Chondrology (Gr. *χόνδρος*, a cartilage, and *λογία*, a discourse). The history of cartilages.

Chondropterygians (Gr. *χόνδρος*, and *πτερυγία*, a fin; *gristly-finned*). The name of Cuvier's last order of Fishes, characterised by the gristly nature of all the spines which support the fins. The whole internal skeleton in this order is cartilaginous.

Chemicerite or **Chemitrite** (a word made up from Gr. *χώρα*, *χώρα*, a melting-pit, and *κεράς*, test: *d*). A hydrosilicate of alumina, magnesia, and lime, which is found in white irregular masses, with shades of yellow and grey, in the Serpentine of Ellas, associated with Pyrosclerite, of which it is probably only a variety.

The name indicates its difference from some allied minerals with respect to fusibility.

Choric Monument. In Grecian Architecture, this word is applied to a monument raised in honour of the Choragus who, at Athens, was appointed by his tribe to provide a chorus for a play acted at the Dionysia. [LITURGIC.] Of the several choragi, he who did his duty best received a tripod, which the victor was bound to exhibit publicly, and for this purpose a building, or column, was erected. The remains of two very fine monuments of this sort, viz. those of Lycierates and of Thrasyllus, are still to be seen at Athens; they are represented in Stuart's *Athens*.

CHORDÆ VOCALIS

Chord (Gr. *χορδή*, a gut-string). In Geometry, is the straight line which joins the two extremities of the arc of a curve; so called from the resemblance which the arc and chord together have to a bow and its string, the chord representing the string. The chord of a circular arc is obtained by multiplying the radius by twice the sine of half the angle which the arc subtends at the centre. Tables of chords are given in some of the older works on trigonometry; but they have been superseded by the tables of sines, which are much more convenient for trigonometrical calculations.

Since two circles cannot cut one another in more than two points, they can only have one chord in common. The principle of continuity, however, to the recognition of which the progress of modern geometry is so much indebted, sanctions and suggests a different mode of expression. Circles are curves of the second order, and, as such, are said to intersect in four points; two of these points, however, are always imaginary and situated on the line at infinity. [CIRCLE.] They are the so-called circular points at infinity. Of the six common chords, then, which two quadrics (e.g. ellipses) in general possess, four are always imaginary in the case of two circles, and two always real. Of these two, however, one is always infinitely distant; the other, which may or may not cut the two circles in real points, is often called their *radical axis*, and possesses many remarkable properties.

Chord. In Music, a combination of two or more sounds heard together, so as to form harmony. [MUSIC.]

Chord of Curvature. The segment intercepted upon the radius vector to any point of a plane curve, referred to polar coordinates, by the circle of curvature at that point. If r be the radius vector and p the perpendicular from the pole on the tangent, $\frac{p}{r}$ is easily seen to be the sine of the angle subtended at the circumference of the circle of curvature, by the chord of curvature; so that the latter will be expressed by $2p \frac{p}{r}$; where

p is the radius of curvature. In the logarithmic spiral, for instance, where the centre of curvature is always in the perpendicular to the radius vector through the pole, the chord of curvature is always double the radius vector.

Chorda Dorsalis (Lat.). [NOTOCHORD.]

Chorda Tympani (Lat.). A branch of the facial nerve or portio dura, which crosses the tympanum, and supplies the lingualis and some other muscular fibres of the tongue.

Chordæ Vocales (Lat.). In Anatomy, are the ligaments which extend from the thyroid to the cricoid cartilages, and bound the glottis. They contain much elastic tissue, and can be made to vibrate under various degrees of tension by the action of the muscles upon the cartilaginous parts of the larynx to which they are attached; they are the proper organs of voice.

CHOREA

Chorea (Gr. *χορεία*, dancing). The disease commonly called *St. Vitus's dance*. It shows itself by convulsive motions of the limbs, face, head, and trunk, varying extremely in extent and violence; the speech is often more or less affected, and frequently the mental energies become grievously impaired. It is most common in early life, as from the age of ten or twelve to puberty; and makes its approach gradually in persons chiefly of debilitated constitutions: the appetite is generally ravenous at first, and the bowels costive; various convulsive motions then ensue, and only cease during sleep, which, however, is seldom sound. This is one of those diseases which require especial attention in its early stages, and which even in its slightest forms, when once habitual, is very difficult to manage. The leading treatment consists in the judicious administration of aperients and brisk purges, so as to clear the stomach and bowels thoroughly of all irritating matters: the constitution may at the same time be strengthened by tonics and chalybeates, with occasional stimulants; and some of the more urgent spasmodic symptoms may be sometimes cautiously encountered by opium, camphor, henbane, and ether. Cold bathing also has its advantages when circum-spectly resorted to; and the mind must be diverted by change of air and scene. The diet should be very regular, nutritive, and never in excess. In this complaint much will depend upon the exertions of the patient himself, who, though relieved of the more urgent symptoms, will often retain relics of his disorder through a long life.

Chorepiscopi (Gr. *χορηγισκός*). Country bishops; persons appointed by the bishops in the early periods of Christianity to superintend the rural districts which appertained to their dioceses, but which were at an inconvenient distance from the city in which they abode themselves. The class of chorepiscopi is represented as holding a middle rank between the bishops and the presbyters.

Chorion (Gr.). The external membrane which envelops the *fetus in utero*, between which and the amnion there is a gelatinous fluid. Its interior surface is smooth, but externally it is shaggy and vascular.

Choreograph (Gr. *χορογράφος*). The name given by the late Professor Wallace, of Edinburgh, to an instrument contrived by him for the mechanical construction of this geodetical problem; viz. 'To determine the position of a station, having given the angles made by lines drawn from it to three other stations in the same plane, whose positions are known.' The problem, which is important from its frequent application in maritime surveying, was reduced by Professor Wallace to another very

one; viz. 'To construct two similar triangles on two given straight lines, having given its angles.' (Wallace's *Geometrical Theorems and Analytical Formulae*, &c. Edinburgh, 1839.)

Choreography (Gr. *χορογραφία*). The description of a district, in contradistinction to

CHRESTOMATHY

geography (the description of the earth or of countries) and topography (the description of particular spots).

Choroid Membrane of the Eye. The second tunic of the eye lying under the sclerotic, with which it has a vascular connection: it commences at the optic nerve, and passes forward with the sclerotic to the beginning of the transparent cornea, where it firmly adheres to the sclerotic by a cellular membrane, forming a white fringe called the *ciliary circle*; it then recedes from the sclerotic and cornea, forming a round coloured disc called the *iris*, and its posterior surface is termed *uvea*. The choroid membrane is very vascular, and its external stellated vessels are called *vasa verticosa*. Its internal surface is covered by a *black pigment*.

Choroid Plexus. A plexus of blood-vessels situated in the lateral ventricles of the brain.

Chorus (Lat.; Gr. *χορός*). In the Greek theatre, a band of singers and dancers who sang the odes introduced into the drama. The chorus played an important part in the Greek tragedies and early comedies. The duty of furnishing these Choruses was one of the three Liturgies or public burdens imposed on the richest private citizens of Athens. [LITURGY.]

The term is used in modern Music for a vocal composition in which each part is sung by many voices together. The word is also applied to the body of the singers themselves.

Chose (Fr. *thing*, from Lat. *causa*) in Action. In Law, is defined to be personal property whereof the owner hath not the possession (in the technical sense), but only a right of action to recover it; as, a debt on bond or covenant.

Chouans. In French History, the royalist insurgents on the right bank of the Loire during the Revolution, when the Vendéans rose on the left, were thus popularly named; according to some, from the cry of the screech-owl (*chou-luant*), an imitation of which was a signal during their nightly meetings. They were for the most part brigands, and their object rapine rather than civil war. After the Revolution of 1830, they made a transient reappearance in the neighbourhood of Nantes and Le Mans.

Chrestomathies (Gr. *χρησματομαθία*). The science of wealth; a name given by Continental writers to the science of political economy, or rather to what in their view constitutes a portion of the science. They consider *political economy* as a term more properly applicable to the whole range of subjects which comprise the material welfare of states and citizens, and *chrestomathies* (by which they mean nearly the same science which Mculloch and most other English writers describe as political economy) as merely a branch of it. See especially M. de Sismondi, *Études sur l'Économie Politique*. [CERYSOLOXY.]

Chrestomathy (Gr. *χρηστομαθία*). According to the etymology, that which it is useful to learn. The Greeks frequently formed commonplace books by collecting the various passages to which, in the course of reading, they had affixed the mark χ (*χρηστός*). Hence books of

CHRISM

extracts chosen with a view to utility have received this name.

Chrism (Gr. *χρίσμα*, from *χρίω*, *I anoint*). The oil which is used both in the Greek and the Romish churches in the administration of baptism, confirmation, ordination, and extreme unction.

Chrysomelinae. A mineral resin found in the coal formation at Wettin, near Halle.

Christ (Gr. *χριστός*, *anointed*, answering to 'Messiah' in Heb.). The name given as a title of eminence to the Lord Jesus, whom, in the words of St. Peter (Acts x. 38), 'God anointed, as king, priest, and prophet, 'with the Holy Ghost and with power.'

Christendom. A word sometimes employed in such a sense as to comprehend all nations in which Christianity prevails; more commonly all realms governed under Christian sovereigns and institutions. Thus European Turkey, although three-fourths of its inhabitants are Christians, is not in ordinary language included within the term *Christendom*. The history of the fortunes of Christianity, in respect of its geographical extension, presents remarkable periods of advance and decline. After the conversion of Constantine, and the gradual decay of Paganism, Christianity continued to spread, but chiefly in the direction of east and south, for more than three centuries, the barbarian conquerors of the Roman provinces soon adopting it. About the middle of the seventh century, Christendom comprehended Europe south and west of the Rhine and Danube; Africa north of the Great Desert; Abyssinia; parts of Nubia; Asia to the Euphrates; Armenia, and part of Arabia; and that small colony in Southern India which subsists to this day. The Saracen power rose, by conquest, from this extensive empire. In little more than a century Christendom was deprived of nearly all its Asiatic provinces, of which the faithful inhabitants were reduced to a tributary condition; of the whole of Northern Africa, in which they were exterminated or converted; and of Spain. Sicily, the latest conquest of the Saracens, was occupied by them about 830. But just at the same epoch, or that of lowest decline, Charlemagne began to extend the limits of Christendom to the north; and the second period of advance extends through the ninth, tenth, and eleventh centuries, in which 'the reign of the gospel and the church was extended over the north: Bulgaria, Hungary, Bohemia, Saxony, Denmark, Norway, Sweden, and Russia.' (Gibbon, chap. lv.) From that time to the sixteenth century, Christianity gradually reconquered Spain on the one hand; while, on the other, the newly arisen power of the Turks wrested from it the remainder of its Asiatic territories and the European provinces of the Greek empire. Since that period no important changes have taken place in the relative extent of Christendom and Islamism; but the vast continent of America, as far as it has been colonised, has been added to the former, and

CHRISTIANITY

the rapid increase of its communities in numbers and civilisation has greatly enhanced their comparative importance. The number of Christians inhabiting Europe and America, and scattered in the other parts of the globe, may perhaps be estimated conjecturally as follows:—

Roman Catholic church	180,000,000
Reformed churches	80,000,000
Greek and other Oriental churches	70,000,000
	<hr/> 330,000,000

If we estimate the number of Christians at 300 millions, one half perhaps of this amount may be assigned to the Roman Catholic church, and the other half nearly equally divided between the various Reformed churches on the one hand, and the Greek and other Oriental communities on the other.

Christianite. The name given by Monticelli to the Anorthite of Vesuvius, in compliment to Prince Christian of Denmark. The same name has also been given by Des Cloizeaux to the Harmotome from Stempel, near Marburg.

Christianity. The religion of Jesus Christ. From the period when the disciples 'were called Christians first in Antioch' (Acts xi. 26) down to the present day, the main doctrines of the gospel, and the great moral principles which it reveals and confirms, have been preserved without interruption in the church. But notwithstanding this substantial unity, it cannot be denied that the character of the religion has been very materially coloured throughout all its history by the circumstances and genius of different nations and ages. The first marked forms of opinion which acquired consistency among the general body of Christians tended in two very different directions. The *Judaising* Christians clung to the ordinances of the elder religion; but although under the names of Nazareans &c. they existed as late as the fourth century, they ceased after the first to exercise any very extensive influence on the church. The *speculative* Christians placed figurative interpretations both on the external facts and mysteries of the religion, or sought to connect it with the philosophical and theological systems of the ancient world. Apollon of Alexandria was the first teacher, it is commonly said, who introduced this speculative tendency into Christianity; and St. Paul, while he does not condemn Apollon, dwells on the evils produced by those who from his teaching deduced as it were a separate body of doctrines (1 Cor. ii.). In this way arose: 1. The early heretics, the Nicolaitans and followers of Cerinthus, and the Gnostics, professors of the 'knowledge falsely so called' (*ψευδάνωμος γνῶσις*) of St. Paul.

At a later period, the Manichæans, who imported into Christianity the notion of the rival principles of good and evil, which continued for many ages to possess adherents. 3. Within the church itself, the *Alexandrian school of theology*, which has exercised a more permanent influence, 'his school, in the second and third centuries,

CHRISTIANITY

became partially tinged with the sentiments of Platonis philosophy; and was characterised by the acute and refining spirit of the East. Like the Gnostics, its chief doctors encouraged the notion of a mystical or second meaning in the revelations of the faith, of which the key was in the possession of the learned only (Clemens, Origen, &c.). In the meantime, the main body of believers, comparatively unaffected by the influence of science and speculation, was gradually acquiring new views of a different and more positive character. During the first three centuries after the apostolical times, the opinions respecting the authority of the priesthood, the attachment to forms and ordinances, the honour paid to individual purity of life (and especially to constancy under persecution), gradually and steadily increased and strengthened. In the West, and particularly in Africa, these tendencies became peculiarly strong. The Montanists, Donatists, and Novatians separated successively from the church, on the score of its defection from an imaginary standard of personal purity; and when Africa began to have a school of theology of her own (Tertullian, Cyprian, and others, to Augustine) this was the direction of its labours. In that theology all is dogmatical, nothing speculative. Everything is taken in its most literal and naked sense: God himself is not personal only, but invested almost with the attributes of a human agent. Both doctrines and ordinances are as definite as possible, and the utmost rigour of practice enjoined. The history of the African church affords a momentous commentary on these strainings after imaginary perfection. After two centuries of discord and decay from the time of Augustine, it was not only subdued but obliterated by the first assault of the Mohammedans. The early heretics had entertained theoretical notions respecting the inferiority of Christ to the Father; but the Arians, in the last half of the third century, were the first to preach it as the doctrine of the church, and to seek to confirm it by appeal to antiquity. The council of Nice (A.D. 325) condemned this opinion; but the Arians and other sects differing from the church by various shades of opinion on the same subject, continued to subsist until the sixth century, during which these controversies partly died away in the West, amidst the misery and barbarism of the age, and partly were extinguished by the authority of the church. It was thus that the governors of the church were first driven to protect its fundamental doctrines by reducing them to formal propositions embodied in creeds and the canons of councils (especially the six oecumenical or general, which were held from A.D. 381 to 680).

From this period, the history of Christianity embraces that of the separation of the Eastern and Western churches, A.D. 716 to the eleventh century; that of the Western reformation, which may be said to commence with the sectaries of the thirteenth century and end with the establishment of Protestantism in the sixteenth;

CHROMATICS

that of the struggle with Mohammedanism; of foreign missions; and of internal development—all too voluminous for anything more than reference.

Chromatic. In Music, a term referring to the alteration of a note by applying to it a sharp or a flat.

Chromatics (Gr. *χρωματῖς*). That part of Optics which treats of the colours of light and of natural bodies. This is a very important branch of physical science, and one which of late years has been prosecuted with great assiduity. Until Newton undertook his memorable experiments on the refraction of light, the cause of the different colours of bodies had never received any satisfactory explanation: such, indeed, was the difficulty which the ancients attached to this subject, that Plato considered it to be a usurpation of the rights of the Deity to attempt the investigation of this mystery of nature. The discovery of the difference of refrangibility in the coloured rays of the solar spectrum afforded a clue to the solution of the problem; and Newton demonstrated, by a series of decisive experiments, that colour depends not on any modification of light acquired by reflection or refraction, but is inherent in the light itself; the solar beam being composed of rays of all the colours contained in the spectrum, which are differently affected in passing through refracting media.

When a pencil of white light is decomposed by a prism [*SPECTRUM ANALYSIS*], the spectrum, or many-coloured band of light, thus produced is found on minute examination to contain a great number of dark lines, or fixed rays, parallel to one another and perpendicular to its length. These dark lines were first perceived by Dr. Wollaston; but it was Fraunhofer, a celebrated optician of Munich, who first accurately described the phenomenon, and pointed out the uses to which it could be applied. They are distributed very unequally through the spectrum, and the whole number amount to more than 1,000. Seven groups, which are more

easily perceived than the others, and which are distributed over the principal colours of the spectrum, have been distinguished by Fraunhofer by the letters B, C, D, E, F, G, H. Of these B is in the red space, near its outer end. J, which is a single line, and blacker than others contiguous to it, is near the limit of the red, next the orange. D is in the orange, and near the yellow; it is composed of two lines of equal darkness, very close to each other, and is easily distinguished. E is in the green, and consists of seven or eight rays. F is in the blue, G in the indigo, and H in the violet. Besides these, there are several other very remarkable groups, particularly one in the green, between E and F, which is composed of three strong lines. These lines always preserve

the same relative positions in respect of the boundaries of the coloured spaces; and though their distances vary with the nature of the prism by which they are produced, their number and order remain absolutely invariable so long as the light proceeds from the same source. This fixedness of position greatly facilitates the expression and communication of the results of chromatic researches. Professor Kirchhoff has recently made the important discovery that many of these dark lines in the solar spectrum are exactly coincident in position with the bright lines forming the spectra of the light emitted by ignited metals, and has artificially produced dark lines by absorbing the light evolved from a given ignited metal, by the heated vapour of the same metal. The irresistible conclusion is, that this absence of solar light which is spoken of as 'the dark lines of the spectrum,' is due to absorption of light emitted from the solid or liquid nucleus of the sun by the vapour of metals existing in the sun's atmosphere. In this way Kirchhoff's experiments indicate that iron, calcium, magnesium, sodium, nickel, and probably some other terrestrial metals, are constituents of the sun; while gold, silver, mercury, aluminium, cadmium, tin, lead, antimony, arsenic, strontium, and lithium are either absent or not present in sufficient quantity to produce an appreciable absorptive effect. It would therefore seem that the phenomenon of Fraunhofer's lines is due to the reversal, the negatives so to speak, of associated or superimposed spectra.

Colours of Natural Bodies.—Newton proved that the colour of any body is not the result of any quality inherent in that body, or in the particles by which it may be tinged, but is merely a property of the light in which they happen to be placed. The peculiar colours of bodies are only exhibited in a white light. If they are viewed by the simple and homogeneous light of any colour, they either appear black or of the colour of that light and no other. Hence we conclude that one body is red, and another violet, because the one is *disposed* to reflect the red or least refrangible rays, and the other the violet or most refrangible. The ordinary phenomena of colours may be explained on the principle of absorption. Every substance, how opaque soever it may be, transmits light, at least through a very small thickness; thus gold when reduced into thin leaf is translucent. From this fact it is assumed as a principle, that every particle of ponderable matter has the faculty of absorbing or extinguishing a determinate fraction of the luminous rays which fall on it or pass very near it, the remainder being reflected or transmitted. This fraction varies with the colour or species of colour of the incident luminous rays; and with the nature of the particle. For light of the same colour we may suppose it constant, whatever be the number of incident rays; so that the intensity of a homogeneous light, which has traversed a diaphanous plate composed of equidistant particles of the same

nature, will diminish in a geometrical, when the thickness of the plate increases in an arithmetical, progression. White light falling on the surface of an opaque body is not totally reflected at the surface, for, as has been just remarked, no substance is perfectly opaque: a portion of the incident light therefore penetrates the superficies of every body on which it falls, and is reflected by particles beneath the surface; and, in consequence of this interior reflection, is again emitted from the medium. But whilst the ray is thus penetrating and escaping from the body, the different colours of which it is composed suffer unequal absorptions; and on the totality of these absorptions depends the compound colour of the reflected ray, or the natural colour of the body. In this manner are explained the effects produced by coloured glasses, the blue colour of the sky, and the various tints of great masses of water.

For an explanation of the phenomena of the colours of thin laminæ, as soap bubbles, plates of mica, and of striated and grooved surfaces, see INTERFERENCE; LIGHT; REFRACTION.

Chromatic Scale. [SCALE.]

Chromatic Semitone. [SEMITONE.]

Chromatic Thermometer. When the edge of a rectangular plate of glass is applied to a piece of heated metal, or other substance having a temperature different from that of the glass, and exposed to a beam of polarised light, coloured fringes are developed; and as the particular tints depend on the difference between the temperature of the glass (which is supposed to be known) and that of the substance to which it is applied, the colour of the central fringe affords a means of inferring approximately the temperature of the substance. Hence the term *Chromatic Thermometer*.

Chrome Alum. The potassa-sulphate of chromium; a salt isomorphous with alum, in which alumina is replaced by oxide of chromium.

Chrome Chlorite. Hermann's name for a fibrous kind of Kammererite of a reddish-blue colour.

Chrome Mica. The name given by Breithaupt to an emerald-green Mica from Schwarzenstein in the Zillerthal.

Chrome Ochre (Gr. *χρῆμα*, colour). A substance found in earthy masses of a green or yellowish-green colour, in Unst, one of the Shetlands, filling small fissures in chromate of iron.

Chrome Orange. Formed on boiling yellow chromate of lead with lime. It is a dichromate of lead, and is a well-known pigment.

Chrome Stone. The name sometimes given to Chrome Ochre when it is so intimately mixed with the rock as only to be separated from it by chemical means. The ochre found between Conches and Creuzot in France, at Waldenberg in Silesia, and at Mortenberg in Sweden, is of this description.

Chrome Yellow. The yellow chromate of lead.

Chromic Iron or Chromite. A mineral composed chiefly of the oxides of chromium and

CHROMIUM

iron; a chromite of iron. It occurs crystallised in octahedrons, but commonly massive and disseminated in black grains. It is found in abundance in Unst and Fetlar in the Shetlands, as well as in some of the other smaller islands; also near Portsoy in Banffshire. It is also found at Gassin (Dépt. du Var) in France, in Saxony, Silesia, Styria, Hungary, Bohemia, Norway, Ceylon, and in large masses near Ekatherinenberg in the Eastern Ural, and at Tenos in Greece. It is the most abundant ore of chromium.

Chromium (Gr. *χρῶμα*, colour). A metal discovered by Vauquelin in 1797. It exists chiefly in two native compounds; the one formerly called *red lead* of Siberia, which is a *chromate of lead*; the other the compound of the oxides of chromium and iron. Chromium is a whitish, brittle, and very infusible metal (sp. gr. 5.6). When heated with nitre it is converted into *chromic acid*. Its equivalent number is 28. It forms two compounds with oxygen—a green oxide and a red peroxide; the latter being sour, and combining with salifiable bases, is called *chromic acid*. The oxide consists of 28 chromium + 12 oxygen; and chromic acid of 28 chromium + 24 oxygen. Chromic acid is of a red colour, and forms a variety of *coloured* compounds, some of which are much used in the arts; such as the *chromate* and *bichromate of potash*, largely manufactured for the use of calico printers, and the *chromates of lead*, employed as yellow and red dyes and paints. The oxide of chromium is green, and furnishes a valuable colour for porcelain and enamel. Chromic acid gives colour to the ruby, and the green of the emerald is due to oxide of chromium.

Chromo-lithography. [LITHOGRAPHY.]

Chromohydrocyanic Acid. A body analogous to ferrihydrocyanic acid or ferridcyanogen, but containing chromium in the place of hydrogen. It forms salts with positive elements.

Chromotartaric Acid. This body is conveniently described as bitartrate of chromium, but it really is an acid body and forms salts with bases.

Chromoxylography. In Printing, the art of producing coloured pictures by ordinary letter-presses from wood blocks, each colour having a block of its own and requiring a separate impression. Rainbow tints are formed by *braying out* various coloured inks so that the edges of each of the colours where they touch are as faint as possible.

Chromule (Gr. *χρῶμα*, colour). The green colouring matter of the leaves of plants; more commonly and properly termed *Chlorophyll*.

Chronic (Gr. *χρονικός*; from *χρόνος*, time). Diseases of long duration are termed *chronic*, in opposition to those of more rapid progress, which are called *acute*.

Chronicle. In Literature, an historical register of events in the order of time. Most of the historians of the middle ages were chroniclers who set down the events which happened

CHRONOLOGY

within the range of their information, according to the succession of years.

Chronicles. The name of two books in the canon of Scripture. They consist of an abridgment of sacred history from its commencement down to the return of the Jews from the Babylonish captivity, and are called by the Septuagint *παραινέματα* (lit. *things omitted*), because they contain many supplemental relations omitted in the other historical books. It has been supposed by Eichhorn and many other writers that the Chronicles were compiled by Ezra, though circumstances are not wanting to diminish the probability of this conjecture.

Chronogram (Gr. *χρόνος*, time, and *γράφω*, I describe). An inscription comprehending a date, which may be read by selecting all or some of the numeral letters, which are frequently written in these curious trifles in larger characters than the rest; as,

'ChristVs DVX ergo triVMphVs.'

(A medal of Gustavus Adolphus.) Sometimes united with an anagram; as one in honour of General Monk,

'GeorgIVs MonCe DVx de AumarLe;'

which may be read,

'Ego Regem reduxi, Ano. Sa. MDCLVV.'

Chronology (Gr. *χρονολογία*). The science which treats of the various divisions of time, and of the order and succession of events.

In order to ascertain and register the intervals of time between different events, two things must necessarily be assumed: *first*, an epoch or fixed point in time to which all events, whether preceding or succeeding, may be referred; and *secondly*, a measure or definite portion of time, by which the intervals between the fixed epoch and other events may be estimated. Of these the first is entirely arbitrary, and the second arbitrary to a certain extent; for though certain periods are marked out by the recurrence of natural phenomena, a choice of these phenomena must be made. It is on account of the arbitrary nature of these two elements, on which all chronological reckoning depends, that so much confusion and uncertainty exist respecting the dates of historical events.

The diversity of epochs which have been assumed as the origin of chronological reckoning, is a natural consequence of the manner in which science and civilisation have spread over the world. In the early ages the different communities or tribes into which mankind were divided began to date their years each from some event remarkable only in reference to their own individual history. Hence not only different nations, but almost every individual historian or compiler of annals, adopted epochs of their own. Events of local or temporary interest were also constantly occurring in every community which would appear of greater importance than those which were long past, and consequently be adopted as new historical dates. The foundation of a monarchy or a city, or the accession of a king, were events of this class, and accordingly are epochs of frequent occurrence in the ancient annals.

CHRONOLOGY

Religion also came in to increase the confusion caused by political changes. Soon after the introduction of Christianity, the various sects began to establish eras, commencing with events connected with the appearance of Christ; but no regard was given to uniformity. In like manner, the Mohammedans employ dates having reference to the origin of their faith. All these circumstances have conspired to render it a task of extreme difficulty for modern historians to ascertain the order of the political occurrences of ancient times.

But it is not merely the number of chronological epochs and the various origins of eras that have caused the perplexity; the measure by which long intervals were compared varied in different countries and in different ages; hence arises another source of confusion in arranging the order of time. In the Scripture history the lapse of time is frequently estimated by generations or reigns of kings. Some of the historians of early Greece reckoned by the succession of the priestesses of particular temples or cities; others by that of the ephori of Sparta; and others again by the archons of Athens. (Thucydides ii. 2.) Even when the length of the solar year began to be used as the measure of time, uniformity was not obtained. The length of the solar year is a fixed element in nature, and liable to no variation; but neither the commencement nor termination of the year is marked by any conspicuous sign. Its precise length can only be ascertained by a long-continued series of astronomical observations. Rude nations were therefore unacquainted with it; and even when it had become known with considerable accuracy, it was still necessary to form a civil year, and adapt it to the seasons, the solar year not being composed of an exact number of days. Most nations had recourse to intercalations [CALENDAR] for this purpose. The ancient Egyptians followed a purely solar year, which consisted of exactly 365 days. Its commencement, therefore, fell one day earlier with respect to the seasons every four years, and in the period of about 1,460 years would successively fall on every day in the year, and a whole year be gained in the reckoning. The civil year of the Jews, the Greeks, and many other nations, was regulated partly by the sun and partly by the moon, which rendered its adjustment still more complicated and difficult. (Sir G. Lewis, *Astronomy of the Ancients*, ch. i.) The Mohammedan year is purely lunar; and we can only pass from their calendar to the *Gregorian*, which is used in Christian countries, by first finding the number of days from the commencement of their era to any given event, and then turning them back into *Gregorian* years. [HINDU.] The Chinese, Hindus, and some other Asiatic nations, have epochs and methods of reckoning peculiar to themselves. [TABULATION OF CHRONOLOGY.]

For these reasons, and numerous others that might easily be adduced, it is very seldom that the precise interval between the events men-

CHRYSANILLO ACID

tioned in ancient history and modern dates can be determined with any degree of certainty, and great discrepancies exist among the computations of different chronologers. A remarkable instance of this occurs with regard to the computations made to determine the epoch of the creation of the world from the Scripture history. Desvignoles, in the preface to his *Chronology of Sacred History*, mentions that he had collected upwards of 200 different calculations, the shortest of which reckons only 3,483 years between the creation and commencement of the common era, and the longest 6,984; the difference being no less than thirty-five centuries. The most important works on chronology are—Usher's *Annales Veteris et Novi Testamenti*; Newton's *Chronology*; Blair's *Chronology and History of the World*; Playfair's *Chronology*; *Tables Chronologiques de l'Histoire Ancienne et Moderne*, by Thourret; Clinton's *Fasti Hellenici*; and above all others, *L'Art de Vérifier les Dates*.

Chronometer (Gr. *χρόνος*, *time*, and *μέτρον*, *measure*). A watch of peculiar construction, and great perfection of workmanship, used for determining geographical longitudes, or other purposes where time must be measured with extreme accuracy. The chronometer differs from the ordinary watch in the principle of its escapement, which is so constructed that the balance is entirely free from the wheels during the greater part of its vibration; and also in having the balance compensated for variations of temperature. Marine chronometers generally beat half-seconds, and are hung in gimbals, in boxes about six or eight inches square. The pocket chronometer does not differ in appearance from the ordinary watch, excepting that it is generally a little larger. Chronometers are of immense utility in navigation, and ships going on distant voyages are usually furnished with several, for the purpose of checking one another, and also to guard against the effects of accidental derangement in any single one. The accuracy with which chronometers have been found to perform is truly astonishing; the error in the mean daily rate in a two months' voyage sometimes not exceeding two or three seconds.

Chryodine. A dark-violet matter formed when sulphuric acid acts upon chrysammie acid.

Chrysalis (Gr. *χρυσάλλis*, from *χρυσός*, *gold*). The second state of a Metabolian or changeable insect, in which it becomes inactive, takes no food, and is enclosed in a transparent covering, which in many instances reflects a metallic lustre; whence the name.

Chrysamide. Bronze-coloured crystals obtained on boiling chrysammie acid with solution of ammonia.

Chrysamidic Acid. Olive-green crystals deposited from a boiling solution of chrysammie acid in dilute hydrochloric or sulphuric acid.

Chrysanillo Acid. A bluish red precipitate formed when an acid is added to a solution of indigo in potash.

CHRYSANISIO ACID

Chrysanisic Acid. Small golden scales resulting from the action of hot fuming nitric acid on nitranisic acid.

Chryselephantine (Gr. χρυσελφάντινος, from χρυσός, *gold*, and έλέφας, *ivory*). A name given by Greek sculptors to those statues which were overlaid with ivory and gold. The most celebrated of these was the colossal statue of Athéné, the work of Phidias in the age of Pericles. The gold of this statue was plundered by Lechares, and the statue itself was afterwards taken by order of Justinian to adorn the Hippodrome of Byzantium. We are therefore left to the description of Pausanias, and to the figures engraved on some medals, in order to determine the general character of works of this class. This uncertainty has given rise to some sharp controversy. An attempt to restore the great statue of Phidias has been made by M. Beulé, at the cost of the duc de Luynes, but the faithfulness of the restoration has been questioned by M. Alphonse de Calonne. (*Edinburgh Review*, July 1859, art. 'Acropolis of Athens,' p. 57.) [POLYCHROMY.]

Chrysobalanaceæ (Chrysobalanus, one of the genera). A natural order of shrubby or arborescent Exogææ, chiefly inhabiting the hotter parts of the world. They are very nearly related to *Rosacææ*, from which they differ in having a style proceeding from the very base of the ovary, and irregular stamens and petals. The species are of little importance. The fruit of *Chrysobalanus Icaco* is eaten in the West Indies under the name of the Cocoa Plum, and that of some others is used in other countries in a similar way.

Chrysoberyl (Gr. χρυσός, and βήρυλλος, *beryl*). An aluminate of glucina, composed of 80·2 per cent. of alumina and 19·8 of glucina. It occurs in small rounded masses about the size of a pea, but sometimes crystallised in eight-sided prisms with six-sided summits which are transparent or translucent, very hard, and of various tints of greenish-yellow, sometimes with a bluish opalescence internally. It is found in Ireland in the granite of the Mourne Mountains, and at Glenmalur, county Wicklow, but it is principally obtained in Brazil and Ceylon from the alluvial deposits of rivers. Though not much employed in jewellery, the Chrysoberyl sometimes forms a beautiful stone almost equal in appearance to the yellow diamond. The Chrysoberyl of the ancients was a different stone, probably the Chrysoprase of the moderns.

Chrysocchloræ (Gr. χρυσός, and χλωρός, *pale green*). A species of mole, *Chrysocchloris capensis*, inhabiting the Cape of Good Hope, the fur of which reflects most brilliant metallic hues of green and gold.

Chrysocolla (Gr. χρυσόκυλλα). A hydrated silicate of copper. The colour is verdigris or emerald-green, passing into sky-blue, and inclining to brown when impure; with a shining or dull resinous lustre, and opaque or only slightly transparent.

It occurs stalactitic, and massive, but oftener

CHRYSOMELA

investing Malachite and other ores of copper. It is found in Cornwall, in Cumberland, Westmoreland, Isle of Man, Leadhills in Scotland, Knockmahon and Audley mines in county Cork; also in Bohemia, the Banat, Hungary, Austria, the Tyrol, Saxony, the Harz, Siberia, Mexico, Chili, South Australia, &c.

The name Chrysocolla was given to this mineral by the ancients, because it was employed, along with silver and gold, in the soldering of the latter metal.

CHRYSOCOLLA. The Greek name for borax.

Chrysography (Gr. χρυσογραφία). The art of writing in letters of gold: a sumptuous fashion, practised by the writers of manuscripts, chiefly in the early part of the middle ages, when the leaves of parchment which contained the writing were also dyed with purple and other colours.

Chrysolite (Gr. χρυσόλιθος). The name applied to the paler and more transparent kinds of Olivine. It rarely occurs crystallised, but generally in angular or rolled pieces of a greenish or golden-yellow colour, embedded in basalt or lava. The principal localities are Vesuvius and the Isle of Bourbon, in lava; Real del Monte in Mexico, Upper Egypt, Constantinople, and in pale-green transparent crystals amongst the sand of a stream at Expailly in Auvergne. It is a silicate of magnesia and iron, and is sometimes used in jewellery. The stone called Chrysolite by the moderns is supposed to have been the Topaz of the ancients.

Chrysology (Gr. χρυσός, and λόγος, *discourse*). A name by which some Continental writers distinguish that branch of political economy which relates to the production of wealth.

Chrysomela (Gr. χρυσός, and μέλας, *black*). The name of a Linnean genus of Coleopterous insects, now the type of an extensive group, divisible into three families; viz. the *Chrysomelida* proper, characterised by having the antennæ remote from each other at the base; *Cassidida*, having the antennæ arising close together, but concealed at the base by the thorax; and *Galeracida*, having the antennæ close together at the base, but not concealed by the thorax. The characters which these three families possess in common are, a small body of an oval or rounded form; antennæ seldom so long as the body; legs of a moderate length, but rather thickened; and tarsi with the three basal joints dilated and spongy beneath, forming a kind of cushion. The insects of the present tribe are of sluggish habits, and feed upon the leaves of various vegetables, both in the larva and imago state, being characterised in the latter period by their brilliant metallic tints; whence their name. The larva of one of the British species (*Eumolpus vitis*, Fabr.) preys upon the young buds and leaves of the vine, and by its attacks upon the footstalk of the grape bunch so injures the nutrient vessels, as to cause the destruction or deterioration of the fruit. In the wine countries of Europe the

CHRYSOMELANE

ravages of this insect are often very serious, and much dreaded.

Chrysomelane. [PLEONASTE.]

Chrysopal (Gr. χρυσός, gold, and Opal). [CHRYSOBERYL.]

Chrysophanic Acid. *Rhaponticin, Rheio acid, Rhein, Rheumin, Rhubarbario acid, Rhubarbarin, Rumicin.* The colouring matter of various species of rhubarb and parmelia. It forms golden-yellow crystals.

Chrysoprase (Gr. χρυσόπρασος). An apple-green or leek-green variety of Chalcedony, found at Kosemütz in Lower Silesia, embedded in Serpentine, and at Belmont's lead mine, St. Lawrence county, North America. The colour is caused by oxide of nickel. It is much esteemed (on the Continent especially) as an article of jewellery, and is probably the stone called Chrysoberyl by the ancients.

Chrysorhamnia. The colouring matter of Persian berries. It occurs in acicular crystals.

Chrysotil. A fibrous variety of Serpentine, produced by the alteration of other minerals; Asbestos, Actinolite, Bronzite, &c. The colour is that of olive-oil, yellowish or brownish, with a metallic or silky lustre. It has been found in Anglesey, at Reichenstein in Silesia, and at New Haven in Connecticut.

Chunam. The name of a white cement, extensively used in the East Indies from the earliest period. It appears to owe its properties to the thorough hydration of all the parts of the mass; and in the interior of the country is said to be composed of a gravelly kind of limestone mixed with sand; but along the coast it is composed of shell lime and sea sand, mixed with 'jaggree,' or sugar water, which can only set on the condition that the ingredients are closely in contact with one another, and if the hydration has been effectually performed. Another kind of chunam is used for plastering, and takes a high polish; it consists of shell lime (without sand), yolks of eggs, and jaggree, beaten together with water in which the husks of cocoa-nuts have been steeped.

Church (possibly from the Gr. κυριακόν, from κύριος, lord; but this derivation is very doubtful). This word is used in various significations, answering to those of the Greek ἐκκλησία (Fr. église), which, from its original meaning of a *convened assembly*, is employed, 1st, to denote the whole body of true believers, or the visible church; 2nd, in addition to these, the spirits of the just made perfect, or the invisible church; 3rd, any congregation of Christians met together in a single place, or the body of believers resident in a town or district; and 4th, the edifice in which they meet for divine worship. To these we may add a fifth sense of the modern term *church*, when it is applied to a distinct religious community; as the Romish, the English, the Lutheran, &c. The true definition of the visible church has been a matter of much controversy. The English church, in her nineteenth article, explains it to be 'a congrega-

CHYLE

tion of faithful men, in which the pure word of God is preached, and the sacraments duly administered, according to Christ's ordinance, in all those things that of necessity are requisite to the same.' What these necessary requisites are is not dogmatically laid down, whence many communities come to be comprehended in the visible church by English divines which the Romish and other authorities exclude. Many sects, however, extend the pale still further, not considering the reception of the sacraments as any test of churchmanship, but referring it solely to the earnest belief and moral conduct of individuals.

CHURCH. In Architecture, a building dedicated to the performance of Christian worship. Under the article ARCHITECTURE, an account is given of the basilicæ which were first used for the assembly of the early Christians for this purpose, to which the reader is referred. Among the first of the churches was that of St. Peter's at Rome, erected about 326, nearly on the site of the present church; and it is supposed that the church of St. Sophia at Constantinople was built somewhat upon its model. That which was afterwards erected by Justinian seems, in its turn, to have served as the model for St. Mark's at Venice, which was the first church constructed in Italy with pendentives and a dome; the former furnishing the means of covering a square plan with a hemispherical vault. The five most celebrated churches in Europe erected since the period known as the Renaissance are: St. Peter's at Rome, which stands on an area of 227,069 feet; St. Maria dell' Fiore at Florence, which stands on 84,802 superficial feet; St. Paul's, London, which stands on 84,026 superficial feet; St. Isaac's, Petersburg, which stands on 68,845 superficial feet; and St. Geneviève, Paris, which stands on an area of 60,287 superficial feet. The churches are usually classed as follows in all countries where distinctions are recognised in them: *pontifical*, as St. Peter's at Rome, where the Pope occasionally officiates; *patriarchal*, where the government of the church is vested in a patriarch; *metropolitan*, when it is the see of an archbishop; *cathedral*, where a bishop presides; *collegiate*, when the building in question is attached to a college; *parochial*, when it is attached to a parish; and *conventual* when it is attached to a convent.

Chusite (from the Greek χύω, to pour or fuse; from its fusibility). An altered Chrysolite found in small yellow masses in the basalt of Limbourg.

Chyasic Acid. From the initials of carbon, hydrogen and azote. A term applied to the compounds of hydrocyanic acid.

Chyle (Gr. χυλός). The nutritious fluid prepared from the chyme, and imbibed by the lacteals to be conveyed to the thoracic duct and venous system. It contains about 10 per cent. of solid matter. In most mammals it is white; in birds transparent, except in some that live on ants and insects, as the woodpecker, which has been observed to be opaque; it is white in

CHYLE-CORPUSCLES

the crocodile, but colourless and transparent in other reptiles and in fishes.

Chyle-corpuscles. Cells developed in chyle of a subspherical form, greyish white colour, about $\frac{1}{2500}$ of an inch in diameter, often tuberculated on their surfaces. When found in the blood they are called *white corpuscles*.

Chylopoietic (Gr. *χυλός*, and *ποίησις*, *I make*). Organs concerned in the formation of chyle; hence the stomach, duodenum, and liver are termed *chylopoietic viscera*.

Chyme (Gr. *χυμός*, *juice*). The pulpy layer of digested matter which adheres to the inner surface of the intestine, and yields the chyle by admixture with the biliary secretion.

Chymistry. [CHEMISTRY.]

Ciborium (Lat.). In Architecture, an isolated erection, open on each side, with arches, and having a dome of an ogee form supported by four columns. It is placed on the altar of Roman Catholic churches, and contains the Host, or consecrated wafer.

Cibotium (Gr. *κισβός*, *a chest or coffer*). A genus of Ferns, one species of which is the Baranetz or Scythian Lamb, of which travellers have told strange tales. This plant is known as *C. Baranetz*, and its rhizomes may be cut so as to assume a quaint resemblance to some small animal. The silky hairs which envelope the crown of this, and probably some other allied plants, are collected under the name of Penghawar Djamba, and employed in medicinal practice as a styptic. A similar hair-like substance, known as Pulu, obtained in the Sandwich Isles from other species of the genus, is used for stuffing mattresses.

Cicada (Lat. *a grasshopper*). The name of a Linnæan genus of insects, celebrated in all ages for their powers of song or shrill chirp.

Et cantu querulæ rumpent arbusta cicadæ,
(*Georgics* iii.)

sings Virgil; which Dryden renders,

When creaking grasshoppers on shrubs complain:

although it is evident that Virgil refers to the insects of the present genus, which habitually frequent shrubs and trees, and feed on their juices, having a peculiar apparatus for piercing the bark and sucking out the juice. They are therefore more accurately described by Lord Byron as

The shrill Cicadæ, people of the pine.

The *manna* of the shops is the inspissated juice of the *Fraxinus Ornus*, poured out from the wounds inflicted by the *Cicada orni*. The organ of sound is peculiar to the male, and is situated on each side of the under and anterior part of the abdomen. The insects referable to the Linnæan genus *Cicada* are now separated into three families, *Cicadidæ*, *Fulgoridæ*, and *Cercoptidæ*.

Cicatrix (Lat.). The scar which remains after the skinning over of a wound.

Cicer (Lat.). A leguminous genus related to *Ervum*, one of whose species, *C. arictinum*, is much grown as a pulse in India and other

CICISBEO

Eastern countries, under the names of Chick-pea and Gram.

Cicerone (Ital.). A name originally given by the Italians to those persons who pointed out to travellers the interesting objects with which Italy abounds; but applied universally at present to anyone who acts as a *guide*. This application of the term *cicerone* has probably its origin in the ironical exclamation, 'E un Cicerone' (he is a Cicero), referring to the well-known garrulity of the Italian guides.

Cichoraceæ (Cichorium, one of the genera). One of the three great divisions of *Compositæ*, a very extensive order of herbaceous or shrubby Exogens. The plants belonging to this division have a milky juice, and form a connecting link between *Compositæ* and *Campanulaceæ*. They inhabit the whole world, and are characterised by all the florets of the flower-heads being alike and ligulate. Lettuce, Succory, and Endive are familiar examples of *Cichoraceæ*, which are generally bitter, with a soporific quality resembling that of opium. The Cichoraceæ are synonymous with the *Ligulifloræ*.

Cichorium (Gr. *κίχора*). The Chicory or Succory genus, from which that division of the Composites with all the florets in the head strap-shaped takes its name. It contains the Endive, *C. Endivia*, a favourite salad plant; and the Chicory, *C. Intyhus*, which has coarsely-toothed pinnately lobed lower leaves, a tall stem with many blue flower-heads, and a long thickish fleshy root, which forms an article of cultivation, and has been largely employed for mixing with coffee. It possesses medicinal properties resembling those of the dandelion.

Cicindela (Lat. *a glow-worm*). A name applied by Linnæus to a genus of beetles, which is placed at the head of the order *Coleoptera* from the circumstance of the outer lobe of the maxillæ being converted into an additional pair of feelers, called internal maxillary palpi. The mandibles are very strong and armed with strong teeth; the maxillæ are terminated by a movable spur; the eyes are large and prominent; and the wings generally well-developed. Endowed with such powers of perception, locomotion, and destruction, it may readily be inferred that these insects are a cruel and predatory race. Like the carnivora of a higher class, they are remarkable for the beauty of their colours, and were termed by Linnæus the tigers of the insect world. The species referable to the Linnæan *Cicindela* are extremely numerous, and are divided into twenty subgenera, of which one only is British, and to this the term *Cicindela* is restricted.

Cicisbeo (Ital.). A word synonymous with *cavaliere servente*, and applied to a class of persons in Italy who attend on married ladies with all the respect and devotion of lovers. This practice is now on the decline. Though the office of a *cicisbeo* has been the subject of frequent invective, it has not been without its advocates and admirers. Among

others Baretta, in his *Account of the Manners &c. of Italy*, vol. i. c. viii., ascribes it to a spirit of gallantry derived from the ages of chivalry, and much refined by the revival of the Platonic philosophy in Italy about the thirteenth century, and by the verses of Petrarch and his many imitators.

Oicocnia (Lat. *a stork*). A genus of wading birds of the tribe *Cultrirostris* of Cuvier; including the white stork (*O. alba*), the black stork (*O. nigra*), and the American stork (*O. Magneri*).

Oicenta (Lat.). A poisonous genus of the *Umbellifera*, one species, *C. virosa*, found in wet places in this country, being known as the Water Hemlock. The fruit is roundish, crowned with the calyx teeth, each half marked with five scarcely prominent ridges, and having a single oil-channel under each furrow. It is a hollow-stemmed herb, with tripinnate or bipinnate leaves having long narrow leaflets. The large fleshy rootstock is also very poisonous.

Cid (Arab. *seid*, *lord*). The name given to an epic poem of the Spaniards which celebrates the exploits of their national hero, Roderigo Diaz, count of Bivar, whose name Campeador reappears in the English CHAMPION [which see]. It is supposed to have been written in the thirteenth century, about 160 years after the hero's death; but unfortunately the author's name has not been transmitted to posterity. (Southey's *Chronicle of the Cid*.)

Cider (Fr. *cidre*). A fermented liquor made from the juice of apples. Cider is made in all the temperate climates of the world which are not sufficiently warm for maturing the grape, and where the cold is not so great as to confine the inhabitants to the beer produced by a fermented decoction of grain. Cider is formed by grinding or crushing the apples when ripe, either in a circular stone trough by a stone roller turned by a horse (which is the common practice in Worcestershire, Herefordshire, &c.), or between fluted or spiky, and afterwards between smooth rollers of wood or iron, driven by men (as practised in Devonshire, and in most places where cider is made on a small scale). The apples, including the core and the seeds, having been reduced to a pulp by crushing or grinding, the mass is put into hair-cloths and powerfully pressed; and the liquor which runs from it is put into casks, where it is allowed to ferment, the casks being freely exposed to the air in the shade. The progress of the fermentation is then carefully watched, and as the sediment subsides, the liquor is racked off; on the proper time being chosen for doing this depends the excellence of the cider. The best cider, other circumstances being the same, is that in which the fermentation has gone on slowly, and where the vinous fermentation has not gone so far as to become acetous. The check to fermentation consists in racking off from one cask to another. Before winter the casks are removed to a cellar, and by the following spring the liquor is fit for use, or for bottling. The principal cider counties in

England are Worcestershire, Herefordshire, and Devonshire. The Worcestershire and Herefordshire cider will keep from twenty to thirty years; while the best Devonshire cider will rarely keep more than five or six years.

Cilia (Lat. *eyelashes*). The hairs which grow from the margin of the eyelids. The term is also applied to microscopic filaments or plates which project from animal membranes and are endowed with quick vibratile motion. In most of the lower animals the respiratory function is effected by means of the vibratile cilia; many animalcules and the gemmules of the Acrites move by a similar mechanism; and it has recently been ascertained that vibratile cilia have a share in the performance of some important functions in the highest classes of the animal kingdom, where they have been detected on the membrane lining the female generative and respiratory passages, and the ventricles of the brain.

CILIA. In Botany, long hairs situated upon the margin of a vegetable body, as on the leaves of the *Sempervivum tectorum*.

Ciliary (Lat. *cilium*). The *ciliary ligament* of the eye is the circular portion that divides the choroid membrane from the iris, and which adheres to the sclerotic coat. The *ciliary processes* are the white folds at the margin of the *uvea* in the eye, which proceed from it to the crystalline lens.

Ciliated (Lat. *cilium*). In Botany, a term used in describing the surface of an organ, to denote the presence at the margin of fine hairs resembling the eyelash, as in the leaves of *Lurula pilosa*.

Ciliograde, Ciliograda (Lat. *cilium*, and *gradior, I proceed*). The name of a tribe of 'calephans or sea-nettles, comprehending those which swim by means of cilia.

Cimex (Lat. *a bug*). A Linnæan genus of Hemipterous insects, now subdivided into the following families: *Pentatomida*, *Coreida*, *Lé-*, *Cyprida*, *Cimicida*, *Reduviida*, *Acan-*, *hida*, *Hydrometrida*. Each of these families includes several genera, and each genus comprises many species; in all, the mouth consists of one lengthened and jointed proboscis, including several fine sharp bristle-like processes, which are employed in wounding the vegetable or animal substances on the juices of which these insects feed. The bed-bug (*Cimex lectularius*) may be regarded as a type of this extensive tribe of insects.

Cimelite or Cimolian Earth. A variety of clay found in amorphous earthy masses, of a grey colour, in the island of Cimolos (now called Argentiera) in the Grecian Archipelago, by the people of which it is used as a substitute for fuller's earth, for cleaning cloths.

Cinchona (named after the countess of Chinchon). One of the most important genera of the whole range of the vegetable kingdom, a sanitary point of view, for several of its species yield the invaluable drug quinine. Cinchona, as its name indicates, is the type of the *Cinchonaceæ*, and consists of evergreen trees

CINCHONACEÆ

growing in the tropical valleys of the Andes. They have white or pinkish flowers in panicles, with salver-shaped corollas, an ovary crowned by a fleshy disc, a simple style, and a two-cleft stigma. The capsule contains winged seeds, and opens from below upwards. The more important species are *C. Calisaya*, *succirubra*, and *Condaminea*. The cultivation of *Cinchona* for a supply of quinine, which has been commenced both in the East and West Indies, appears likely to become a decided success.

Cinchonaceæ (*Cinchona*, one of the genera). A natural order of shrubby or arborescent Exogens, almost exclusively inhabiting the tropics and the hotter parts of the world, and formerly known under the name of *Rubiaceæ*. They are in some respects allied to *Compositæ*, from which their distinct stamens, bilocular or plurilocular ovary, small embryo, interpetiolar stipules, and inflorescence distinguish them. They are divided from *Apocynaceæ* by the aestivation of the corolla, the presence of stipules, and the inferior ovary. They are also very nearly related to *Caprifoliaceæ*, being only separated from them by their interpetiolar stipules. Powerful febrifugal properties in their bark or emetic properties in their roots are the great features of this order, the most important medicinal products of which are *Cinchona* and *Ipecacuanha*. Many of the genera are fragrant, and some possess great beauty, as *Gardenia*, *Luculia*, *Ixora*, *Bouvardia*, *Rondeletia*, and others. Coffee also is produced by *Coffea arabica*, a plant belonging to this family.

Cinchonic Acid or Kinic Acid. An acid found in combination with the alkaloids in the varieties of Peruvian Bark, or *Cinchona*: it is crystallisable, and represented by the formula $C_{14}H_{11}O_{11}, H.O.$

Cinchonidine. An alkaloid existing in small quantity in many cinchona barks, but abundantly in those of Maracibo and Bogota. It crystallises readily, and forms crystalline salts with acids.

Cinchonine. This alkaloid occurs with quinine in cinchona bark. It is separated from the latter by taking advantage of its smaller degree of solubility in alcohol, or of the greater solubility of its sulphate in water. It is volatile, crystallises in large prisms; and forms crystalline salts with acids.

Cincture (Lat. *cinctura*, a girdle). In Architecture, the ring, or fillet, at the top and bottom of a column, which divides the shaft from the capital, or from the base, is known by this name.

Cinder Bed. A part of the Middle Purbeck series entirely composed of oyster-shells. This is a very remarkable deposit, long known, and serving as a geological landmark. It is a marine bed lying among freshwater deposits, forming the termination of the great series of deposits of that middle secondary period to which so much of the physical geography of Western Europe and England is due. The cinder bed lies a little above the **DIST BED** of

CINNAMON

Portland. Immediately below it is a series of freshwater strata with many fossil shells of species not found in the rocks above, and silicious beds of chert passing into beautiful chalcedony are amongst them.

The whole series of beds connected with this deposit is of unusual interest in Geology as pointing to the condition of neighbouring land. [**OLIVITE** **SARNS** and **DIST BED**.]

Cinder Iron. The cinder from the refinery of iron, which often contains as much as 60 or 70 per cent. of iron, is sometimes mixed with the fresh ore at the melting furnaces; but the resulting material is of a very inferior character, and the pig iron so obtained is rough and uneven upon the surface, porous in its internal character, and very irregular in its powers of resistance. The refinery pig, which contains much cinder, is lighter in weight than ordinary metal, and the quality of the bars is always inferior to that obtained from the natural mine.

Cinematics. [**KINEMATICS**.]

Cingulum (Lat. a girdle). In Zoology, is technically applied to the neck of a tooth, or to that more or less distinct constriction which separates the crown from the fang. The term *cingula* is also given to the transverse series of bony pieces connected together by tegumentary flexile joints, as in the middle part of the armour of the armadillo.

Cinnabar. An Indian name given, according to Pliny, to a mixture of the blood of the dragon and elephant, and to other substances of similar colour. It is now exclusively applied to the red pigment called *vermilion*, and to the mineral of which the former is an artificial preparation. The ore from which the mercury of commerce is obtained is a protosulphide of mercury, composed, when pure, of 86·21 per cent. of mercury, and 13·79 of sulphur. The principal mines of this mineral are those of Idria in Carniola, and Almaden in Spain, but it is also abundant in China, at New Almaden in California, in Mexico, and in Tuscany.

Cinnamelin. A fragrant compound contained in balsam of Peru.

Cinnamic Acid. When the essential oil of cinnamon is exposed to air, it gradually absorbs oxygen and deposits crystals of cinnamic acid = $C_{15}H_7O_2, H.O.$ It much resembles *benzoic acid*, into which it is converted when mixed with bichromate of potash and sulphuric acid. This acid is found, together with benzoic acid, in Peruvian and in Tolu balsam, from the latter of which it is readily obtained.

Cinnamon (Gr. *κιννάμωμον*, Heb. *kinnâmoneh*). The bark of the *Cinnamomum seylanicum*, a lauraceous tree, native of Ceylon, whence the finest cinnamon is obtained; it is of an astringent and highly aromatic and warm flavour, and yields by distillation an extremely fragrant and pungent volatile oil, kept for pharmaceutical use under the name of *oil of cinnamon*. An inferior kind of cinnamon is often met with in commerce, which is remarkably deficient in flavour.

CINNAMON STONE

Cinnamon Stone. A variety lime-Garnet, of a clear cinnamon-brown color. It is very abundant in Ceylon, and is occasionally cut and polished for jewellery; in fact, most of the stones sold as Hyacinths are in reality Cinnamon Stones. It is a silicate of alumina and lime. In Scotland this stone is found at the limestone quarries at Glen Gairn in Aberdeenshire, and large crystals of a rich cinnamon colour are met with in a coarse crystalline Dolomite at Bun Beg, near Gweedore; at Kilranclagh, Wicklow, &c.

Cinnamyle. The supposed radical of oil of cinnamon, of which the oil is the *hydruret*. The formula of cinnamyle is $C_{18}H_7O_2$, and that of oil of cinnamon, $C_{18}H_7O_2 + H$.

Cinque Ports or Five Ports. The seaport towns of Dover, Sandwich, Hastings, Hythe, and Romney; to which three others were afterwards added, viz. Winchelsea, Rye, and Seaford. These towns are incorporated, with peculiar privileges; are under the government of a lord warden, to whom writs for the return of members to parliament from them are directed; and the members so returned are termed Barons of the Cinque Ports.

Cinquecento (Ital. for *five hundred*, and an abbreviation for mille cinquecento or *fifteen hundred*). In Painting and Ornament, this term is applied to designate the art styles of the sixteenth century, or such as were developed about or after 1500. In like manner the terms *trecento* and *quattrocento* denote art of the fourteenth and fifteenth centuries. The Cinquecento is the period of the highest perfection of the arts of the Revival.

Cipher (Fr. *chiffre*, Ital. *cifra*, perhaps from Arab. *cifr*, a *dot*). The symbol 0 in numerical notation, which has no intrinsic value, but serves to determine the local value of the other digits by which it may be accompanied in the expression of any number. [ARITHMETIC.]

CIPHER is sometimes used in common language to signify any arithmetical character; hence the verb *to cipher*, which signifies to perform an arithmetical operation.

Cipolin. A green marble with white zones, somewhat like the section of an onion.

Cippus (Lat.). In Roman Antiquities, a name applied to sepulchral monuments which consisted of a small column whether round or rectangular.

Circinate (Lat. *circino*, *I make circular*). In Botany, a term used in describing the revivification of flowers and the direction of plants in general, to denote those which are rolled spirally downwards, so that they are bent like the head of a crosier; as the shoots of young ferns, the inflorescence of Boraginaceous plants, the leaves of the Sundew, &c.

Circinus (Lat.). The Compasses: a constellation of four stars near the South Pole.

Circle (Lat. *circulus*, dim. of *circus*, a *ring*). According to Euclid, a circle is a plane figure contained by one line, which is called the circumference, and is such that all straight lines drawn from a certain point within the

CIRCLE

figure to the circumference are equal to one another. The point which possesses this property is called the centre of the circle. The straight line and the circle are the only figures admitted into plane or elementary geometry, all questions in that branch of mathematics depending on the intersections of straight lines with straight lines, of straight lines with circles, or of circles with circles. This distinction was established by the ancient geometers, who regarded the other geometrical figures as formed by the intersections of planes with solids, and thence denominated problems for the solution of which the properties of other figures than the straight line and the circle were required, *solid problems*. In modern geometry, however, a circle is classed, with the conic sections, amongst quadrics or curves of the second order which have the property of cutting every line in two real or imaginary points. The principle of continuity leads us to regard the infinitely distant points of a plane as situated upon one and the same right line, and all circles as quadrics which pass through the same two fixed imaginary points on this line at infinity; these points are called the *circular points* at infinity. To explain this, it may be remarked, in the first place, that the equation $\frac{x}{a} + \frac{y}{b} = 1$ of a

line assumes the paradoxical form $1 = 0$ when the intercepts a, b , determined by the line on the coordinate axes, increase indefinitely; in other words, $k = 0$, where k is a linear constant, must be regarded as the equation of the line at infinity. But by giving suitable values to A, B, C , the equation of any circle whatever may be written in the form

$$x^2 + y^2 - r^2 + k(Ax + By + C) = 0,$$

which clearly intersects the line at infinity ($k = 0$) in the same imaginary points in which that line is intersected by the circle $S = x^2 + y^2 - r^2 = 0$ around the origin. Hence two circles, like every other pair of quadrics, may be regarded as intersecting one another in four points, two of which always coincide with the imaginary circular points at infinity.

In a similar manner we may regard two concentric, and therefore non-intersecting circles, as having double contact with each other at the circular points at infinity. For in general, if $S = 0$ represent the equation of a quadric, and $L = 0, M = 0$ those of two right lines, $S + LM = 0$ will be the equation of another quadric passing through the four intersection points of L and M with S , and if L and M coincide $S + L^2 = 0$ will represent a conic touching S in the two points in which L intersects S . If S represent a circle, and L the line $k = 0$ at infinity; then $S + L^2 = 0$ will be a circle having double contact, at the circular points, at infinity, with $S = 0$. But these equations clearly belong to concentric circles, since they only differ in their absolute terms.

The rectification of the circle, or the determination of the ratio of the circumference to the diameter, is a problem which has exercised the ingenuity of mathematicians in all ages.

CIRCLE OF CONTACT

It cannot be expressed in finite numbers; but numerous series have been invented from which it may be computed to any required degree of precision. Archimedes, in his treatise *De Dimensione Circuli*, proved that if the diameter is expressed by 7, the circumference is very nearly 22. A nearer ratio, which is generally used in ordinary measurements, is 113 to 356; and it has the advantage of being easily remembered, the numbers being formed of the three first odd numbers, each repeated. Vieta carried the approximation to 10 places of figures, and Van Ceulen to 36. Mr. Abraham Sharp computed the ratio to 72 places of figures; De Lagny, in the *Memoirs of the Academy of Sciences of Paris*, to 128; and lastly Dr. Clausen, in Schumacher's *Astronomische Nachrichten* (No. 589), to 250 places. Supposing the diameter 1, the first 36 figures by which the circumference is expressed (the ratio found by Van Ceulen) are 3·14159,26535,89793,23846,26433,83279,50288

The ratio of the circumference to the diameter of a circle is invariably denoted by the Greek symbol π . The area of a circle may be easily shown to be equal to that of a triangle whose base is the circumference and whose altitude is the radius. It is therefore expressed by πr^2 and, like π itself, can only be determined approximately; hence the impossibility of squaring the circle. Since the invention of the infinitesimal calculus, the discovery of convergent series for the rectification and quadrature of the circle is a matter of comparative facility. A number of such may be seen in all works on Trigonometry, and especially in Euler's *Introductio in Analysin Infinitorum*.

Circle of Contact or Osculating Circle. The circle which fits closest to any given curve at a given point. A circle being determined by three points, we can only demand from it that it shall have three consecutive points in common with the curve; the contact, therefore, will in general be *three-pointic*, or of the *second order*. In general, the circle of contact will cut the curve. [CONTACT; OSCULATION.]

Circle of Curvature. The circle whose curvature, or amount of bending, is the same as that of a given curve at any given point. [CURVATURE.] It is the same as the *circle of contact or osculating circle*.

Circle at Infinity, Imaginary. The imaginary circle in which the plane at infinity is intersected by every sphere. If $S=0$ represent the equation of any given sphere, that of any other sphere may obviously be written in the form $S + kL = 0$, where k is a linear constant, and $L=0$ is the equation of a plane. These two spheres clearly intersect in two circles one of which lies in the plane $L=0$, the other being the intersection of $S=0$ with the plane $k=0$ at infinity. The latter circle, consequently, is common to every sphere.

Circle, Six-points. The circle which passes through the middle points of the sides of a triangle. It passes also through the feet of the three perpendiculars let fall from the angles upon the opposite sides, and possesses

CIRCULAR INSTRUMENTS

many very remarkable properties. The same circle is referred to by Continental writers as the *nine-points circle*, since, besides the six points already named, the middle points of the three lines joining the corners of the triangle to the intersection of the three perpendiculars also lie in its circumference. Feuerbach, Brianchon, Poncelet, Steiner, and many others, have investigated the properties of this circle. The first of these geometers, in his *Eigenschaften des Geradlinigten Dreyecks*, &c. (Nürnberg, 1822), discovered that it touched the inscribed, as well as the three escribed circles of the triangle, a property which was afterwards generalised by Sir W. Hamilton, Dr. Hart, and others. (*Quart. Journ. of Math.* vol. iv. p. 245.)

Circuits (Lat. circuitus, a going round). In England, Scotland, and Ireland, divisions of the kingdom appointed for the judges of assize; two of whom go each circuit twice a year, to deliver the gaols and try issues at nisi prius. England is divided into six circuits—Home, Midland, Oxford, Norfolk, Western, Northern; Wales into the North and South Welsh circuits. A single judge travels each of the Welsh circuits, and these two meet at Chester to transact the business of that county. The judges choose their own circuits; the three chiefs, and the puisne judges, in order of seniority, making their election. The circuits are after Hilary and Trinity Terms, and vary in their duration from three to seven or eight weeks; but a third or winter circuit is usual in some of these divisions. [COURTS, SUPERIOR AND ASSIZE.] The circuit or assize towns in most counties have been fixed by immemorial usage, but some changes have been made by the authority of the Privy Council. Barristers at the common-law bar choose their circuits on first embarking in their profession, and etiquette allows of only one subsequent change. Ireland is also divided into six circuits, and in Scotland assizes are held periodically in the principal towns.

Circular Cubic. A cubic or curve of the third order which passes through the circular points at infinity. It bears the same relation to a general cubic that a circle does to a quadric. [CIRCLE.] The general form of the equation of a circular cubic is $(x^2 + y^2)L = kS$, where $S=0$ denotes a quadric, L a linear function of the coordinates, and k a linear constant. (Salmon's *Higher Plane Curves*.)

Circular Functions. This term, as generally employed, is synonymous with trigonometrical functions.

Circular Instruments. The name given to any astronomical or nautical instrument for measuring angles, in which the graduation extends round the whole circumference, or to 360°. Formerly it was thought sufficient to carry the divisions over a portion of a circle only, whence the quadrants, sextants, and octants, once so common; but experience has shown that entire circles (especially where the instruments are of considerable size) have a great advantage over graduated segments; and

CIRCULAR PARTS

hence, excepting the *sea-sexant*, the latter are now seldom used. The principal circular instruments used in astronomy are *altitude and azimuth circles*, *mural circles*, *reflecting circles*, and *repeating circles*. The altitude and azimuth circle, as its name implies, is used for measuring the altitudes and azimuths of stars; it is consequently composed of two graduated circles, one vertical and the other horizontal. This is a sort of universal instrument, being applicable to almost all the purposes of astronomy. The *mural circle* is so called because it is supported by means of a long axis passing into a wall, the plane of the circle being parallel to the wall. The instrument is placed in the meridian, and is used for determining the polar or zenith distances of celestial objects.

[**MURAL CIRCLE.**] The *reflecting circle* carries a mirror, by means of which an object is seen by reflected vision; another object is viewed directly; the two are brought to coincide, and the angular distance between them is measured by the inclination of the mirror to the axis of the telescope. [**SEXTANT.**] The *repeating circle* or *multiplying circle* is so contrived that the observer is enabled to repeat or multiply the observation, by reading it off successively on different parts of the graduated limb. A number of values being thus found, the mean of the whole is taken as the correct result. This instrument is sometimes called *Borda's circle*, from the name of its improver. [**REPEATING CIRCLE.**]

Circular Parts. In Spherical Trigonometry, the name given to two rules, invented by Lord Napier, and demonstrated in his *Mirifici Logarithmorum Canonis* (see also Todhunter's *Spherical Trigonometry*), for obtaining the formulas relative to a right-angled spherical triangle. In any right-angled spherical triangle, let a and b denote the sides, c the hypotenuse, and A and B the angles opposite to a and b respectively. Take the two sides, and the complements of

the hypotenuse and of the two angles, and write them in order round a circle, as in the annexed diagram; then, if any one part be called the *middle* part, the two next to it the *adjacent* parts, and the other two the *opposite* parts, the two following rules will hold good:—

1. The sine of the *middle* part is equal to the product of the tangents of the *adjacent* parts. 2. The sine of the *middle* part is equal to the product of the cosines of the *opposite* parts. Thus—

$$\sin a = \tan b \tan (90^\circ - B) = \tan b \cot B.$$

$$\sin c = \cos (90^\circ - A) \cos (90^\circ - C) = \sin A \sin C.$$

Circular Points at Infinity. The two imaginary points in which any circle intersects the infinitely distant right line in its plane. [**CIRCLE and LINE.**]

Circulating or Recurring Decimal. A decimal in which certain digits are continually repeated. Thus $.15723723 \dots$ *ad inf.* is a circulating decimal, of which the figures 723

CIRCUMCISION

constitute the recurring period. For brevity, such a decimal is written thus $.15723$, the points over the 7 and 3 indicating the period. A recurring, or else a finite, decimal is always obtained when attempting to convert a common fraction to a decimal; and conversely, every recurring decimal can be expressed as a fraction, the numerator of which is the difference of the numbers formed, respectively, by taking all the digits up to the first and up to the second periods, and whose denominator consists of as many digits 9 as there are digits in the period, followed by as many ciphers as there are digits in the non-recurring part of the decimal. Thus, in the above example, the equivalent fraction is $\frac{15723 - 15}{99900} = \frac{15708}{99900}$.

Circulation of the Blood. The passage of the blood through the various tissues of the body. In warm-blooded animals, the heart is divided into four cavities: two auricles and two ventricles. The circulating venous blood enters into the right auricle by and from the two *vena cava*, inferior and superior. Thence it passes into the right ventricle, whence the blood, still venous, is forced by the pulmonary artery into the lungs. The contact of the oxygen contained therein, admitted through the trachea, and ramified through the bronchial tubes over the whole extent of the lungs, changes the blood from venous to arterial. This scarlet blood is returned from the lungs by the pulmonary veins, entering the left auricle, and subsequently the left ventricle. Thence it is driven through the *aorta* into the arteries, and distributed by the capillaries to the various tissues. The veins then once more collect the blood, and return it by the *vena cava* to the heart. In reptiles there is but one ventricle, and the mixed blood contained therein is transmitted partly into the lungs, and partly into the body. In Crocodilia a partial partition divides the ventricle. In fishes only two cavities exist: an auricle and a ventricle; and consequently only venous blood is received and transmitted. [**BLOOD.**]

Circumcellitones (Lat. from *circum*, and *cella*, a house). In Ecclesiastical History, an African sect of the fourth century, so called from their habit of begging from door to door. They asserted the civil equality of all men, and, carrying to an extreme the tenets of the Donatists, were specially conspicuous in their eagerness for martyrdom, which, in default of persecutors, they often inflicted on each other. (Milman's *History of Christianity*, book iii. ch. i.)

Circumcision (Lat. *circumcisio*). The initiatory rite of the Jewish covenant. This custom has been long prevalent among Eastern nations. Herodotus refers to it as the practice of the Egyptians and Ethiopians, and as borrowed from them by the Phœnicians and Syrians. It is enforced by the Koran upon all the disciples of Mohammed, whether from an idea of cleanliness, or merely as a distinguishing rite.

CIRCUMFERENCE

Circumference. The curved line which encloses a plane space. The broken line which encloses a rectilinear figure is usually distinguished as the *periphery*. The latter term is derived from the Greek words *peri* and *phero*, the former from the synonymous Latin words *circum* and *fero*.

Circumferentor. An instrument used by surveyors for taking angles. It consists of a graduated brass circle, and an index all of one piece, and carrying a magnetic needle suspended above the centre of the circle. The index being directed to an object, the angle which it makes with the magnetic meridian is noted. The index is then directed to the second object, and the angle it makes with the same meridian observed in like manner. The difference (or sum, as the case may be) of the two observed angles gives the angle between the two objects. It is evident that only a very rough approximation can be obtained in this manner. For the purposes of surveying, a pocket sextant is a far preferable instrument.

Circumflexus (Lat.). A muscle of the palate; the term is also applied to arteries which wind round bones or joints.

Circumpolar Stars. Stars which, at any given place, move round the pole, or complete their diurnal circles, without setting. The number of stars so circumstanced increases with the latitude of the place or the elevation of the pole above the horizon.

Circumscissile (Lat. *circumscindo*, *I cut round*). A mode of dehiscence observed in the fruit of some plants; it occurs by a transverse circular separation of the sides of the ovary, as in *Anagallis* and *Hyoscyamus*.

Circumscribed Figures. [INSCRIBED AND CIRCUMSCRIBED FIGURES.]

Circumscription (Lat. *circumscriptio*). In Botany, the line representing the two edges of a leaf, or other organ, i.e. its margin.

Circumvallation (Lat. *circum, about*, and *vallum, a rampart*). In Fortification, an intrenchment thrown up by an investing army, facing outwards from the place invested, to resist attacks from the field, is called a 'line of circumvallation.'

Circus (Lat.). A long, straight, and narrow building, whose length is to its breadth as five to one. It was divided down the middle in the examples which have survived by an ornamental barrier called the *spina*, and this class of building was used by the Romans for the exhibition of public spectacles and of chariot races. There were several of these structures at Rome, of which the most celebrated was the Circus Maximus, which was altered and improved by Julius Cæsar, and was by him supplied with water to allow of its serving occasionally as a naumachia. Augustus added to it the celebrated obelisk now standing in the Piazza del Popolo; but no vestiges of the circus itself remain. Besides this one, there were at Rome the circi of Flaminius, near the Pantheon; the Agonalis, occupying the site of what is now the Piazza Novana; that of Nero, on a portion of which St.

CISSOID OF DIOCLES

Peter's now stands; those of Flavius Antoninus and Aurelian, no longer even in ruins; and that of Caracalla, which was 738 feet in length, and is still sufficiently perfect at the present day to exhibit its plan and distribution in the most satisfactory manner. Some remains of circi are also visible at Bovillæ, Orange, and at Tarragona, and portions of a *circus maritimus* exist at Anagnina.

The spectacles exhibited in the circus were called the Circensian Games, and they consisted chiefly of chariot and horse races. The Romans, and the Greeks of the lower empire, were passionately fond of them, and particularly so of the chariot races, which often excited so much interest in the time of the emperors as to divide the whole of the inhabitants of the cities into factions, known by the name of the colours worn by the different charioteers. The disputes of these factions sometimes led to serious disturbances, and even occasionally to bloodshed.

Cirripeds, Cirripedia (Lat. *cirrus*, and *pes, a foot; curly-footed*). A class of fixed homöogangliate animals, characterised by having a number of long curled articulated setigerous processes, analogous to the feet of the Crustaceans, which project from the central aperture of the multivalve shell protecting the body. These animals are commonly called Barnacles and Acorn-shells. [LEPADITES and BALANITES; BARNACLE GRASS.]

The following classification has been generally adopted:—

Order 1. Thoracica. Sub-order: Balanidae (Acorn-shells).

Families: Balaninæ, Cthamalinæ.

Sub-order: Verrucidae.

Sub-order: Lepadidæ (Barnacles).

Order 2. Abdominalia.

Order 3. Apoda.

Cirrostratus (Lat. *cirrus*, and *stratus, bed or covering*). The *wane cloud*, intermediate between the Cirrus and Stratus. The *mackerel sky* of a summer evening, which is regarded as foreboding rain, is a modification of this cloud. [CLOUD.]

Cirreus (Lat. *cirrus, a lock of curled hair*). In Botany, a term used in describing the apices of bodies, to indicate those that are terminated by a spiral or flexuose filiform appendage (*cirrus*), arising from an elongation of the costa, as in the leaf of *Gloriosa superba*. It is also applied to modifications of the branch, the inflorescence, the petiole &c. when such parts assume the state of a twisting body, which enables the plant belonging to it to raise itself upon neighbouring objects.

Cirrus (Lat.). The curl-cloud or mare's-tail.

Circeole (Gr. *κίρκη, a dilated vein*, and *κύμα, a tumour*). A morbid enlargement of the spermatic veins in the groin.

Cissoïd of Diocles (Gr. *κισσοειδής, like ivy*). A curve invented by the Alexandrian mathematician Diocles with a view to the solution of the famous problem of the duplication

of the cube, or the insertion of two mean proportionals between two given straight lines. The curve is described as follows:—

From A, one of the extremities of the diameter of a circle, draw a straight line, AC (or Ac), to meet the tangent through the other extremity, B, and make CP (or cp) equal to the intercepted chord AD (or Ad); the points P (and p) will trace the cissoid.

Taking A as origin of rectangular coordinates, and AB as abscissa axis, the equation of the curve is easily found to be $x^3 = (a - x)y^2$, a being the diameter of the generating circle. The cissoid, therefore, is a cubic curve of the third class, having a cusp at the origin, and a point of inflexion at infinity, at which the tangent is the asymptote cC. It also passes through the circular points at infinity, so that of its three foci two coincide. It may, moreover, be regarded as the pedal of a parabola with respect to the vertex; in other words, it is the locus of the vertex of a parabola which rolls upon an equal parabola, so that corresponding points of the curves always coincide with their point of contact; it is also the inverse of a parabola with respect to its vertex. Another remarkable property of the cissoid is, that the whole space lying between the double branches and the asymptote is equal to triple the area of the generating circle. A method of describing the cissoid mechanically by the motion of a rectangular rule, is given in Newton's *Universal Arithmetick*.

Cist (Lat. *cista*; Gr. *κίστη*). In Architecture and Sculpture, a chest or basket. It is a term usually applied to the mystic baskets employed in processions connected with the Eleusinian mysteries. They were originally of wickerwork, and when afterwards made of metal the form and texture were preserved in imitation of the original material. When sculptured on antique monuments, it indicates some connection with the mysteries of Demeter (Ceres) and Dionysus (Bacchus).

Cistaceæ (Cistus, one of the genera). A natural order of shrubby or herbaceous Exogens inhabiting chiefly the countries of the South of Europe and North America. They are distinguished from *Violaceæ* by their indefinite stamens and inverted embryo; from *Bisacææ* by the last character, by their mealy albumen, their habit, and by never having their leaves dotted; from *Hypericaceæ* by the latter character, and the structure of the fruit. They are allied to *Papaveraceæ* by the genus *Dendromecon*; but their true station appears to be in the vicinity of *Linaceæ*, to which they approach by the genus *Lechea*. They are often plants of great beauty, but possess no sensible properties, excepting the *Cistus creticus* and a few others, which yield the resinous balsamic substance called *gum labdanum*.

Cisterciens. In Ecclesiastical History, a monastic order deriving their name from

the abbey of Cîteaux, which was founded by Stephen Harding (an Englishman, who had been a monk at Molesme in Burgundy) at the close of the eleventh century. In discipline, this order was a reform of the Benedictine rule, and amongst its earliest and most celebrated members was St. Bernard.

Citadel (Ital. *citadella*, dim. of *citta*, a city) A strong fort, constructed within fortifications, and intended as a last place of defence for a garrison.

Citation (Lat. *citatio*, from *cito*, I summon). In Ecclesiastical Law, an act whereby the defendant, on the application of the plaintiff, is commanded to appear in court on a certain day in order to enter into a suit. In the Civil Law, reference to an authority or precedent in the course of a pleading is termed a *citation*; and hence the common use of the word in the same sense with *quotation*, *allegation of instances*, &c.

Citraconic Acid. One of the products of the action of heat upon citric acid.

Citramide. The product of the action of ammonia on citric ether.

Citric Acid, Citric Acid, Citridic Acid. Acids derived from the *Citric Acid*, and identical or isomeric with the *Citraconic*, *Itaconic*, and *Aconitic* acids.

Citric Acid (Lat. *citrus*, the lemon). The pure acid part of lemon and lime juice; it is also found in other fruits. Crystallised citric acid is largely prepared for domestic use.

Citridic Acid. [ACONITIC ACID.]

Citrine Ointment. An ointment containing nitrate of mercury; it has a lemon-yellow colour. The *unguentum hydrargyri nitratis* of the Pharmacopœia.

Citronyl. *Citrene*. A hydrocarbon composing the greater portion of oil of lemons.

Citrullus. The well-known cathartic drug called *colocynth* is furnished by a species of this genus, *C. Colocynthis*. The genus is known by its unisexual flowers, and the persistent five-parted calyx and corolla, the male flowers with five stamens united in three bundles, and the females with a three to six-celled ovary, a cylindrical three-cleft style, and kidney-shaped stigmas. The drug obtained from Spain, the Levant, &c. consists of the round fruits or gourds, the pulp of which is light and spongy and intensely bitter.

Citrus (Lat.; Gr. *κίτρον*). The genus of the Orange, Lemon, Citron, Lime, Shaddock, and various other well-known fruits. It belongs to the *Aurantiacæ*, and is known by its cup-like calyx, its numerous stamens irregularly united by their filaments into several bundles, and its pulpy fruit with a spongy rind. The leaves are remarkable as being compound, yet having but one leaflet, jointed on to the leaf-like stalk. The Citron, *C. Medica*, furnishes some essential oils; the Lemon, *C. Limonium*, is used in medicine and for various domestic purposes; and the Orange, *C. Aurantium*, and the Shaddock, *C. decumana*, yield dessert fruits.

City (Fr. *cité*, Ital. *città*, Lat. *civitas*). A borough or town corporate, which is or has

been the seat of a bishop, or the capital of his see; and it differs in no respect but that of superior dignity from any other borough. Some cities and a few boroughs are counties in themselves.

Civet. A brown semifluid matter contained in a gland near the anus of the *Viverra Civet*, or *civet cat*: its odour is offensive unless extremely diluted, and then in combination with other perfumes it adds to their energy. The term *civet* is Arabic. When genuine, this matter is worth from 25s. to 35s. per oz.

Civil List. The term formerly applied to the list of all the expenses of the government, or 'of all the heads of public expenditure, excepting those of the army, the navy, and the other military departments;' but confined at present by the Act 1 & 2 Vict. c. 2 to expenses proper for the maintenance of her majesty's household. In England the civil list is fixed in the first session of parliament after the accession of the sovereign, and is then understood to be granted for the whole period of the reign.

Civilian. One learned in the Civil or Roman Law; particularly a member of the 'College of Doctors of Law exercent in the Ecclesiastical and Admiralty Courts' in England and Wales, in which courts the civil law is recognised. [LAW, CIVIL.] Practice as an advocate in those courts was confined to members of this college, who must have taken the degree of Doctor of Law in the university of Oxford or Cambridge; but a change was effected by the establishment of the Probate and Divorce Court, which was thrown open to barristers in general, in 1857.

Clairvoyance (Fr. *clair-sightedness*). This term is generally applied to that faculty which is claimed for certain persons under what are called mesmeric or magnetic conditions. This faculty amounts to a transference of the senses, enabling the possessor to read with his fingers or stomach, to see absent objects, to know things of which he has never heard, with other pretensions of even greater extravagance. The phenomena of clairvoyance have been minutely examined in the eighth edition of the *Encyclopædia Britannica* under the head of 'Somnambulism;' and the general result of the tests applied is to show that there is no magnetic influence or nervous fluid, which passes from the operator to the person operated on, and that all the recorded phenomena which rest on any trustworthy evidence can be accounted for on ordinary principles. It must, of course, be admitted that mere trickery and collusion on the part of its professors afford no sound reason for declaring that the pretended science of mesmerism has no real foundation whatever; but 'if it appears that in whatever, where clairvoyance is subjected to scientific scrutiny, it is able to establish its pretensions, we shall be justified in coming to the conclusion that it is nothing more than a gigantic swindle, and that its professors are no more than arrant impostors.' The spirit-

rapping mania, which has invaded this country from the United States, is only another form of the same delusion.

Clamp. In Brickmaking, a large mass of bricks, generally quadrangular in plan, and six, seven, or eight feet high, arranged in the field for burning, which is effected by flues prepared in stacking the clamp, and by lighting the breeze and cinders laid between each layer or course of bricks. Clamp-burnt bricks are very irregular in their quality; but there is a notable economy in the quantity of fuel required to prepare the same number of bricks as compared with kiln-burning.

CLAMP. In Joiner's work, a piece of wood fixed to another with a mortise and tenon, or a groove and tongue, so that the fibres of the piece thus fixed cross those of the subjacent piece, and thereby prevent it from *warping* or *casting*.

Clan (Gael. *clann*, *children* or *descendants*). The clans of the Scottish Highlands are tribes consisting of many families all bearing the same surname, which according to tradition descend from a common ancestor. But it is more probable that most clans were formed of an aggregate of different families, the inferior standing to the superior in the same sort of relation as the Roman clients to their patrons, and by degrees assuming the same name. Some clans, however, are divided into branches, each possessing a distinct surname. The chieftainship of every clan descends regularly through heirs male; but in the earliest times of their history the rights of primogeniture were not very distinctly defined. The Gaelic clans occupy the northern and western parts of the central shires of the country.

Claret (from Lat. *clarere*, *to be clear*). A name applied to several of the Bordeaux wines. [WINE.]

Clarinet (Ital. dim. of *clarino*). A wooden musical wind instrument, whose mouth-pieces of the trumpet form, and which is played by holes and keys: said to have been invented about the year 1600 by John Christopher Denner of Leipsic. Like the oboe, it is played with reed mouthpiece, though it is of somewhat different form. For its compass, see table at the end of MUSIC.

Classes (Lat.). In Ancient History, this term is particularly applied to the division of the Roman people said to have been made by Servius Tullius for the purpose of distributing them into centuries. [CENTURIES.]

Classic. In Antiquity, the Roman people were divided into classes, and the highest order were by preeminence termed *classici*. Hence the name came to signify the highest and purest class of writers in any language; although, down to a comparatively recent period, the term was used merely to denote the most esteemed Greek and Latin authors. Nothing marks more strongly the increased attention to, and appreciation of, modern literature, than the now universal application of the term to modern languages also, and the establishment

CLASSIC

in this manner of a line between those authors whom we regard as models and authorities in point of style, and those who are not so highly esteemed. The epithet *classical*, as applied to ancient authors, is determined less by the purity of their style than by the period at which they wrote. Thus we speak of the classical age of Greek or Latin writing. With respect to the former, the classical age begins with Homer, the earliest Greek writer with whom we are acquainted. The purest age of Greek classical literature may be said to end about the time of the Macedonian conquest, or about 300 B.C.; but, in a wider sense, it extends to the time of the Antonines, and embraces a much larger catalogue of authors; while the centuries subsequent to that time produced a few who by the purity of their style deserve to be ranked with earlier classics. The Latin classical period is shorter; its earliest writer is Plautus, and the language may be said to have lost its classical character about the same time with the Greek, i.e. the reigns of the Antonines; although this limit is arbitrary, and some later writers (even down to Claudian) are generally included among classics. Within the Latin classical era there is a more restricted period of the purest Latinity, comprising the age of Cicero and that of Augustus.

CLASSIC. In the Fine Arts, a term denoting that the principle of the arrangement of a subject is such as would have suggested itself to the minds of architects or artists of the early and the more decidedly classical period, in which the accessories or the parts of a design are suitable to its general character, and such that nothing can be introduced which does not strictly belong to the particular class under which it is placed.

Classification. In *Æsthetics*, an arrangement by which objects of the fine arts are divided into classes; as, for instance, in galleries of paintings the works should be arranged in schools, each school being subject to a chronological order of the masters. In *Numismatology*, the coins should be arranged by countries, and these again by the chronological order of the monarchs; and so with other branches of the arts.

Classification in Geology. The principles of classification in this science involve a reference to the circumstances under which rocks were originally formed, the nature of their accidental contents, and the changes they have undergone since they were formed. To identify rocks, we must do more than identify mineral condition, or even make out a few fossils; and to classify them properly, much minute knowledge of *Palæontology* is requisite.

The necessity of classification in Geology is evident, and its value in practice is considerable. Certain rocks in all countries serve as landmarks, some leading to the discovery of valuable minerals, others valuable in themselves; and to be able in a foreign country to identify by any means a rock whose position

CLASSIFICATION

in the general series is well ascertained, is to save a great amount of labour.

The principles of classification now universally adopted have reference to the inhabitants of the earth and sea at the time of each deposit, for it is found not only that each part of the earth has its own fauna and flora, but that each period of its history, marked by a group of deposits, is characterised in a similar manner. It is not indeed the case, as was once supposed, that particular species, whether of plants or animals, are sufficient to identify a rock. Careful study of the known groups and the comparison of collections, not merely of individual specimens, is usually required in doubtful cases; but the subject is reduced within a definite limit, and so much advance has already been made towards identification in distant parts of the world, that gaps will soon be filled up. [*PALÆONTOLOGY.*]

To the examination and comparison of fossils must be joined a knowledge of the mineral nature of each deposit. Limestones will nowhere be found to contain groups of shells *in situ* similar to those found in the clay of the same time and place. Animals delighting in sand will not multiply and become characteristic in mud. Remains of tribes inhabiting by preference deep water will not be mixed up with those from shallow water, provided of course the remains are found where the animal lived. But many fragments of dead animals must be drifted, and thus admixtures take place and apparent confusion follows, requiring the exercise of great discrimination and experience on the part of the palæontologist. Practically, a naturalist of higher order must avail himself of the labours of the naturalist who devotes his time to species, as it is necessary that he should be able to generalise before he can determine what is the true meaning of the *faunes* of a collection obtained from a clearly defined group of deposits.

Although the labour thus involved is great, the results are satisfactory, and an approach to a successive history of animated nature during all the changing events of the earth's transitions may ultimately be obtained. It is in fact now beginning to be made out. But it must not be supposed that such history can be perfect before the principles of classification are settled. They are still under discussion, and the result of enquiries and investigations up to the present time will be found in the article *DESCRIPTIVE GEOLOGY*.

After all enquiry is completed with regard to those rocks that generally or occasionally contain fossils, there must yet remain a large outlying group of crystalline and metamorphic rocks of all ages, very difficult to interpolate. Locally, this can often be effected by actual observation, and thus many basalts and granites, schists and quartz rocks are placed satisfactorily enough. But a minute study of their condition and the circumstances of their history has led to little result hitherto so far as concerns the identifying distant mineral accumulations of the same

nature not containing fossils. There are some basalts or outpourings of lava whose age is well known from their eruption having taken place between certain marked geological epochs, and some granites and crystalline schists similarly identified; but they differ little from others, more modern and more ancient, and no conclusion can be arrived at where fossiliferous rocks are not at hand.

Fossils therefore, and the science they involve, PALEONTOLOGY, must be regarded as the key to geological classification, and must be referred to accordingly.

CLASSIFICATION. In Natural History, denotes the arrangement or assortment of various objects into those several classes denoted by appellatives which are called *genera* and *species*. For classification in Botany, Zoology, Medicine, Chemistry, &c., see the separate articles.

Clausus (Lat. *clausus*, *shut*). A name given by Cuvier to a family of Acepñalous bivalves, comprehending those which have the mantle open at one end, or near the middle, for the passage of the foot, and prolonged at the opposite end into a double tube for respiration and excretion.

Clausilia (Lat. *clausus*). A genus of land-snails, so named because the aperture of the shell is closed internally by a spiral lid. Many species of this genus are natives of Great Britain. The rugose or dark close-shell (*Clausilia rugosa*, Drap.) is not uncommon at Charlton, where it may be found under stones. *Clausilia biplicata*, Leach, is found at Bat-tersea.

Clausthalite. A rare mineral generally resembling granular Galena. It is a selenide of lead in which part of the lead is frequently replaced by silver. It occurs in veins of Hæmatite at Clausthal (whence the name Clausthalite) and other localities in the Harz, near Freiberg in Saxony, and at the Rio Tinto mines in Spain.

Clavate (Lat. *clava*, *a club*). In Botany, club-shaped; as when a body is linear at the base, but towards the apex grows gradually broader.

Clavicle (Lat. *clavicula*, dim. of *clavis*, *a key*). The bone situated between the sternum or breast-bone and the acromion process of the scapula or blade-bone.

Clavus (Lat. *a nail*). The disease produced in grains of rye when they are changed to a brown or blackish colour by the action of a parasitical fungus called *Oidium abortivum*. These diseased seeds, called Ergot of Rye, or Spurred Rye, are a valuable agent in exciting uterine action during labour. A similar change occurs in other grasses; and, indeed, it is believed that the presence, often unobserved in pastures, of ergoted grasses is a fruitful source of mischief to cows in calf.

CLAVUS. A severe pain in the forehead, compared to the driving of a nail into the skull, has been called *clavus* by medical writers.

Claw or Ungula. In Botany, the narrow part at the base of a petal which takes the

place of the footstalk of a leaf, of which it is a modification.

Clay (A.-Sax. *clæg*). A term applied to a variety of natural earthy compounds, all of which are essentially characterised by *plasticity*. Chemically speaking, they are hydrated silicates of alumina, often largely mixed with other substances; but their important uses in agriculture and the arts are referred to the above silicates. Several minerals are definite crystalline silicates, which by disintegration or decomposition contribute to the formation of clay: common felspar is a silicate of alumina and potash; Al_2O_3 ; $3SiO_2 + KO$, SiO_2 ; it is one of the constituents of *granite*, and some of its varieties crumble, when exposed to the joint action of air and water, into a white clay: *Cornish clay* and the *Kaolin* of China are clays so formed, and may be represented as Al_2O_3 ; $3SiO_2 + 2HO$. Other clays are less pure, from the admixture of sand, oxide of iron, or carbonate of lime, substances which importantly modify their properties. The varieties of *marl* are calcareous clays; and the *coloured clays* generally derive their various tints from the oxides of iron. The presence of these and some other extraneous matters renders some clays very fusible: the pure aluminous silicates are nearly infusible, but when lime, magnesia, or oxide of iron, is present, they become more or less fusible or vitrifiable, in proportion to the quantity of these bases present in the clay. The varieties of *fire-clay* used for lining furnaces, and other similar purposes, are nearly pure silicates, $= Al_2O_3, 3SiO_2$, with mere traces of alkaline bases and oxide of iron. The different red and yellow *ochres*, and *bols*, are mixtures of clay and hydrated peroxide of iron; some of them contain oxide of manganese. *Fuller's earth*, used for the capillary absorption of greasy matters, is also a porous silicate of alumina. Clay has some remarkable distinctive properties: it exhales a peculiar odour when wetted or breathed upon, and when dry and applied to the tongue, it adheres to it, in consequence of the rapidity with which it absorbs moisture: it readily absorbs ammonia, and many other gases and vapours generated in fertile and manured soils; hence its agricultural value. The important quality of *plasticity*, upon which the manufacture of porcelain and pottery depends, belongs exclusively to aluminous combinations in their humid state, so that they admit of being turned in the lathe or upon the potter's wheel, or of being moulded into the infinite variety of useful and ornamental products of the ceramic art. These forms are rendered permanent by careful drying, and subsequent exposure to high temperatures.

CLAY. In Agriculture, one of the most common ingredients that enter into the composition of soils. Indeed, it may be asserted that no soil whatever will maintain its fertility for any length of time without a due proportion of clay in its composition. The most fertile soils in the world are the alluvial deposits on the

CLAY IRONSTONE

banks of rivers; and these, in an agricultural sense, all belong to clayey soil. In many cases the clays of agriculture are intimately united with calcareous earths, and in others with sand; but in both cases these earths are in a state of such minute division, that the mixture has all the appearance and the mechanical properties of a strong clay, and they are treated by cultivators accordingly. Among the most tenacious clays of Britain are those of Middlesex; and these, when examined, are found in many cases to contain a considerable proportion of lime, and in others of sand. The best wheats are everywhere, both in Britain and on the Continent, grown on calcareous clays; and also the best fruits and flowers of the Rosaceous kind, such as apples, pears, plums, cherries, roses, &c.; but it is remarkable that the grape, when grown on clayey soil, produces neither high-flavoured fruit nor good wine.

Clay Ironstone. The name commonly given to the compact kinds of Siderite or carbonate of iron, which are rendered impure by an admixture of clay. These occur chiefly as flattened spheroidal masses of various sizes, in many clay formations, more especially amongst those of the coal measures, and furnish the greater part of the iron which is produced in this country. The colour of this ore is generally yellowish-brown or reddish-grey, the fracture is finely granular, it is easily scratched, and gives out an argillaceous odour when breathed on. [BLACK BAND.]

Clay-slate. [SLATE.]

Clayey Soil. Soil in which clay is the principal earthy ingredient. Soils of this description when first subjected to cultivation are expensive to work and uncertain in their produce; but after they have been drained, cultivated, limed, and manured, they become the most fertile of all soils, producing immense crops of wheat, beans, clover, rye-grass, &c. Great improvement is also effected in them by partially burning them.

Clayite. A variety of Galena, containing about 25 per cent. of arsenic, copper, and antimony. It is found in Peru, in small blackish-grey crystals, with a metallic lustre; and as an amorphous coating upon Quartz. Named after the Hon. J. R. Clay, United States Minister in Peru.

Clerestory or Clerestory. The upper range of openings in Gothic churches or buildings, interposed between the roof of the centre aisle and the roof of the side aisles.

Cleats. On Shipboard, are pieces of strong

wood, shaped somewhat like two anvils joined at their thick ends, round which ropes are wound. The cleat is fastened to the ship's side or other part by a pin through the centre. Some cleats, however, have but one arm.

Cleavage. In Geology, a term applied to rocks capable of being split into parallel plates;

CLEPSYDRA

indefinitely thin. The property of cleavage, in the strict sense of the word, is confined to argillaceous rocks, and of all these the slates show the most perfect specimens.

Mechanical compression appears to produce on substances exposed to it conditions so like those of cleavage, that it is hardly possible to resist the conclusion that to this cause chiefly the phenomenon is due.

Cleavelandite. A mineralogical synonym for Albite; named after Parker Cleaveland, of Bowdoin College, United States.

Cledge. A miner's term, applied to thin strata of clay or fuller's earth.

Clef (Fr.). In Music, a mark prefixed to a staff, showing the tone or key in which a piece of music is written; it is a letter or other sign marked on a line, which determines the name of all those of the degree whereon it is placed. A clef is always placed on a line, never on a space. [Music.]

Cleft-grafting. A mode of grafting, in which the scion is inserted into a cleft made in the stock. [GRAFTING.]

Clepsydra (Gr. κλεψύδρα, from κλέπτω, *I steal*, and δῆμα, *water*). Water-clock; an ancient instrument for measuring time by the gradual emptying of a large vessel of water through an orifice of a determinate magnitude. Clepsydras were first brought into use in Egypt under the reign of the Ptolemies, and seem to have been common in Rome, though they were employed chiefly in winter; in summer sun-dials were used. Though clepsydras are attended with several inconveniences, the principal of which is the unequal rapidity of the flow caused either by a variation in the depth of the water in the containing vessel, or of temperature, or barometric pressure, they are nevertheless susceptible of considerable accuracy; and before the invention of clocks and watches, astronomers could depend only on clepsydras for measuring small portions of time. At present they are abandoned, because pendulum clocks and watches are much more convenient, as well as infinitely more exact. In one case, however, it has been proposed to revive their use; namely, for the accurate measurement of very short intervals of time by the flowing of mercury from a small orifice in the bottom of a vessel kept constantly filled to a fixed height. The stream is intercepted at the moment of noting any event, and diverted aside into a receiver, into which it continues to run till the moment of noting any other event, when the intercepting cause is suddenly removed. The stream then flows in its original course, and ceases to run into the receiver. The weight of mercury received, compared with the weight of that which passes through the orifice in a given time, observed by the clock, gives the interval between the events. This ingenious application of the principle of the clepsydra is due to the late Captain Kater.

A form of water-clock has also recently been devised by the Astronomer-Royal for commu-

nicating the necessary motion to telescopes equatorially mounted.

Clergy (Fr. *clergé*). The ecclesiastical body as distinguished from the laity.

Clerk (Gr. *κληρικός*, Lat. *clericus*). The legal appellation of a clergyman. The clergy being exclusively the learned part of the community in the middle ages, the word hence came to signify an educated person; and thus acquired the sense of a scribe or writer in France and England.

Clew. In Naval language, is the lower corner of a square-sail.

Clew-garnets. Are the same as clew-lines; but the term is only applied in connection with the courses or lower sails.

Clew-lines. Are small ropes used to draw the sail up to the yard when the sail is *clewed up* in the act of shortening sail.

Clichy White. A pure carbonate of lead, or white-lead, manufactured at Clichy in France.

Clients (Lat. *clieni*, from the old word *cluo*, *I hear or obey*). In Ancient History, a numerous body of the Roman citizens, so termed relatively to their patrons or protectors. This relation was in many respects similar to that of a serf to his feudal lord, but bore a much milder form. It was the duty of the patron to watch over the interests of his clients and protect them from aggression, and appear for them in lawsuits. He also frequently made them grants of land on lease. In return, the client was bound to defend his patron, and contribute towards any extraordinary expenses he might be subject to; as the portioning his daughters, the payment of a fine imposed by the state, &c. He might not appear as accuser or witness against him in judicial proceedings, a prohibition which was reciprocal. The body of clients was increased by the institution by which foreigners, who, as allies of Rome, had a share in its franchise, might choose themselves patrons on their coming to settle in the city. The obligations of clients were hereditary, and could not be shaken off unless through the decay of the family of the patron. The clients have by some been distinguished from the plebeians; by others they have been regarded as plebeians who of their own will entered into certain relations with the patrician families. (Ihne, *Researches into the History of the Roman Constitution*.)

It has been seen that among the other duties of a Roman patron towards his client was that of maintaining his cause gratuitously in legal proceedings. Hence the term *client* has become appropriated in modern times to one whose cause is prosecuted or defended and his person represented by an advocate. The custom of practising gratuitously as advocates long prevailed among the Roman patricians; and from it the usage was derived, which still obtains among ourselves, of considering the fee of a counsel as 'quiddam honorarium,' a gratuity which cannot be legally claimed. At present, the etiquette of the English bar appears to be

this: that a barrister cannot refuse, without strong grounds for such refusal, to undertake any cause which is offered him: that he cannot refuse, without reasonable excuse, to plead gratuitously the cause of a client who sues regularly 'in forma pauperis'; or to defend a prisoner if called on to do so by the court; and that he can receive no instructions with a fee except through the medium of a regularly authorised agent of his client (attorney or solicitor). An application to a barrister with the customary fee, to undertake a cause in which he is not yet instructed, is called a 'retainer,' and secures his services for the client. An application to undertake all causes for a particular client is a *general retainer*.

Climacterical Year (Gr. *κλιμακτηρικὸς*, from *κλιμακτήρ*, *the step of a staircase*). Certain years in the life of man have been from great antiquity supposed to have a peculiar importance, and to be liable to singular vicissitudes in his health and fortunes. This superstitious belief is said to have originated in the doctrines of Pythagoras. The well-known notice of the climacterical year sixty-three, supposed to be particularly dangerous to old men, in a letter of Augustus Cæsar preserved by Aulus Gellius, evinces its prevalence among the Romans. This year has been called by some astrological writers 'heroicus,' as having been peculiarly fatal to great men. The virtue of this year seems to consist in its being a multiple of the two mystical numbers, seven and nine. It is certainly singular that usage should have attached in all countries peculiar distinctions to those years which are denoted by compounds of the number seven. Thus fourteen has been fixed for various purposes as the epoch of puberty, twenty-one of full age; thirty-five is selected by Aristotle as the period when the body is in its highest physical vigour. The same author supposes the vigour of the mind to be perfected at forty-nine: sixty-three to be the grand climacterical year; seventy the limit of the ordinary age of man. Bodinus says that seven is the climacterical number in men and six in women. The term *climacteric disease* has more lately been applied to that declension of bodily and vital powers which is frequently observed to come on in the latter period of life, and from which many persons again rally so as to attain extreme old age.

Climate (Gr. *κλίμα*, from *κλίνω*, *I incline*). Among the ancient geographers, was applied to denote that obliquity of the sphere with respect to the horizon which gives rise to the inequality of day and night. They divided the space comprehended between the equator and the pole into thirty parts, which they denominated *Climates* or *Inclinations*; viz. twenty-four between the equator and polar circle, and six between the polar circle and the pole. The first are called *half-hour climates*, because from one to another the longest day receives an augmentation of half an hour; the second are called *month climates*, because at the two parallels between which any one of them is

CLIMATE

comprehended the difference of the time of perpetual sunshine is one month. The first half-hour climate reaches from the equator to that parallel of latitude where the length of the longest day is twelve hours and a half; the second ends at the parallel where the longest day is thirteen hours, and so on. If, therefore, from the number of hours in the longest day at any particular place we subtract twelve, the number of half-hours remaining will indicate the climate in which that place is situated. Thus, the longest day at London being a little more than sixteen hours and a half, London is situated in the tenth climate.

Climate, in its most ordinary and general acceptation, embraces all those modifications of the atmosphere by which our organs are sensibly affected: such as temperature, humidity, variations of barometric pressure, the tranquillity of the atmosphere or the effects of winds, the purity of the air or its mixture with gaseous emanations more or less salubrious and lastly, the habitual diaphaneity of the atmosphere—that serenity of the sky so important on account of the influence which it exercises not only on the development of organic tissues in vegetables and the ripening of fruits, but also on the *ensemble* of moral sensations which mankind experience in the different zones. There are two general causes on which the climate peculiar to any country principally depends—1st. Its distance from the equator; and 2nd. Its altitude above the level of the sea; but their effect is generally modified by many circumstances exerting a partial influence. Among these may be enumerated the configuration and extent of the country; its inclination and local exposure; the direction of the chains of mountains by which it is intersected, or which are in its vicinity; the nature of the soil as it is more or less favourable to radiation, absorption, and evaporation; the proximity to, or distance from, seas; the action of winds blending the temperatures of different latitudes; and even the changes produced by cultivation. The appreciation of all these causes, which modify the results deduced from the consideration of latitude and elevation alone, and the effect produced by their combined operation, constitutes the science of *climatology*.

Effect of Geographical Position.—Other things being equal, the temperature enjoyed by any country depends on the heat which it receives directly from the sun. In estimating the amount of solar heat received by any given space on the surface of the earth in the course of a whole year, we may suppose the sun to remain constantly in the equator, because the excess of heat above the mean in summer is exactly balanced by its defect in winter. Now, the effect produced on any given portion of the surface will depend on the number of rays that fall on that surface, and on the obliquity of their direction with respect to it. But the number of rays falling on a zone of any given breadth, a degree for example, is proportional

to the cosine of its latitude; and the effect of a single ray in consequence of its oblique impact is diminished also in proportion to the cosine of the latitude; the diminution of the mean temperature, therefore, in going from the equator to the poles, must be proportional to the square of the cosine of the latitude. It hence follows that the variations of the mean temperature must be most rapid about the middle latitude of 45° ; and this result of theory agrees perfectly with observation. Within the temperate zone the character of the climate changes rapidly. Thus, in the South of France, and in Italy, nearly under the 45th parallel, the region of the vine is found contiguous to that of the olive and fig-tree. On the other hand, very little increase of heat is observed from the tropic to the equator; and at the other extremity of the arc, from the arctic circle to the highest latitude that has been reached, the intensity of cold is not greatly augmented. The law of the square of the cosine gives a variation of only about eight degrees of Fahrenheit's scale from the polar circle to the pole. In the system of climates of Western Europe, the mean temperature at the latitude of 45° is about 13° or 13.5° of the centigrade scale (55° to 56° of Fahrenheit). The mean temperature under the equator ought therefore to be, by the theory, 26° or 27° (centigrade); and at any other place it will be found by multiplying the constant number 27 into the square of the cosine of the latitude.

Effect of Altitude.—That a greater degree of cold prevails in the upper regions of the atmosphere than at low levels would be manifest by the snowy covering of the summits of very elevated mountains in all latitudes, even if no direct experiments had been made on the temperature that prevails there. These, however, have been made in great number; and the constant and regular decrease of the temperature in ascending above the surface of the earth, to such altitude at least as can be reached, has not only been fully established, but the law according to which the decrease takes place determined with considerable certainty. According to theory the decrements of heat in ascending the higher regions should follow the same proportion as the decrements of the density; but this law is greatly disturbed by local peculiarities. The variation of temperature at different altitudes is caused in the following manner: the rays of *luminous* heat from the sun pass through a clear atmosphere, with but little loss from absorption; they therefore exercise but little heating effect upon the air. When these rays strike the earth, they are absorbed, and the surface, be it land or water, becomes heated, and begins to emit rays of *obscure* heat. The latter pass easily through absolutely dry air, but are arrested, as Professor Tyndall has shown, by the aqueous vapour which is almost invariably present in the lower strata of the atmosphere. Hence these rays of obscure heat are intercepted chiefly by the air near the surface of the earth, which therefore be-

CLIMATE

comes warmer than the superincumbent strata. But this warmer air ascends, and might therefore be expected to mix with the colder air above, and thus produce an approximately uniform temperature; but the ascent of the warm air involves the performance of mechanical work, which necessitates the disappearance of heat. Thus the air becomes colder as it ascends, and if it start from the surface of the earth with a temperature of 80° Fahr. it may be cooled to the freezing point of water by the time it has reached a height of 15,000 feet. In the torrid zone, Humboldt, from a mean of many observations, found that between the altitudes of 3,000 and 5,800 metres (9,840 and 19,000 feet) an increase of elevation, amounting to 191.4 metres, produced a diminution of 1° of the centigrade thermometer. This corresponds to 349 English feet for 1° Fahr. Professor Leslie (*Ency. Brit.* art. 'Climate') estimates that the diminution of temperature of 1° of Fahrenheit's scale corresponds to an ascent of 300 feet. But this will hold true only of moderate elevations. At the altitudes of 1 mile, 2 miles, 3 miles, 4 miles, and 5 miles, the increase of elevation corresponding to 1° Fahr. will be respectively 295, 277, 252, 223, and 192 feet. The allowance of 1° of Fahr. for every 100 yards of ascent is, however, a rule of easy recollection, and in ordinary cases may be taken as a sufficient approximation.

Effect of large masses of Water and of general Configuration.—The form of the boundaries of any large mass of land as determined by its contact with the ocean, that is to say, the greater or less extent of coast it possesses in proportion to its area, exercises a considerable influence on the climate. The small amount of variation in the temperature of the ocean tends to equalise the periodic distribution of heat among the different seasons of the year, and the proximity of a great mass of water moderates by its action on the winds the heat of summer and the cold of winter. Hence the great contrast between the climate of islands and coasts, and the climate of the interior of vast continents. Europe presents a remarkable example of this contrast. From Orleans and Paris to London, Dublin, Edinburgh, and even further north, the mean temperature of the year decreases very little, notwithstanding the increase of latitude; while in the eastern part of the Continent each degree of latitude, according to Humboldt, produces a variation of 1.1° Fahr. in the mean temperature. A small island, a tongue of land, or an indented coast, in contact with a great mass of water, which preserves in winter a considerable portion of the heat acquired during the summer, possesses a more moderate climate, milder winters, and fresher summers, and in the higher latitudes a somewhat higher mean temperature, than the interior of great continuous masses of land under the same latitude. The diminution of the mean annual temperature from the western shores of Europe to beyond the meridian of the Caspian is remarkable. Amsterdam and Warsaw are situated very

nearly under the same parallel of latitude, that of the first being $52^{\circ} 22'$, and that of the second $52^{\circ} 14'$; but the mean annual temperature of Amsterdam is 53.4° Fahr., while that of Warsaw is only 46.48° . The latitude of Copenhagen is $55^{\circ} 41'$, and that of Kasan $56^{\circ} 48'$; but the mean annual temperature of Copenhagen is 45.7° , that of Kasan 37.6° .

Proximity to large masses of water also involves the presence of much aqueous vapour in the atmosphere. Speaking of the influence of this aqueous vapour on climate, Professor Tyndall says:—

'Aqueous vapour is a blanket more necessary to the vegetable life of England than clothing is to man. Remove for a single summer night the aqueous vapour from the air which overspreads this country, and you would assuredly destroy every plant capable of being destroyed by a freezing temperature. The warmth of our fields and gardens would pour itself unrequited into space, and the sun would rise upon an island held fast in the iron grip of frost. The aqueous vapour constitutes a local dam, by which the temperature at the earth's surface is deepened: the dam, however, finally overflows, and we give to space all that we receive from the sun.

'The sun raises the vapours of the equatorial ocean; they rise, but for a time a vapour screen spreads above and around them. But the higher they rise, the more they come into the presence of pure space, and when, by their levity, they have penetrated the vapour screen, which lies close to the earth's surface, what must occur?

'It has been said that, compared atom for atom, the absorption of an atom of aqueous vapour is 16,000 times that of air. Now the power to absorb and the power to radiate are perfectly reciprocal and proportional. The atom of aqueous vapour will therefore radiate with 16,000 times the energy of an atom of air. Imagine, then, this powerful radiant in the presence of space, and with no screen above it to check its radiation. Into space it pours its heat, chills itself, condenses, and the tropical torrents are the consequence. The expansion of the air, no doubt, also refrigerates it; but in accounting for those deluges, the chilling of the vapour by its own radiation must play a most important part. The rain quits the ocean as vapour; it returns to it as water. How are the vast stores of heat set free by the change from the vaporous to the liquid condition disposed of? Doubtless in great part they are wasted by radiation into space. Similar remarks apply to the cumuli of our latitudes. The warmed air, charged with vapour, rises in columns, so as to penetrate the vapour screen which hugs the earth; in the presence of space, the head of each pillar wastes its heat by radiation, condenses to a cumulus, which constitutes the visible capital of an invisible column of saturated air.

'Numberless other climatal phenomena receive their solution by reference to the radiant and absorbent properties of aqueous vapour.

It is the absence of this screen, and the consequent copious waste of heat, that causes mountains to be so much chilled when the sun is withdrawn. Its absence in Central Asia renders the winter there almost unendurable; in Sahara the dryness of the air is sometimes such, that though during the day 'the soil is fire and the wind is flame,' the chill at night is painful to bear. In Australia, also, the thermometric range is enormous on account of the absence of this qualifying agent. A clear day and a dry day, moreover, are very different things. The atmosphere may possess great visual clearness, while it is charged with aqueous vapour, and on such occasions great chilling cannot occur by terrestrial radiation. Sir John Leslie and others have been perplexed by the varying indications of their instruments on days equally bright; but all these anomalies are completely accounted for by reference to this newly-discovered property of transparent aqueous vapour. Its presence would check the earth's loss; its absence, without sensibly altering the transparency of the air, would open wide a door for the escape of the earth's heat into infinitude.' (*Royal Institution Discourse*, Jan. 23, 1860.)

The climate of a country is influenced not only by its horizontal configuration, but also by its *relief*, or vertical configuration. Mountains affect the climate of the adjacent plains in various ways—by the reverberation of heat from naked rocks; by affording shelter from certain predominating winds; and by giving rise to descending currents of cold air from the higher regions of the atmosphere, in consequence of the disturbance of the equilibrium of heat produced by the radiation from their sides and summits. The local exposure of a country also, or its inclination to or from the equator, which may be included under the title *configuration*, has a powerful influence on its mean annual temperature. Generally speaking, the local exposure is connected with and depends upon the position of the mountain chains, and both conspire to increase or diminish the mean temperature at the same time. For example, when the general inclination of an extensive tract of country in the northern hemisphere is towards the south, the northern side is bounded by ranges of mountains; so that while the sun's rays fall upon it at a less oblique angle, it is sheltered from the cold winds blowing from a higher latitude.

Climate of Europe.—In a general view, Europe may be regarded as a peninsular prolongation of the ancient continent, broken and intersected by numerous arms of the ocean, and by inland seas. The predominating winds are from the west; and these, for the whole of the western portion, are sea winds, greatly softened by blowing over a mass of water, of which the superficial temperature, even in the month of January, at the parallels of 46° and 50°, does not fall below 48° and 51° of Fahrenheit. It is placed directly north of an immense tract of tropical land (Africa and Arabia), which by

its diurnal radiation contributes powerfully to elevate the temperature. On the northern side the cold belonging to the latitude is mitigated by numerous favourable circumstances. A very small portion of land lies within the polar circle; and the whole of the northern extremity is separated from the polar ice by a zone of open sea, the temperature of which is maintained at a considerable elevation in consequence of its communication with the Atlantic Ocean, and of the existence of the Gulf Stream, which conveys a portion of the warmth of the gulf of Mexico into the polar seas, and to the western shores of the British Islands.

Climax (Gr. *a ladder*). In Rhetoric, a figure by which several propositions, or several objects, are placed before the mind of the hearer or reader in such an order that the proposition or object calculated to produce the least impression shall strike it first, and that the rest shall follow in regular gradation. *Anti-climax* is the converse figure, in which the ideas sink in succession. This forms a principal cause of that vice of composition of which so many ludicrous illustrations have been given under the name of *bathos*.

Climanthium (Gr. *κλίση, a bed, and άνθος, a flower*). In Botany, a term used to express the receptacle of a Composite plant. It is the dilated apex of a flowering branch covered over by small flowers enclosed within an involucre.

Clinical (Gr. *κλινικός, belonging to a bed*). This term is generally used medically; a *clinical lecture*, for instance, is the instruction which the teacher gives his pupil at the bedside of the patient.

Clinium (Gr. *κλίση*). A term occasionally used in Botany to denote the summit of a floral branch, of which the carpels are the termination. It is the same as the *torus* of the modern French school, and one of the parts called *receptacle* by Linnæus, as in the strawberry.

Clinkers. [BRICKS.]

Clinoclase (Gr. *κλίω, to incline, and χλωρός, green*). A hydrated silicate of alumina, iron, magnesia, &c., found in crystals and plates of an olive-green colour, with a micaceous structure and pearly lustre, at Leugast in Bavaria, Achmatowsk in the Ural, and in Pennsylvania.

Clinoid (Gr. *κλίση, and είδος, likeness*). This term has been improperly applied to certain processes of the *sphenoid bone*.

Clinometer (a word coined from Gr. *κλίση, and μέτρον, a measure*). An instrument constructed to enable a geological observer to determine the dip of beds.

Clintonite. A hydrated silicate of alumina, magnesia, lime, soda, peroxide of iron, &c., found at Amity in New York, and named after Mr. De Witt Clinton. [BRANDISTE.]

Clio or **Clete.** In Greek Mythology. One of the nine Muses. (Hesiod. *Theogony*, 50-104.) In later times she was looked upon as the Muse of History.

CLIO. In Zoology, applied by Linnæus to a genus of *Vermes*, and by Cuvier to a genus of Pteropodous Molluscs; one species of which, the *Clio borealis*, abounds in the northern seas, and although not exceeding an inch in length, forms a great proportion of the food of the whalebone whale, *Balæna Mysticetus*.

Clipper (a word probably introduced in America, from the verb to *clip*, in the sense of to divide or cleave). A cargo ship, especially constructed for speed. They were built in the first instance for the conveyance of perishable goods, and the fruit-clippers and slave-clippers became known as the fastest vessels afloat. Of late years the finest clippers are those of Liverpool and American build, which are employed in the Atlantic and Australian traffic. Clippers are usually of a sharp form, with finely curved bows and generally an elliptical shape, having a deep keel and lofty masts. Some of the finest of these vessels have made the voyage to Australia as rapidly as the mail steamers.

Cloaca (Lat.). The excrementory cavity in which, in birds, reptiles, many fishes, and some mammals, the intestinal canal, urinary ducts, and genital passages terminate.

Clock. [HOROLOGY.]

Cloister (Ger. kloster, Lat. claustrum, from claudo, *I shut*). In Architecture, this term is usually applied to the covered walk, ambulatory, or passage from one principal part of a conventual building to another; or, in fact, a colonnade round an open court.

Close-burning Coal. The term *close-burning* is applied to those strong-burning, blazing descriptions of bituminous coal which, from their tendency to swell in the fire and form a more or less coherent pasty mass, prevent a free draught of air in the furnace, and have to be coked before they are used. [CAKING COAL AND OPEN-BURNING COAL.]

Close-hauled. In Navigation, the tacks close down, the sheets aft, the yards braced sharp up, and the bowlines hauled, the ship making her progress as near the direction of the wind as she can.

Closers. In Architecture, the pieces (or batts) less or greater than half a brick that are used to close in the end of a course of brickwork. In Flemish bond [Bond] the length of a brick being but nine inches, and its width four inches and a half, a quarter brick (or batt) must be interposed to preserve the continuity of the bond; this is called a *queen closer*. A similar preservation of the bond may be obtained by inserting a three-quarter batt at the angle in the stretching course; this is called a *king closer*. In both cases a horizontal lap of two inches and a half is left for the next header. The term is also applied to mason's work, and it signifies in that case the piece of stone introduced to fill up a course of ashlaring around a building in such a manner as to secure the breaking of the vertical bond.

Cloud. A visible mass or collection of minute particles of water suspended in the

atmosphere. Clouds differ from fogs or mists only in occupying a more elevated position; in all cases the origin is the same, namely, the vapours which rise from collections of water, and indeed from the whole surface of the earth. These aqueous vapours are condensed in the higher and colder regions of the atmosphere, and thus lose their transparency and become visible. Clouds differ very greatly in respect of form, magnitude, density, &c. These differences depend on the quantity of vapour of which they are composed, and the situations which they take as they unite with one another; and are determined in a great measure by the direction and velocity of the motion communicated to them by the wind. The height at which they float in the atmosphere is determined by their specific gravity, and consequently varies with their density. Thin light clouds are observed higher than the summits of the loftiest mountains, while those which are dense and thick rise only to a small distance above the surface of the earth. It is very difficult to determine their average elevation: it is supposed to be between two and three miles, but it varies at different times of the year.

Clouds were distributed by Mr. Luke Howard into three primary formations—the *Cirrus*, the *Cumulus*, and the *Stratus*. But besides these he admitted four other varieties—the *Cirro-cumulus*, the *Cirro-stratus*, the *Cumulo-stratus*, and the *Cumulo-cirrostratus* or *Nimbus*. The *Cirrus* consists of fibres or curling streaks, which diverge in all directions. It occupies the highest region, and is frequently the first cloud which is seen after a continuance of clear weather. The *Cumulus* is a convex aggregate of watery particles, increasing upwards from a horizontal base, and assuming more or less of a conical figure. The *Stratus* consists of horizontal layers, and comprehends fogs and mists. It is the lowest of the clouds, its under surface usually resting on the earth or water. The *Cirro-cumulus* is intermediate between the cirrus and cumulus, and is composed of small well-defined masses closely arranged. The *Cirro-stratus*, intermediate between the cirrus and stratus, consists of horizontal masses separated into groups, with which the sky is sometimes so mottled as to suggest the idea of resemblance to the back of the mackerel. The prevalence of the cirro-stratus is usually followed by bad weather. The *Cumulo-stratus*, or *twain cloud*, partakes of the appearance of the cumulus and stratus or cirro-stratus. The *Nimbus*, or *rain cloud*, is that into which the others resolve themselves when rain falls.

The above nomenclature is sufficiently fanciful; nevertheless it enables the meteorologist to convey more precise ideas in describing the diversified forms under which masses of clouds present themselves, and their connection with the changes of the weather. These forms are, however, frequently so ind. finite and shapeless, that it is difficult, if not impossible, to refer them to any one of the preceding modifications.

CLOUTED CREAM

A tendency, however, to one or other of them may in general be traced. (Howard's *Arrangement and Nomenclature of Clouds*, in the 16th and 17th vols. of the *Philosophical Magazine*; Foster *On Atmospheric Phenomena*; Murray's *Encyclopedia of Geography*, p. 168; *Companion to the British Almanac* for 1830, &c. See also Dalton's *Meteorological Essays*, 1793.)

Clouted or Clotted Cream. The cream produced, in Somersetshire and Devonshire, by setting a pan of new milk on a hot hearth.

Cloves. The unexpanded flower-buds of the *Caryophyllus aromaticus*, a low branching myrtaceous tree cultivated in the Dutch settlements in India. The finest cloves are from Amboyna; they are of a bright brown colour, extremely fragrant, and hot and acrid upon the tongue; they abound in essential oil, which may be pressed out of their pores by the nail, and which is generally obtained by distillation with water, to the amount of from fifteen to twenty per cent. It is sold in commerce under the name of *oil of cloves*, and is chiefly used in medicine, and occasionally in perfumery. The fruit of the clove-tree was employed in old pharmacy under the name of *anthophylli*.

Cloves. In Botany, the smaller bulbs formed in the axillæ of the scales of a mother bulb, as in garlic.

Club Moss. A name applied to *Lycopodiums*. The seeds of one species, *L. clavatum*, which are very minute, and resemble an impalpable yellow powder, are used in theatres to imitate lightning; when thrown across a flame, they produce a sudden flare. They contain a peculiar oil.

Club-hauling. In Navigation, a critical mode of tacking, resorted to only in perilous situations, when a ship has no other escape from running ashore. It consists in letting go the lee-anchor as soon as the wind is out of the sails, thereby bringing the ship's head to

She will then pay off, when the cable

By this
in a far

ter distance than it could otherwise be.

Clubbing. A hypertrophy of the roots of plants, chiefly of the cabbage and other *Brassicæ*, in which the root becomes roughly swollen and marbled like a truffe. On some ground, chiefly that which is exhausted by long cultivation, cabbages are very liable to suffer in this way, the growth of the stem being arrested. The best remedy is wood ashes dropped in the hole when the plant is put in.

Clump. The compressed clay of coal strata.

Clunch. In Geology, the hard and often dirty-looking bed of the lower chalk. When not exposed to weather, this material is well adapted for decorative purposes in architecture. Many of our cathedrals show good specimens that have retained their sharp edges for centuries. In the clunch the silicious particles that were removed to form beds of flint in the white upper chalk are generally found disseminated among the chalk itself, giving it a greyer colour and harsher feel. It rests on

COADJUTOR

the upper greensand (an arenaceous bed), and often contains clay.

Clunians. In Ecclesiastical History. An order of monks, so called from the abbey of Clugny, on the Saône, founded by St. Bernard early in the tenth century. There were many houses of this order in England before the dissolution of monasteries. (Hook's *Church Dictionary*; Milman's *Latin Christianity*, bk. viii. ch. iv.)

Clusia (after De l'Écluse, an eminent French botanist). A genus of *Guttiferae*, or *Clusiaceæ* as it is sometimes called, chiefly distinguished by its capsular five or ten celled fruit, and by the numerous stamens which open by their whole length. They are tropical trees, and one of them, *C. Galactodendron*, a native of Venezuela, is one of the Cow-trees (Palo de Vaca) of South America. The milk flows from incisions made through the bark to the wood, one tree yielding about a quart in an hour.

Clutches or Glands. In Machinery, couplings which have no coupling boxes are denominated *clutches* or *glands*. A coupling of this kind consists of two crosses, one fixed to the end of each of the shafts to be connected. One of the crosses, having its end bent forward, lays hold of, or *clutches*, the other, and by doing so turns round the other shaft. Instead of cross pieces two round cast-iron plates are sometimes used, each having a part cut out, and a corresponding projection. The projection of the one plate is inserted in the opening of the other, and thus serves to engage the shafts. (Buchanan *On Mill Work*.)

Clypeaster (Lat. clypeus, a buckler, and astrum, a star). A genus of sea-urchins (*Echinida*) of a flattened shield-like form, with a submarginal vent. This genus is termed *Echinanthus* by Klein.

Clypeate (Lat. clypeatus, from clypeus). Shield-like, or scutate.

Clyssus. An alchemical name for the water obtained by deflagrating nitre with charcoal: the vessels were generally burst in the operation; but when it succeeded, the few drops of water obtained were highly prized for medical use.

Coacervate (Lat. coacervatus, part. of coacervo, *I heap together*). Accumulated. A term applied by older physiologists to certain secretions or excretions long retained.

Coadjutor (Lat. co, and adjutor, a helper). In Ecclesiastical matters, the assistant of a bishop or other prelate (in some instances even of a canon or prebendary, but the latter usage was irregular). A coadjutor was equal in rank to the dignitary whose functions he might on occasion supply; hence the coadjutor of a bishop was himself consecrated a bishop *in partibus infidelium*. The celebrated cardinal de Retz was known by the title of the Coadjutor of Paris during the most active period of his career, having the administration of the temporalities of that see, which belonged to his uncle the archbishop de Retz. Coadjutors usually succeeded their principals in their

dignities; and hence arose an abuse which tended to make ecclesiastical dignities hereditary, nephews and other relatives of bishops being named their coadjutors. The institution of coadjutors to bishoprics is preserved by the French concordat of 1801.

Coadunate (Lat. *coadunatus*, part. of *coaduno, I unite*). In Botany, two or more parts joined together.

Coagulable Lymph. A term given in some surgical works to the fibrine of the blood, which is the only part that has the power of spontaneously coagulating.

Coagulum (Lat.). The part of the blood which changes from the fluid to the solid state, when drawn from the body and left at rest, or subjected to heat or certain chemical reagents. It consists of the fibrine with the blood-discs.

Coal (Ger. *kohle*). This remarkable and well-known mineral consists essentially of carbon combined with certain gases and mixed with certain earthy impurities, which affect its value for practical purposes and sometimes alter its appearance.

The essential characters of coal in Practical Geology are derived from its colour, texture composition, and uses as a combustible. The associated rocks are not unimportant; and the thickness and number of the coal seams within certain limits greatly affect the value of a deposit.

Coal differs from most rocks very distinctly. Some black minerals, such as obsidian, black quartz, and others, resemble it, but are distinguishable in a moment by texture, and also by their being non-combustible. There is, however, a rock into which it passes by gradations which are often hardly

[**BITUMINOUS SHALE.**] Generally alternating with shale or hard clayey bands, these have not unfrequently obtained from the coal so much carbon and of various hydrocarbons as to be quite black, and even to burn with facility, though with a large percentage of ash. It is sometimes not easy to determine to which of the two rocks a given specimen belongs.

Of coals there are many kinds. **ANTHRACITE** is the richest in carbon; **STEAM COAL** contains sufficient gas to burn with flame, and get up steam economically, but is not rich in gas; the ordinary *bituminous caking coals* are sufficiently rich in gases to be useful for destructive distillation if required, but equally useful for house fires and all the ordinary purposes of fuel; the **CANNEL COALS** are so rich in gas as to be uneconomical except for the manufacture of gas; and the very richly bituminous coals of Scotland, the minerals called **Boghead Coal**, **Torrane-hill Mineral**, **Liswahago Coal**, and some others, approach so nearly in all respects to the condition of bituminous shales that they are far more valuable for slow distillation to procure oils and paraffine, than directly as fuel or for destructive distillation to make coke and gas.

Coal is very widely distributed over the earth. It is found in all the principal divisions of the

globe, and is of all geological ages. Whatever its origin may have been, it is certainly a mineral that has been in course of formation since the existing state of the world began. It probably is so still. Silurian coals have not indeed yet been found, though strong indications exist of large deposits of carbon of that period. Devonian coal is abundant. The carboniferous series is that which yields the chief supplies in Western Europe and Eastern North America. Permian coal is probable. Liassic coal abounds, and the whole of the oolitic series seems to contain carbonaceous deposits, as we advance towards the East. Cretaceous coal occurs at intervals in Hungary and the East, not indeed so good as could be desired, but still true coal, and excellent beds of true coal of the older tertiary period are found in mountain valleys of the Carpathians. Besides these are the enormous deposits of lignite or brown coal, widely spread in various parts of the world, but generally of tertiary date.

Coal is usually interstratified with clayey beds converted into shale and with sandy beds converted into sandstone or grit, and both of these usually show vegetable impressions, proving the near vicinity of land at the time of the deposit. The structure of coal itself also shows here and there distinct proof of vegetable origin; but whether in all cases the coal is an accumulation of decomposed and altered leaves and trees, or whether it has been so far altered before being deposited as to have lost most part of its structure, has not been clearly determined. Certainly the indications of vegetable tissue and cell-structure are not universal, though common, in prepared specimens examined under the microscope. Thus the true origin of the great deposits of coal remains obscure, though indirectly there can be no doubt that vegetation is the material that they were derived from.

But the changes involved in passing from the ordinary state of vegetable matter to the condition of coal are neither few, small, nor easily comprehended. The whole of the carbon remains, but other substances by no means unimportant, which help to form woody fibre, are generally absent. The best coal contains no water, no potash, no phosphorus, and very little silica, lime or iron, or if at any time it does contain such elements, the quantity is with the exception of silica, lime and iron) absolutely inappreciable by the best chemical tests, whereas the proportion of these in wood and leaves varies from 2 to nearly 12 per cent., and the water, potash, and phosphorus are essential ingredients. On the other hand, sulphur is not unfrequently present with iron in coal, and this element is only rarely found in certain succulent vegetables, and is then without iron. The change then from common vegetation to coal is complete, and involves an amount of decomposition little short of destruction.

The quantity of coal present in different coal fields is a matter of calculation; but it is clear

COAL BRASSES

that, however large it may be, the quantity of available coal is limited. The coal fields of England are neither the largest nor the best supplied; and being greatly broken by the disturbances which have brought them within reach, they are in places much injured. Owing, however, to the fact that they are well situated for working on a large scale and for exportation, they have been more steadily attacked and for a longer time than any others in the world. Upwards of eighty millions of tons are now removed annually from the earth in the British Islands, and some of the beds are beginning to show symptoms of exhaustion. Fortunately, however, new beds are from time to time discovered that were not before known or even suspected; and as the necessity for coal becomes greater, efforts are constantly being made, and with success, to discover new fields and enlarge the workable limits of old ones. In time, perhaps, some may be absolutely exhausted, but practically there seems to be an ample supply for all human requirements if only due care be observed in working.

Coal is of all minerals the most valuable, as it involves the employment of the largest amount of human labour, and leads to the most important results. By it we obtain heat and light for all the main purposes of life, and without it none of the modern contrivances for rapid locomotion would be available. Although by no means the only fuel, it is so convenient, so portable, so cheap, so readily transported without serious injury, and so abundant, that we could hardly carry on any of our most profitable manufactures in this country without it. The great coal-mining districts are almost without exception the seats of our industry in iron, clothing, glass, pottery, and other manufactures, for the sole reason that fuel is the most essential of all minerals, and that its price governs the cost of manufacture.

The most remarkable coal fields of Europe at present in actual work, after those of our own country, are the following: Belgium, France, Rhenish Prussia, Silesia, Bohemia, Spain, and Russia. Those of Spain and Portugal are the least developed. The Russian deposits are also not very actively handled. [ANTHRACITE; CANNEL COAL; STEAM COAL.]

Coal Brasses. A name given, in the Newcastle and some other coal-mining districts, to the Iron Pyrites which occurs mixed with the coal and shale, and from which it is picked by hand and used in the manufacture of sulphuric acid.

Coal-tar. A constant product of the destructive distillation of coal in gas-making. It consists of *light naphtha*, used as a source of Benzole, and as a solvent of india-rubber and gutta-percha; *heavy naphtha*, coal-oil, or *dead-oil*, used as a lubricating agent, as an antiseptic, and as a source of lamp black; and *pitch*, used in making black varnish. By rectification, coal-tar yields no less than fifty distinct chemical substances, among which are the following:—

COAST-GUARD

Bases	Neutral	Acids
Picoline.	Benzole.	Acetic.
Leucoline.	Tolnol.	Phenyllic.
Aniline.		Brunolic.
Pyridine.		Rosolic.

Three of them, viz. benzole, phenylic acid, and aniline, are remarkable as the sources of the celebrated coal-tar colours. Although these three substances differ very much in properties, yet in composition they stand in a very simple relation to each other. They all contain the same compound organic radical, phenyl. Benzole is the material from which nearly all the coal-tar colours are made. For the production of colour, however, benzole must be converted into aniline. This is effected by heating it, first with nitric acid, and then with acetic acid and scraps of iron. Mauve is produced by heating aniline with bichromate of potash and sulphuric acid. Magenta is obtained by heating aniline with arsenic acid. Blue and violet are prepared by heating magenta with aniline. 30 cwt. of coal yield 360 lbs. of tar, which furnish 18 lbs. of naphtha, containing 6 lbs. of benzole. 6 lbs. of benzole give 6 lbs. of aniline, which produce 1 lb. of magenta. 1 lb. of magenta will dye 650 lbs. of silk, or 900 lbs. of wool, the latter being the average produce of 160 sheep.

Coamings. On Shipboard, are raised borders around the hatches, intended to prevent water from running into the decks below.

Coarse Coal. A kind of black or bituminous coal, composed of granular concretions aggregated together. This description of coal, which is also called Splint Coal, is not common in Great Britain.

Coast Volunteers. A species of naval militia instituted in 1853. It comprises men employed in the coasting trade, and in vessels which make short voyages to and from home ports. The men have to train for twenty-eight days in the year under officers of the coast-guard. They receive an annual fee as a retainer, navy pay while training, and a pension after certain service. In return they are liable to be called on to serve in time of emergency in any of her majesty's ships for two years; and they are bound not to engage, without special permission, in any voyage which is likely to keep them more than six months out of the United Kingdom. The strength of the force in 1864 was 7,500 men, and the cost 38,918*l*.

Coast-guard. A semi-naval organisation of seamen, mostly living along the shores of the United Kingdom, intended originally for the prevention of smuggling; but since the removal of prohibitive import duties, and the consequent decrease of smuggling, converted into a force for the defence of the coasts. Great Britain and Ireland are divided into eleven districts, each under a captain in the navy, who has a blockship for his headquarters. Under him are numerous inspecting officers, each in charge of a sub-district, with probably

COAST-LINE

a revenue cruiser or gunboat attached. The men are old men-of-war's men of good character. They have free cottages along the shore and high sea-pay, with 1s. 4d. a day each instead of provisions. They are, however, liable to service afloat in the district guardships and cruisers at all times, and in time of war are liable for active service wherever required. The whole service is under a controller-general, having rank as a commodore of the first class. In 1864-5 the strength of the coastguard was 8,450 men, of whom 3,500 were employed afloat. The total cost was estimated at 721,697*l*.

Coast-line. Very important results follow from the degree to which a coast is indented by inlets, bays, gulfs, rivers, estuaries, or other natural interruptions of a straight line; and in proportion as the coast-line of an island or continent is longer as compared with the simplest possible line enclosing the same area, is there generally facility of access, shelter for ships, and a capacity for commerce. The coast of Europe is exceedingly remarkable in this respect as compared with any other part of the world; for with an area of 3,750,000 square miles, one side of which is in contact with Asia, there is a length of coast of nearly 20,000 miles; while Africa, with an area of twelve millions of square miles, has less than 15,000 miles of coast; and even Asia, whose area is 17,500,000 square miles, has only 30,000 miles. Of the Americas, again, the Atlantic and Pacific coasts are very different, for the former presents upwards of 23,000 miles, and the latter only 15,500 miles of coast-line. The most important trading countries are always those with the longest coast-line; and thus the British Islands bear almost the same ratio in this respect to Europe generally that Europe does to Africa.

Cob-walls. Walls formed of mud mixed with straw; not uncommon in some districts of England.

Cobalt (Ger. kobold, *a devil*). A term applied to this metal by the German miners, who considered it unfavourable to the presence of the more important metals.

Cobalt is a brittle metal of a reddish-grey colour; its specific gravity is 7·8. It fuses at a temperature a little below that required for the fusion of iron. It is magnetic. Its equivalent number is 30; and the salifiable, or protoxide of cobalt, consists of 30 cobalt + 8 oxygen = 38 oxide of cobalt. The oxide of cobalt is nearly black; but when in the state of hydrate, or when largely diluted by fusion with glass or borax, it produces its characteristic blue colour; and as this colour is permanent at very high temperatures, it is an invaluable article in the manufacture of porcelain and pottery, all the blue colours of which are derived from oxide of cobalt. When fused with glass it communicates a blue tint without impairing its transparency. A very deep blue glass of this kind, when finely powdered, acquires a pale and brilliant colour, and is called *smalt*. Impure

COCCINELLA

oxide of cobalt is known in commerce under the name of *saffre*. Cobalt is said by Stromeyer to exist in all meteoric iron, although in very small quantity. In its ores it is always associated with arsenic, and saffre is prepared by roasting these native arseniurets of cobalt.

Cobalt Glance or Cobaltine. A native sulpharsenide of cobalt, in which a part of the cobalt is often replaced by iron. It occurs crystallised and massive. This ore of cobalt furnishes a great part of the *Smalt* of commerce, which is employed in glass and porcelain painting and for giving a blue tint to paper and linen. It is now worked in Cornwall, but the most productive mines are those of Wehna in Sweden.

Cobbles. Lumps of coal from the size of an egg to that of a football.

Cobitis (Lat. cobio or gobius, Gr. *κοβίdis*). A genus of soft-finned fishes, belonging to the *Cyprinids* or carp family, and characterised by a small head; an elongated body; the skin covered with small scales; ventral fins placed far backwards, with one small dorsal fin above them; mouth small and toothless; gill openings very small, and with three rays. Of this genus the loche (*Cobitis barbatula*) inhabits the clear running streams of Britain. The pond loche (*Cobitis fossilis*) is a larger species. It is remarkably sensitive to atmospheric changes, and when confined in a glass globe may be observed to sink to the bottom in a state of quiescence when the weather is cold and gloomy; but in boisterous weather it comes to the surface and swims about with great rapidity. It also swallows air, which it discharges from the vent, partly converted into carbonic acid gas.

Coble. A small boat or canoe, used chiefly on the rivers and lakes of Wales and the borders.

Coca. A narcotic drug, formed of the leaves of the *Erythroxylon coca*, masticated by the Indians of the Peruvian and Bolivian Andes into small balls, called *acullicos*, and mixed with lime. It is said to enable those who chew it to undergo great fatigue for long periods without food. Tschudi found it the best preventive of the asthmatic symptoms caused by the rapid ascent of high mountains. The immoderate use of these leaves is attended with consequences similar to those produced by opium-eating or dram-drinking. Professor Wöhler of Göttingen has described *cocain*, its vegetable alkaloid.

Coccinella (dim. of Lat. *coccinus*, *crimson*). A genus of Trimerous Coleopterous insects, including many small species, usually ornamented with scarlet spots, and familiarly known as lady-birds, lady-cows, &c. In France these small beetles are dedicated to the Virgin, and called Bêtes de la Vierge. They are, in fact, of great service to the agriculturist, and especially to the hop-grower; for they destroy the *Aphids*, or plant-lice, in vast numbers, feeding on them both in the larva and perfect state.

Coccinite. A protiodide of mercury resembling Cinnabar, found in reddish-brown particles, on selenide of mercury, at Casas Viejas in Mexico.

Coccolite (Gr. κόκκος, *a grain*, and λίθος, *stone*). A kind of Pyroxene, found in small translucent granules of various shades of green, which are slightly coherent, and hard enough to scratch glass. It is chiefly met with in the iron mines of Sweden and Norway.

Cocoon or **Cocoon.** The silken case which the larvæ of certain insects spin for the purpose of a covering during the period of their metamorphosis, and which some spiders prepare as a protection to their ova during the development of the young. The cod or cocoon of the silkworm is a well-known example of the most valuable of these productions.

Cocosteus (Gr. κόκκος, *berry*, and στήν, *bone*). A genus of Placogonoid Devonian fishes in which the external ganoid surface of the buckler plates is ornamented with small hemispherical tubercles, whence the generic name. In all the palæozoic fishes the cylindrical gelatinous body called *notochord* or *chorda dorsalis*, pre-existing to the formation of the bony bodies of the vertebrae in all vertebrate animals, is never developed beyond the soft embryonal state; such fishes are accordingly termed *notochordal* as retaining the notochord.

Cocculus Indicus. The fruit of the *Anamirta Cocculus*. It is imported from the East Indies, and contains a poisonous principle, which has been termed *picROTOXIA*. It is often used to poison fishes: a few handfuls of it ground into coarse powder, and thrown into a pond, bring the fish, in the course of a few hours, to the surface in an intoxicated or poisoned state; but if quickly removed into fresh water, they recover. It is sometimes added to ale to increase its stupefying quality.

Coccum. In Botany, a term applied by Gertner to denote a pericarp of dry elastic pieces or cocci, as in *Diosma*, &c.

Coccus (Lat. *coccum*, *scarlet*). A name given by Linnæus to a genus of Hemipterous insects, including the Mexican species, the cochineal insect (*Coccus Cacti*, Linn.), which feeds on *Cactæ*, and which affords the well-known fine red dye.

Cochineal. The *Coccus Cacti*. This valuable insect was first introduced into Europe about the year 1523. It is imported from Mexico and New Spain. It feeds on several species of cactus. It is small, rugose, and of a deep mulberry colour. They are scraped from the plants into bags, killed by boiling water, and dried in the sun. Those are preferred which are plump, of a peculiar silvery appearance, and which yield a brilliant crimson when rubbed to powder. Cochineal is sometimes adulterated by the admixture of a manufactured article composed of coloured dough. This is detected by the action of boiling water, which dissolves and disintegrates the imitation, but has little effect upon the real insect. The

principal component of cochineal is a peculiar colouring matter, which has been called *carminium* and *cochinella*. It is obtained by digesting the powder of cochineal first in ether, which takes up fat, and then in alcohol, which dissolves the cochinelina. Acids change its colour from crimson to an orange-red, and alkalis turn it violet. When mixed with recently precipitated alumina, it forms a beautiful lake. Cochineal yields a brilliant scarlet dye, which is produced by fixing the colouring matter of the insect by a mordant of alumina and oxide of tin, and exalting the colour by the action of supertartrate of potash.

Cochlea (Lat. *shell*). In Anatomy, a portion of the internal ear, which in mammals is shaped like the common snail-shell, with its base resting on the bottom of the internal meatus, and perforated to receive some filaments of the acoustic nerve. It is traversed by a conical column, called *modiolus*, around which a *spiral canal* makes two turns and a half. This canal is divided into two ramps, or *scala*, by a partition of bone called the *lamina spiralis*. At the base of the cochlea one scala communicates with the vestibule, the other with the tympanum; they communicate with each other at the apex of the cochlea.

Cochlear (Lat. *a spoon*). In Botany, a term used in describing the aestivation of a flower, to express one piece being larger than the others, and hollowed like a helmet or bowl, covering all the others, as in *Aconitum*, &c.

Cochleate (Lat. *cochlea*, *a shell*, *a cockle*). In Botany, a term used in describing the general form of bodies, to denote any that are twisted in a short spire, so as to resemble the convolutions of a snail-shell; as the pod of *Medicago cochleata*. It also means a concave body like that of one of the valves of a cockle-shell, as in *Epidendrum cochleatum*.

Cocinic Acid. When the solid fatty matter of cocoa-nut oil is saponified, the crystalline fatty acid into which it is converted has been called *cocinic* or *cocostearic acid*.

Cock-pit. The after part of the orlop-deck, or deck below the lower deck, and altogether below the water. Here, in line-of-battle ships, are the cabins of several of the junior officers. The cock-pit is appropriated to the use of the wounded in time of action.

Cock-pit. The name given to the place where game cocks fight their battles. The room in Westminster in which her majesty's privy council hold their sittings is called the *cock-pit*, from its having been the site of what was formerly the cock-pit belonging to the palace at Whitehall.

Cock-up Letter. In Printing, a large type used for the first letter of the first word of a volume, part, book, or chapter. The bottom of the type must range with the foot of the other types in the line, otherwise it is called a *drop* or *two-line letter*.

Cocket. In Commerce, a scroll of parchment, sealed and delivered by the officers of the customs-house to merchants upon entering

COCKNEY

their goods, to certify that their merchandise is customed and may be discharged.

Cockney. A contemptuous appellation for a citizen of London. If the origin of the term be doubtful, its antiquity cannot be disputed, as it is mentioned in some verses generally attributed to Hugh Bagot, earl of Norfolk, in the reign of Henry II. :—

Were I in my castle at Bungey,
Upon the river of Waverney,
I would ne care for the king of Cockney (i.e. of London).

Cocoa. The fruit of the *Theobroma Cacao*, which is about the size of a kidney-bean, and enclosed in a thin shell.

Cocos (Port. coco, a monkey, from the resemblance of the end of the nut to a monkey's head). The Cocoa-nut tree, *C. nucifera*, is the type of this genus of palms, which mostly occurs in the tropical regions of America. The common Cocoa-nut, however, though now cultivated throughout the tropics, is supposed to be a native of Southern India. It prefers the vicinity of the sea, and hence probably its wide distribution. It forms a trunk 60 or 100 feet high, with a crown of pinnate leaves and branching spikes of from 12 to 20 fruits, three-sided with an outer fibrous husk enclosing a single seed contained in a hard shell, which is the form in which it is commonly known in this country. The uses of this palm are very numerous, every part being put to some purpose. The nut itself, the oil, and the fibre (called *coir*) are the principal products of the fruit; the trunk yields timber, and the leaves form mats, baskets, and thatch; while the sap yields toddy and palm sugar.

Cocytus (Gr. *κκυτός*, lamentation; from *κένω*, I bewail). In Mythology, one of the rivers of Hades; according to Homer, a branch of the Styx. (*Odyssey* x. 513.)

Cod Liver Oil. The oil obtained from the liver of the common cod (*Morhua vulgaris*), and other allied species, has long been a popular remedy for rheumatism and some other complaints, but its use by medical practitioners is of comparatively recent date. The London market is almost entirely supplied with this article from Newfoundland, where the fishing begins in June and ends in October. The livers are either pressed or they are boiled in water, and the oil afterwards filtered, the colour of it varying according to the mode of preparation and the species of fish from which it is derived. Besides the usual constituents of fish oil, traces of bromine and of iodine (iodide of copper) are said to have been discovered in it, and to these agents its efficacy may perhaps be ascribed, though it has often been doubted whether it possesses any virtues beyond those of the fat oils in general. In the dose of a tablespoonful or two daily, it generally acts slightly on the bowels; and though nauseous and disagreeable at first, the repugnance to it is soon overcome. Rheumatism, scrofula, chronic gout, skin affections, phthisis, and mesenteric emaciation are

CODEINE

the diseases in which it has been principally prescribed. One or two tablespoonfuls twice or three times a day for adults, and a teaspoonful night and morning for young children, are the usual doses. Coffee, warm table-beer, dill, peppermint, and other aromatic waters, are the best vehicles for covering its nauseous flavour.

Code (Ital. *a tail*). In Music, the passage which serves to close or end a movement, after the regular form has been completed. In some cases it consists of merely one phrase, in others it is carried to a great extent. At the conclusion of a canon, it often serves to end the piece which might otherwise be carried on to infinity.

Code (from the Latin *codex*, a manuscript). Signifies, in the language of Jurisprudence, any collection of laws digested and reduced into an orderly arrangement, whether by public authority or by the private labour of learned men. But, in the ordinary sense, the word *code* is only used to signify a compilation of laws by authority. Five collections of Roman law are designated by the title of *codes*: that of Sextus Papirius, which only exists in fragments discovered by various authors, but which contained the laws of the Roman kings; the Gregorian, the compilation of an unknown author, about the reign of Constantine; the Hermogenian, of which the author is also doubtful, and the date nearly the same; the Theodosian, framed under the order of the emperor Theodosius the younger, and containing the constitutions of the emperors from the time of Constantine to his own (from which, until the greater works of Justinian became publicly known in modern Europe, the juriconsults of the dark ages drew the greater part of their knowledge of Roman law); and, lastly, that of Justinian, A.D. 529. Of the codes of law now recognised in modern states the most remarkable are, in order of time: the code of Frederick the Great of Prussia; that of Catherine of Russia, confined to criminal jurisprudence; that of Joseph II. of Austria; and the Code Napoléon in France. This title, though sometimes given in general language to all the digests of law made under that emperor, is appropriated by French lawyers to the greatest of his works, the Code Civil. The project for this code was drawn up, in 1801, by five commissioners, by them reported to the Court of Cassation, and thence carried to the Conseil d'État: in that body it was fully discussed, clause by clause. Besides the Code Civil, the written French law now comprises seven other 'principal' codes; viz. the Code Pénal; the two Codes of Procedure, civil and criminal; the Code de Commerce; the Code Rural, Forestier, and 'de Pêche Fluviale.' Other collections of laws on special subjects are sometimes, but less accurately, termed, in France, *codes*; e.g. the Code Politique, Militaire, &c.

Codeine or Codéine (Gr. *κόδαινα*, the poppy head). An alkaline substance, discovered in 1832 by Robiquet in opium. It was at first confounded with morphia.

CODETTA

Codetta (Ital. dim. of coda). In Music, a short passage which connects one section with another, and not composing part of a regular section.

Codex (Lat.). A manuscript: in its original sense the inner bark of a tree, which was used for the purposes of writing. The word was thence transferred by the Romans to signify a piece of writing, on whatever material; e.g. with the stylus on tablets lined with wax, or on a roll of parchment or paper. In modern Latin, a manuscript volume. *Codex rescriptus* or *palimpsestus* is a manuscript consisting of leaves, from which some earlier writing has been erased in order to afford room for the insertion of more recent writing. Many such codices exist; and from the imperfect nature of the erasing process, the earlier writing has in some instances been restored. Considerable fragments of classical works, previously considered as lost, have been thus recovered by Mai from the contents of the Ambrosian Library at Milan.

Codicill (Lat. codicillus, dim. of codex). In Law, an addition or supplement to a will, for the purpose of altering, explaining, or adding to its contents. Of codicils, as of wills, the latter prevails where it contains provisions contradictory to those of a former. By the recent Wills Act (1 Vict. c. 26), every codicil must be executed in the same manner as is thereby made requisite in the case of a will; viz. signed by the testator in the presence of two witnesses present at the same time. [WILL.]

Coefficient (Lat. co, and efficio, I effect). In Algebra, one of two, simple or compound, factors whose product constitutes a term. Thus in the term $2ab^2c$, $2ab^2$ is the coefficient of c , $2a$ of b^2 and 2 of ab^2 . In the latter case 2 is frequently called the *numerical coefficient* of the term, the others being distinguished as *literal coefficients*. In an algebraical expression, and especially in quantities whose terms involve constant as well as variable factors, it is usual to restrict the term *coefficient* to the former and to refer to the latter as *facients*.

Coefficients, Laplace's. [LAPLACE'S COEFFICIENTS AND FUNCTIONS.]

Cochorn Mortar. A small mortar made of bronze, introduced by the great engineer Cochorn: very portable and useful.

Colecanthideæ (Gr. *κοίλος*, hollow, and *κανθα*, a spine). A family of Ganoid fishes in the system of Agassiz; so called on account of the species composing it being armed with hollow spines. The fossil genera, *Holoptychius* and *Colecanthus* proper, belong to this family.

Colelmintha (Gr. *κοίλος*, and *ἐλμιν*, a worm). The name of a class of Entozoa, including part of the cavitary intestinal worms of Cuvier, or those which are characterised by having an alimentary canal contained in a distinct abdominal cavity.

Coelenterata (*κοίλος*, concave, and *έντερον*, intestine). A sub-kingdom proposed by some zoologists to include all those animals in which a large internal or 'somatic' cavity is con-

COFFERDAM

stantly present, and whose body-substance resolves itself into two foundation membranes or layers, one serving the purpose of an integument, the other lining the large internal cavity. It is composed of the two orders *Hydrozoa* and *Actinozoa*, and includes the *Zoophyta*, *Medusideæ*, *Sertularideæ*, Corals, *Actinieæ*, &c. All the *Coelenterata* are marine, with the exception of two freshwater genera (the *Hydra* or polyps), and they are generally distributed throughout most seas. Indications of the animals comprised under the term *Coelenterata* will be found under the heads *ACALEPHÆ*, *ANTHOZOA*, and *HYDROZOA*.

Coliac (Gr. *κοίλα*, the belly). A painful species of diarrhœa has been by some medical writers called the *coliac passion*. The *colic artery* is the first branch of the aorta in the abdomen.

Cœnaculum (Lat.). In ancient Architecture, the eating or supper room of the Romans. When it became the fashion to dine in the upper rooms, the whole upper story of their houses, which rarely consisted of more than two stories, was often called by this name.

Cœnobile. [CENOBIO.]

Cœnobite or **Cœnobile** (Gr. *κοινόβιος*). One who lives under a rule in a religious community, as distinguished from an anchorite or hermit, who lives in solitude. [ASCUOINET.]

Cœnure, **Cœnurus** (Gr. *κύων*, and *οὐρα*, a tail). The hydatid which infests the brain of sheep is so called, because the dilated cyst is the common termination or basis of attachment of many heads and bodies. The disease called *staggers* is produced by this parasite.

Coffea (from Caffa, or Kuffa, the name of an Abyssinian province where the tree is found). The genus which contains the Coffee-tree, a member of the great Cinchonaceous order. This plant, the *Coffea arabica*, is a shrub or small tree twenty feet high, with opposite oblong oval leaves, and clusters of small white flowers in their axils, succeeded by red fleshy berries resembling small cherries, each containing two seeds. The coffee shrub is cultivated throughout the tropics, and is the source of considerable trade, upwards of 60,000,000 pounds being in some years imported to this country, of which more than half is retained for home consumption.

Coffee. The berries of the *Coffea arabica*. These, when roasted, powdered, and infused in boiling water, yield the well-known beverage called *coffee*. It is exhilarating, and operates upon many persons as an aperient. [CAFFEIN.]

Coffer (Fr. *coffre*). In Architecture, this term is applied to the sunk panels in vaults and domes, and also in the soffit, or under side of the Corinthian cornice, usually decorated in the centre with a flower.

Cofferdam. A water-tight case made for the purpose of excluding the water from such work as the wall of a wharf, the pier of a bridge, &c., in order that it may be executed in the dry. A cofferdam is composed of one or more rows of piles, usually of two, between which clay or some impermeable material is

COGS

driven; the piles, generally driven close together, are sometimes grooved and tongued, or dovetailed, or if the water be not very deep the piles are driven five or six feet apart and grooved, with boards or plates let into the grooves; but the effectual exclusion of the water is the essential condition of a cofferdam, and great pains must be taken to prevent the passage of water through the joints, and upon the line of junction with the natural soil. The general formula given by Neville (*Civil Engineer Journal*, 1840, iii. 78) is as follows,

when there are no stays: $d = \frac{\sqrt{125a^3}}{3.b.s.}$; in

which d = the thickness of the dam in clear of piles; c = the depth of water in feet; b = the height of dam in feet; s = the weight of a cubic foot of the dam usually = ninety pounds. (Mosely's *Mechanical Principles of Engineering*, &c.)

Cogs. In Millwork, the term *cogs* is given to the teeth of wheels when they are not of the same piece with the body of the wheel, but are each of a particular piece.

Cognisance. In Heraldry, a crest, coat of arms, or similar badge of distinction, appertaining to a person or family.

Cognisance, Conscience (Lat. *cognoceo, I know*). In Law, an acknowledgment of a fine, of taking a distress, &c. It also signifies the power which a court has to hear and determine a particular species of suit.

Cognomen (Lat.). The last of the three names by which all Romans, at least those of good family, were designated, e.g. Publius Virgilius Maro. It served to mark the house [FAMILIA] to which they belonged, as the other two names, viz. the *prænomen* and *nomen*, served respectively to denote the individual and the class [GENE] to which his family belonged.

Cognovit (Lat.). In Law, is a confession whereby a defendant admits that the plaintiff's cause of action against him is just (*cognovit actionem*), and suffers judgment to be entered against him without trial.

Cogredient. Two sets of facients or variables, each set containing the same number, are said to be *cogredient* if on replacing the variables of the first set by certain linear functions of themselves, those of the second set become also replaced by the same linear functions of themselves. Thus the trilinear coordinates x, y, z , and x', y', z' , of two points in a plane are cogredient; for if after transformation to new axes the former become replaced respectively by $ax + by + cz, a_1x + b_1y + c_1z, a_2x + b_2y + c_2z$, the latter will obviously be changed to the same functions of x', y', z' .

Cohesion (Lat. *cohæreo, I hold together*). In Natural Philosophy, is the force or attraction with which the particles of homogeneous bodies are kept attached to each other, or with which they resist separation. Cohesion is thus distinguished from *adhesion*; the latter term denoting the attractive force existing between two different bodies brought into contact, as a

COHESION

drop of water on a plate of glass; or between two bodies of the same matter, as two lumps of lead, when their smooth surfaces have been pressed together. The three different forms which matter assumes—solid, liquid, and gaseous—are determined by the degree of cohesive force existing among the elementary particles. In solids this force is greatest, and, in fact, is that which causes solidity; in liquids it is less powerful, but still sufficiently manifest in the drops or globular forms assumed by small quantities of water or mercury poured on a table. In the case of æriform fluids it may be regarded as negative, the particles having a tendency to repel each other. The cohesive force of the elementary particles of matter depends on the distances of the particles from each other; but of the law according to which its intensity increases or diminishes nothing is known, excepting that the force decreases rapidly as the distance increases, and vanishes altogether when the distance becomes so great as to be appreciable to the senses.

It is a problem of very great importance to determine the cohesive power of the materials employed in mechanical structures. Many experiments have been made for this purpose; and their results have not only a practical utility, but throw much light on the constitution of bodies. When a bar of metal, a beam of wood, or a rope is stretched lengthwise, the tension which it bears, or the cohesive power exerted, is equal to the accumulated attraction of all the particles in any transverse section. The longitudinal distension which takes place before disruption is at first proportional to this attraction, but afterwards increases in a more rapid progression. 'A bar of soft iron will stretch uniformly by continuing to append to it equal weights till it be loaded with half as much as it can bear; beyond that limit, however, its extension will become doubled by each addition of the eighth part of the disruptive force. Suppose the bar to be an inch square, and 1,000 inches in length; 36,000 lbs. avoirdupois will draw it out one inch, but 45,000 lbs. will stretch it 2 inches, 54,000 lbs. 4 inches, 63,000 lbs. 8 inches, and 72,000 lbs. 16 inches, where it would finally break.' (Leslie's *Natural Philosophy*.)

The following is a tabular view of the absolute cohesion of the principal kinds of timber employed in building and carpentry, showing the load which would rend a prism of an inch square, and the length of the prism which, if suspended, would be torn asunder by its own weight:—

	lbs.	ft.
Teak . . .	12,915	36,049
Oak . . .	11,880	32,900
Sycamore . .	9,630	35,800
Beech . . .	12,225	38,940
Ash . . .	14,130	42,080
Elm . . .	9,720	39,050
Memel fir . .	9,540	40,500
Christiania deal	12,346	55,500
Larch . . .	12,240	42,160
	I I	

COHOBATION

The metals differ more widely from each other in their cohesive strength than the several species of wood or vegetable fibres. According to the experiments of Mr. George Rennie in 1817, the cohesive power of a rod an inch square of different metals, in pounds avoirdupois, with the corresponding length in feet, is as follows:—

	lbs.	ft.
Cast steel	134,268	39,455
Swedish malleable iron	72,064	19,749
English ditto	55,872	16,938
Cast iron	19,096	6,110
Cast copper	19,072	5,003
Yellow brass	17,958	5,180
Cast tin	4,736	1,496
Cast lead	1,824	348

Cohobation. The repeated distillation of the same liquid from the same materials. The term was invented by Paracelsus.

Cohort (Lat. *cohors*). The tenth part of a Roman legion. The *Prætorian cohort* was a body of picked troops who attended the general, and is said to have been first instituted by Scipio Africanus. [*Lægon*.]

Coil of a Gun. Is formed by winding a bar of iron at a welding heat round a mandrel, which is afterwards removed. The rough coil so formed is welded, bored, and turned to the required size. A great part of the Armstrong gun is formed of these coils.

Coins. [*NUMISMATICS*; *MONEY*]

Coin-weighing Machine. A machine for this purpose, patented by Mr. W. Cotton, was constructed by Mr. Napier for the Bank of England in 1844, and has since been more extensively applied at the Mint.

It consists of a square brass box, on the top of which is placed a hopper to hold the sovereigns to be weighed, and in front of it are two small apertures fitted with receivers, one for the sovereigns of full weight, and the other for light sovereigns. The balance for weighing the sovereigns is placed inside the box near the upper plate, vibrating upon a knife edge, and receiving the sovereigns upon a small platform at one end of the beam and above it. The platform is kept in its place by means of a small pendulum, on which, at about an inch below the platform, there is an oblong perforation, about half an inch in length, technically called a *slot*, in which a small ivory rod works freely up and down, without touching the sides.

Between the slot and the platform a pair of forceps is placed. From a knife-edge at the other end of the beam a small round polished plate is suspended, to which a pendulum is fixed, and at its lower part the scale is placed to receive the weight. Above the small round plate, under the top of the box, is fixed an agate with a blunt point. When the machine is in motion, the small ivory rod is depressed; this, on touching the bottom of the slot, or opening in the pendulum in which it works, brings down the beam on that side, and raises it of course on the other, the weight side, until the small round plate on that side touches the

COINAGE

agate point. The beam is then in a horizontal position. As soon as this is effected, the forceps catch hold of the pendulum between the platform and the slot, and hold it firmly. The balance is then in a condition to receive the sovereign, which is shifted from the bottom of the pile in the hopper, and brought by means of a slide along a channel, just large enough for a sovereign of the proper standard gold to pass, but not large enough to admit a counterfeit, and deposited upon the platform. The forceps then let go their hold, the ivory rod is gently raised, and, if the sovereign happens to be light, that end of the beam rises, and the other end leaves the agate point; but, if the sovereign be of full weight, the beam remains stationary, and the small plate on the weight end is in contact with the agate point.

When the sovereign is weighed, the operation of its removal is very ingenious, and is as follows: Two bolts are placed at right angles to each other, and on each side of the platform or scale there is a part cut away to admit of the bolts striking so far into the area of the platform as to remove anything that would nearly fill it. These bolts are made to strike at different elevations, the lower one striking (as to time) a little before the other. If the sovereign be of full weight the scale remains down, and the lower bolt knocks it off into the full-weight box. If the sovereign, on the other hand, be light, it rises up, and the first bolt strikes under and misses it, and the higher bolt then strikes and knocks it off into the light box. The machine weighs about thirty-three sovereigns in one minute. The weights used are of glass, and are adjusted to within the ten-thousandth part of a grain.

The preceding description applies to Mr. Cotton's weighing machines as originally adopted at the Bank of England, for the purpose of detecting light sovereigns. In the year 1852 a series of twelve of these machines, so constructed as to separate blanks, or coins of current weight, from those which are too heavy or too light, and to distribute the pieces thus weighed into three separate boxes, were made by Mr. Napier for the Royal Mint, and are now in constant and successful use. Any detailed description of these more complicated machines would be unintelligible without illustrative plates incompatible with this work. A representation and description of one of them will be found in an article on 'Coining' published in *Tomlinson's Cyclopædia*, 1862.

Coinage. Under this term we shall give a brief outline of the proceedings in reference to the manufacture of coin, as carried on in the Royal Mint of London.

When a parcel of gold is brought to the Mint in ingots, assays are made of each ingot; the importers are then required to attend at the Mint, to receive the assayer's reports, and a Mint bill is given, certifying the weight, fineness, and value of the ingots, and signed by the proper officers, which bill is returned upon the delivery of the bullion to the importers in the state of coin.

COINAGE

The bullion is then delivered to the melter, who guided by the assayer's report, adds either alloy or fine gold (when either are required), so as reduce the mass to *standard fineness* (that is parts of pure gold and 2 of alloy), and melt and casts the metal into bars of convenient form for rolling: each bar, when intended for coinage into sovereigns, being an inch and a half by one inch square, and about two feet in length, and weighing about 26 lbs. A piece is then taken from each extremity of each bar and delivered to the assayer, who ascertains that the said bars are of standard fineness before he allows them to be delivered for the purpose of coinage.

These preliminary operations are nearly the same as regards silver bullion.

The bars are then transferred to the Coining Department, where they are rolled and drawn into plates of proper thickness, which require to be most nicely adjusted, so that a piece of proper size punched out of any part of the plate may have the exact weight of the intended coin; the blanks are then cut out of these plates, which are thus reduced to the state of *scissel*, and remelted (under due checks and precautions), to be again cast into bars. The blanks (amounting to about two-thirds, and the scissel to one-third of the weight of the original plate or metal) are next annealed, and passed through the *marking machine*, by which the edge of each piece is made smooth and a little raised; they are then cleaned or *blanched* by being put for a few minutes into a hot and very dilute sulphuric acid, after which they are thoroughly washed and dried, and are ready to be *stamped* or coined. This operation is performed in presses moved by mechanical power, and consists in placing the blanks between two *stec-dies*, upon one of which is engraved the obverse and upon the other the reverse of the coin, so as to give an impression in relief; while the spreading of the piece in a lateral direction is prevented by the rising of a collar at the moment the blow is struck, in which collar is engraved the *milling*, which is thus transferred to the edge of the piece at the same moment that the impressions of the dies are taken upon its two surfaces. The coining presses at the Mint are usually attended by boys, who have only to fill a tube or species of hopper with the blanks; the operation of laying the blank upon the dies, and again throwing it off when stamped, being effected by the machinery connected with the press, thus preventing the risk of crushing the fingers of the persons who used to be employed in this department before these *layers on*, as they are technically called, were adopted. In the coining room at the Mint there are eight presses, each adapted for every species of coin; each press strikes upon an average 60 pieces per minute, or 3,600 per hour; so that in the day's work of 10 hours each press produces about 36,000 pieces; and the eight presses (supposing that they are all in use) stamp 288,000 pieces daily. The money when thus completed is weighed up in what are called *journey weights* for delivery to the importers of the bullion; the

COLA

gold in 15 lbs. and the silver in 60 lbs. troy. But before any coin is suffered to pass out of the Mint, it is inspected as to its workmanship; and if it be in any respect faulty or imperfect, is rejected for recoinage. The weight and fineness of the money are also ultimately examined and insured by the process of *pyxing*, which consists in taking promiscuously from every journey weight of coin a pound in tale, which is carefully weighed by the assay master, who declares aloud the *minus* or *plus* upon each pound (if it be not *standard* or *exact*), which is recorded by the comptroller and assayer. This determines whether the money has been made within the *remedy* allowed upon the pound troy; but, as the remedy upon the pound is divided among the number of pieces in it, the comptroller weighs several of the pieces individually, and if they are not within the allowed limits, can, in conjunction with the other check officers assembled on this duty, return the coin to the Coining Department, to be remelted and re-coined. From the same pound weight of gold or silver the comptroller also takes two pieces, one of which is handed to the chief assay-master to assay, in order to prove that the metal has undergone no deterioration in any of the processes of its manufacture; the other piece is sealed up in a packet and consigned to the *pyx* box, which is locked by the separate keys of the check officers, where it remains until the *trial of the pyx* by jury before the king or certain of his council, which usually takes place once every three or four years in the Court of Exchequer at Westminster.

The term *journey weight* is applied at the Mint to the weight of certain parcels of coin, which were probably considered formerly as a day's work. The journey of gold is 15 troy pounds, which is coined into 701 sovereigns, or 1,402 half-sovereigns. A journey of silver weighs 60 lbs. troy, and is coined into 792 crowns, or 1,584 half-crowns, or 1,980 florins, or 3,960 shillings, or 7,920 sixpences.

Coke. The charcoal obtained by heating coal with the imperfect access of air, or by its distillation. The former is usually called *oven coke*; the latter *gas coke*, being abundantly produced in gas-works. The weight of coke usually amounts to between 60 and 70 per cent. of the coal employed. Coke is a valuable fuel for many purposes in the arts.

Caking Coal. Those kinds of Bituminous Coal which it is necessary to convert into coke before they can be advantageously used in furnaces, in consequence of their caking in the fire. Most of the coal of Northumberland and Durham is of this quality. [CAKING COAL.]

Cola (Kola, the native African name). A small genus of *Stereuliaceae* inhabiting Western Tropical Africa. The fruit consists of two, sometimes more, separate pods (follicles), containing several seeds about the size of horse-henuts. Those of *C. acuminata* are called Kola, Cola, or Goora nuts, and are extensively used as a condiment by the African natives, as well as by the negroes of the West Indies and

COLCHICINE

Brazil, where the tree has been introduced. They are said to render half-putrid water drinkable. A considerable trade is carried on in Cola-nuts by the natives in the interior of Africa, the trees growing mostly near the coast.

Colchicine. An alkaloid obtained from, and probably constituting the active principle of the *Colchicum autumnale*. It was formerly confounded with *Veratrine*.

Colchicum (from Colchis in Armenia, where the plant is said to have abounded). This term is generally applied to the corm or bulb of the *Colchicum autumnale*, or Meadow Saffron, a plant common in this country, and largely collected for medical use. *Colchicum* belongs to the order *Melanthaceae*, and bears crocus-like flowers in autumn, followed in spring by shining sword-shaped leaves. It was much employed formerly as a diuretic in dropsy; it then fell into disuse, but it has been recently again largely prescribed for the cure of gout, the fact having been ascertained that the celebrated French remedy for gout called *Eau médicinale d'Huison* was a tincture of colchicum. When the corms are intended for medical use, they should be dug up in summer (July), and immediately cut into thin transverse slices, placed separately upon paper, and dried by a very gentle heat. The best preparation is the *wine of colchicum*, made by infusing an ounce and a half of the bulb prepared and dried as above, and coarsely powdered, in twelve ounces of sherry, for six or seven days, shaking it daily; then filter it for use. The dose is from 20 drops to 1 drachm, taken at bed-time in a little water. The seeds of colchicum are also official, and are, by some, preferred to the corms.

Coleothar. A red oxide of iron, being the residue of the distillation of green vitriol or sulphate of iron.

Cold Blast. The air forced through furnaces used for smelting iron at its natural temperature, is called a *cold blast*, in opposition to the *air blast*, which are heated by artificial means. The cast iron obtained by the cold blast is tougher and stronger than the hot-blast iron; it presents a closer texture and a smaller crystallisation than the latter; the specific gravity of cold-blast iron is less than that of the hot blast, and its modulus of elasticity appears also to be less.

Cold-blooded. In Zoology, those animals are so called which have a range of temperature from a little above the freezing-point to 90° Fahr. and upwards, and which follow the changes of the surrounding medium through that range. Almost all invertebrate animals, and fishes and reptiles amongst vertebrates, are cold-blooded in this sense.

Coleophyllum (Gr. *κολεός*, a sheath, and *φύλλον*, a leaf). A term introduced into Botany, to indicate a monocotyledonous structure, the young leaves being evolved from within a sheath, while those of Dicotyledons are always naked.

COLEOPTERANS

Coleopterans (Gr. *κολεόπτερα*, *sheath-winged*). The name of the order of insects comprehending those in which the first pair of wings have the consistence of horn, and serve as defensive coverings to the second pair, or true wings, which are of large size, and are folded transversely when not in use.

By means of this mechanism the *Coleoptera* are enabled to burrow in the soil, or bore the trunks of trees, without injury to their delicate organs of flight, which are the true or second pair of wings. These, being of ample size, are peculiarly folded, being bent at nearly right angles, so as to pack up in small compass beneath the elytra or wing-covers, when the beetle is at rest. In some species the membranous wings are wanting, but the elytra are always present; although in this case, as they are never required to be expanded for flight, they are generally soldered together by a straight suture at the middle line. In ordinary cases the inner straight margins of the wing-covers are simply but accurately applied to each other.

The *Coleopterans* are of all the orders of insects the most numerous, and the best known. Their singular forms, the brilliant and agreeable colours which many of them present, the large size of some of the species, the solid consistence of their teguments, which renders their preservation easy, and the regular series of affinities traceable through several of the groups, all combine to render them objects of particular interest and attention.

The head supports two antennæ of various forms, but almost always consisting of eleven joints. They have two compound eyes, but no ocelli. The mouth is composed of six principal pieces; of which four, called the mandibulæ and maxillæ, move transversely in pairs, while the remaining two are fixed, and close the mouth vertically. The uppermost of the two vertical pieces is called the *labrum*; the lowermost is termed the *labium*, and is itself subdivided into the *mentum* and *lingua*, and together with the maxillæ, or the lowest of the vertical pieces, supports a pair of articulated processes, called *palpi* or *feelers*.

The anterior segment of the thorax, or *manitrunk*, supports the first pair of feet, and greatly surpasses in extent the two other segments which form the *alitrunk*. The abdomen is sessile, and united to the trunk by a great part of its breadth. It is externally composed of six or seven wings.

The *tarsi* vary as to the number of their joints, in some *Coleoptera* having but three, in others four, in others five—modifications upon which Latreille founds his primary division of the order, Pentamera, Tetramera, Trimera.

The *Coleoptera* undergo a complete metamorphosis. The larva resembles a worm; the head is encased in a firm horny substance; the mouth is analogous in the number and functions of its parts to that of the perfect insects; it has also generally six feet, but some species have instead only simple tubercles. When perfect the larva generally burrows in the

earth, and excavates an oval cell, within which it undergoes its change into an inactive pupa; this is generally of a whitish colour, with the wings and legs folded upon the breast. The habitation and manner of life of these insects vary much, both in their immature and perfect stages. The affinities of the *Coleoptera* to the *Orthoptera* are of a closer and more manifest nature than can be traced between the *Coleoptera* and any other order of the mandibulate insects. The genus *Forficula* forms the intervening link. It was formerly placed by Linnæus at the end of the *Coleoptera*, and was subsequently referred by Latreille to the order *Orthoptera*; but now constitutes the type of an order apart and intermediate to these two. The absence in some ants of the wings, sting, and ocelli, has led Mr. Macleay to suspect that these *Hymenoptera* make an approach to the *Coleoptera*. Mr. Kirby would place the *Strepsiptera* in juxtaposition with the *Coleoptera*, observing that the metamorphosis in the former 'being different from that of *Orthoptera* and *Hemiptera*, and nearer to that of the *Coleoptera*, this seems its most natural station, considered as an Elytrophorous order.'

Coleoptilum (Gr. *κόλεις*, and *πτερον*, a feather). A term sometimes applied to the young leaves of Monocotyledons, from the circumstance of their always being developed within a sheath.

Coleorhiza (Gr. *κόλεις*, and *ρίζα*, a root). A term invented by Mirbel to denote the sheath within which the radicle of monocotyledonous plants is enclosed.

Colic (Gr. *κολικός*, from *κόλον*, the colon; one of the large intestines, the seat to which the principal pain is generally referred). There are many varieties of this complaint, and it arises from various causes, and exhibits different symptoms. The general indications of cure are to evacuate the bowels by the least irritating means, and, when the lower intestines are loaded, by the use of glysters; opiates and etherial remedies may be resorted to to allay spasms, and warm bath and fomentations are often necessary.

There is a peculiar disease called the *painter's colic* or *dry bellyache*, which appears to arise from the absorption of lead into the system, and which therefore commonly attacks plumbers, painters, and makers of white paint and other colours and preparations in which lead is used; the persons employed in the lead mines and furnaces are also subject to it. It is often named from certain places in which it is peculiarly prevalent; as Poitou, Devonshire colic, &c. It begins with restlessness and uneasiness about the stomach, nausea, and obstinate costiveness. There is general spasm of the bowels, often accompanied by great pain, which is somewhat relieved by pressure; and this circumstance enables us to distinguish the complaint in question from inflammation of the bowels; into which, however, it runs, if not relieved by opiates, emollient glysters, warm bath, and gentle aperients,

especially castor oil when it will remain on the stomach, by which the spasm is allayed and the bowels evacuated of their hardened and irritating feces. This is the *acute* state of the disease; but it often occurs in a *chronic* form, in which case pains and constipation of the bowels are followed by occasional delirium, epilepsy, paralysis, especially of the hands, and wasting away of the muscles. This disease often terminates fatally. The patient should always be cautiously removed from all contact with lead, and allowed fresh air and a nutritious but not stimulating diet.

Collisem. [*AMPHITERATR.*]

Collapse (Lat. *collapsus*, part. of *collabor*, I shrink down). A wasting of the body; or a sudden and extreme depression of its strength and energies.

Collar (Lat. *collum*, the neck). A peculiar badge worn round the neck by knights of different orders. It consists of a gold chain, enamelled, &c., to which is attached the badge of the order of knighthood; and it is worn at court chiefly on state occasions, which are thence called *collar days*.

COLLAR. In Architecture, a horizontal piece of timber connecting two rafters.

COLLAR. In Malacology, the thickened secreting margin of the mantle in the testaceous Gastropods.

COLLAR. In Ornithology, the coloured ring round the neck of birds.

Collar-beam. A piece of timber connecting opposite principal rafters, or the small rafters of a roof, and placed above the level of the feet of the rafters. The name is also generally given to the straining piece of a queen post truss.

Collateral Circulation. In Physiology, the passage of the blood from one part to another of the same system of vessels by collateral communicating channels; it is much more frequent in the veins than in the arteries.

Collect. A term, of doubtful derivation, applied to certain short prayers found in the liturgies of all churches. (*Hook's Church Dictionary.*)

Collectanea (Lat.). A term applied, in Literature, to a selection of passages made from various authors, usually for the purpose of instruction.

Collectors. In Botany, dense hairs covering the styles of some species of *Compositæ*, &c., and acting as brushes to clear the pollen out of the cells of the anthers.

College (Lat. *collegium*). According to the primary meaning of the word, any society or number of persons bound together by the same laws or customs (*Collegæ, collegues*). Among the Romans, not only societies invested with a character resembling that of modern corporations, enjoying certain political rights in common (as the colleges of augurs, pontifices, &c.), were termed *collegia*; but bodies of men who appear to have had no bond of union except common employment (as the *collegia opificum*, or colleges of the different trades) were also thus

COLLEGE

designated. Hence has originated the erroneous notion that the guilds of modern Europe were derived from similar institutions among the ancients, by attributing to the last-mentioned *collegia* a corporate character, which it is not sufficiently proved that they possessed; although some of these bodies, as we learn from the fragments of the lawyer Gaius, did in effect hold common property, and had their affairs administered by by-laws of their own. In England many corporate bodies are termed *colleges*; e.g. the colleges of physicians and surgeons, of heralds, &c. &c. A college, in the academical meaning of the word, signifies a society established for academic purposes under royal or private foundation, endowed with revenues, and subject to a private code of laws. Where such a society possesses within itself all the means of instruction and the rights and faculties which are incident to a university, the terms *university* and *college* are among ourselves convertible, and indiscriminately used. Thus, Trinity College, Dublin, affords a specimen of an institution called indiscriminately by either title. On the other hand, the universities of Oxford and Cambridge are composed of a number of colleges united together under the same discipline and government, and in which those powers peculiarly belonging to a university are wielded by one class of authorities, the functions of the colleges being superintended by another. The Scottish universities, not being in the strict sense of the words endowed societies (i.e. not possessing a regular body of fellows and scholars receiving stipends), cannot be properly termed collegiate bodies.

The early history of colleges is somewhat obscure; although there can be no doubt that they were originally founded, in the various universities of the middle ages, with similar objects and from the same charitable motives. The first students at these universities assembled together under no common bond of union, except that of academic study and discipline, and lodged as suited their own convenience. Next, hostels or boarding-houses were established (in the first instance, it is said, by the religious orders for students of their own fraternities); in which the scholars lodged together under certain superintendence. Charitable individuals afterwards endowed these hostels, for the purpose of providing poor scholars with free lodgings. Finally, to these endowments were added (by gifts or bequests) stipends for all or a certain number of the scholars frequenting these inns or hostels; and thus the foundation of a college was completed. The distinction of language arising from ancient usages is still preserved at Oxford, where societies endowed for the maintenance of fellows and scholars are termed *colleges*; societies unprovided with such endowments, *halls*. But at Cambridge there is no distinction between *colleges* and *halls*. At the university of Paris fifteen colleges, or more, are said to have been founded in the thirteenth century; and the whole number, in the course of time, amounted

to eighteen greater and about eighty lesser. But these institutions assumed a different shape from that which they took in England. The greater colleges became appropriated to particular faculties, or departments of a faculty. Thus, for example, the Sorbonne was the college of the theological faculty; and, in process of time, the lectures and disputations of most of the faculties became confined to the walls of those colleges which were exclusively devoted to them. Hence the university became, in fact, a collection of academies for instruction in particular subjects, and its corporate character for purposes of education vanished altogether as early as the fifteenth century; and the word *college*, in France, has now come to signify, in popular language, the higher order of schools. (See Malden, *On the Origin of Universities*, and the authorities there cited.)

The name and institution of colleges were derived by the English universities, together with most of their other peculiarities, from Paris; but their history is very different. The colleges now subsisting in the English universities were constituted by royal or private munificence; either as original foundations, or (more commonly) by the endowment of formerly subsisting halls or hostels with stipends for students. They were all formed on the same principle, consisting of a head (variously termed *master*, *principal*, *provost*, &c.) and of a body of fellows and scholars. The colleges were thus founded simply for the purpose of assisting scholars in their progress through the university, not for that of conferring instruction. All those of Catholic foundation, it must be added, were intended to supply the church with ministers; hence the still subsisting or but recently modified regulations prohibiting the marriage of fellows. In the course of time independent members, i.e. members not upon the foundation nor sharing in the endowments, were admitted to reside within the walls of the colleges; and the task of superintending, and finally of instructing them, was gradually transferred from the university authorities to those appointed by and resident within the colleges. By the present constitution of the two English universities, the only powers retained by the university as such are of a general character, as of conferring degrees and other honours, &c. &c.; while the function of education for the purpose of qualifying for those degrees has entirely passed into the hands of the colleges of which the entire body is composed, every member of the university being now, by usage which has acquired the force of law, also member of some college or hall. With respect to discipline and government, the power is shared between the university, which through its vice-chancellor and proctors exercises a general superintendence, and the colleges, which by their own officers maintain order within their own walls. A college, therefore, in the sense in which the term is applied at Oxford and Cambridge, has a double character—1. As an endowed society;

COLLEGE OF JUSTICE

2. As a house of education. In the first sense, the college is composed of the head, fellows, and scholars. It is under the government of the original laws framed by its founder, with such variations as in some cases time has introduced; but alteration is always jealously watched. According to the tenure of these statutes, the head is either chosen by the fellows from among themselves, or in some instances appointed by the crown or other authority. The fellows, again (who are mostly, but not universally, graduates who have passed the lowest degree, that of Bachelor of Arts), and the scholars, who are admitted when undergraduates, are either chosen from particular localities, schools, &c. &c., according to the will of the founder, or elected according to merit after free competition between members of the college or of the university at large. Every college is finally under the superintendence of a visitor, generally some high ecclesiastical functionary. 2. As a place of education, the college receives within its walls not only fellows and scholars, but also (in the great majority of instances) independent members, limited in number only by the extent of the lodging which it can afford; it being usual at Oxford (although not at Cambridge) that every student on entering the university should not only belong to a college or hall, but reside within its walls. The undergraduate members of the college are under the superintendence of the tutors. These are, in general, resident fellows, appointed by the head to perform this office. In some colleges each tutor has under his special control a certain number of undergraduates; in others the tutors divide among them, not the students, but the different branches of instruction which are to be communicated. Such is a very general outline of the system of English colleges; but each of these foundations is exclusively governed by its own laws and usages, and no comprehensive description will apply without exception to all. Oxford has nineteen colleges and five halls; Cambridge seventeen colleges or halls. In both universities the oldest are supposed to have existed from the middle of the thirteenth century; the greater part were founded between that period and the Reformation, but a few are of Protestant foundation. [UNIVERSITY.]

College of Justice. In Scottish Law, a term applied to the supreme civil courts, composed of the lords of council and session; together with the advocates, clerks of session, clerks of the bills, writers to the signet, &c. [Ssesrow.]

Collegiate Church. In English Ecclesiastical Law, a church, not a cathedral, having an endowment for a society or body corporate consisting of a dean and chapter.

Collet. [COLLUM.]

Collidine. An organic base found in bone-oil.

Collimation (Lat. *collimo*, *I aim at*). The line of collimation, in a telescope, is the line of sight, or the straight line which passes

COLLISION

through the centre of the object-glass and the intersection of the wires placed in its focus. The error of collimation is the difference between the actual line of sight and the position which that line ought to have in reference to the instrument.

Collimator. A fixed telescope with a system of wires at its focus. If the cross-wires of the collimator be illuminated, the rays from them will issue parallel, and consequently be in a fit state to be brought to a focus by the object-glass of any other telescope, in which they will form an image as if they came from a celestial object. Hence the intersection of the cross-wires of the collimator may be used as a standard point of reference, always visible, and the least change in the position of a movable instrument in any direction observed. In large observatories the transit collimators are arranged opposite each other, so that when the large telescope is raised, the image of the cross-wires of the other is viewed superposed, or nearly so, on the system proper to each: when the large telescope is in position, it can look into both. By these means, in a reversible instrument, all errors or changes of position may be detected.

Captain Kater's floating collimator consists of a telescope kept either in a horizontal or vertical position by resting on a float in mercury. This arrangement for fixing the zenith and nadir points is now, however, superseded by reflection from the surface of mercury. We may also add that a recent addition to the transit, devised by Mr. Cook of York, which consists in fixing levels of extreme delicacy to the telescope, bids fair in time to supersede the use of collimators to a very great extent. (Pearson's *Practical Astronomy*, vol. ii.)

Collinear (Lat. *con*, and *linea*, a line). Two figures, or systems of points, are said to be *collinear*, when the relation between them is such that to any point in either system corresponds but one point in the other, whilst to the several points of a right line in either system correspond those of a right line in the other system. In establishing such a relation between two *plane* figures, four pairs of corresponding points may be chosen arbitrarily; this being done, however, all other pairs are defined. It is always possible to give the planes of two collinear figures such a position, that the one figure shall be the projection of the other with respect to some centre of projection in space. The term *collinear* appears to have originated with Möbius, in whose *Barycentric Calculus* the nature of this relation is thoroughly examined. It includes the relations of *affinity* and *similarity*, and is identical with the *homographic* relation, as originally defined by Chasles (*Géométrie Supérieure*).

Colligative (Lat. *colligesco*, *I melt*). Excessive evacuations are so termed, which appear to melt down the strength and substance of the body.

Collision (Lat. *collido*, *I strike against*). In Mechanics, the impact of two bodies, one or

COLLODION

both of which were previously in motion. The laws of the direct impact of two spherical bodies are deduced from the principle that the sum of the momenta of the impinging bodies, estimated in a fixed direction along the line of motion, is not altered by the collision. The velocities of the bodies after impact, however, depend upon the hardness and elasticity of these bodies. If perfectly hard, they will move, after impact, as one body with a velocity, and in a direction, which is ascertained by dividing the algebraical sum of their previous momenta by that of their masses. If not perfectly hard, a certain compression takes place on collision, and is immediately followed by a more or less perfect restitution of form, according to the degrees of elasticity which the bodies possess. In the case of perfectly elastic bodies this force of restitution is equal to that of compression, and the loss or gain in the velocity of each body which occurred at the moment of collision or commencement of compression, at which moment the bodies may still be regarded as perfectly hard, is precisely repeated. Thus if m and m' denote the masses of two bodies whose velocities v and v' are considered as positive or negative according to the direction of the motion, then in the case of perfect hardness the final velocity after impact would be $V = \frac{mv + m'v'}{m + m'}$; $V - v$ and $V - v'$, therefore,

are the increments in velocity which, in perfectly elastic bodies, are repeated so as to produce the final velocities $2V - v$ and $2V - v'$ respectively. In the case of imperfectly elastic bodies, the final velocities would be $V + e(V - v)$ and $V + e(V - v')$, where the constant *proper fraction* e depends upon the elasticity of the bodies, and must be ascertained by experiment.

In all cases of collision the state of the centre of gravity, whether at rest or in motion, remains the same after the impact as it was before. If it was at rest, it remains in that state; and if it was in motion, it continues to move in the same direction with the same velocity, notwithstanding the impact. This is the case both in respect of non-elastic and elastic bodies; and it is a constant law in whatever manner the bodies act on each other, and whatever be their respective natures.

All good text-books on mechanics treat the problem of the collision of bodies at considerable length; we must refer the reader to them for particulars concerning oblique impact, where the common normal to the impinging bodies at their point of impact no longer coincides with the line of motion.

Collodion (Gr. *κόλλα, glue*). A term applied, in consequence of its adhesive properties, to a solution of gun-cotton in ether. It is now largely used by photographic artists.

Colloids. When a solution of common salt in water is placed at the bottom of a jar, pure water poured gradually over it so as not to be mechanically mixed with the salt solution, and the whole set aside, diffusion of the salt up into the water commences at once and pro-

COLOCYNTH

ceeds with a certain rapidity. But if white of egg instead of solution of salt be employed, an equal amount of diffusion will require a period fifty times longer than that occupied by the salt. Gelatine is another substance which diffuses into water so slowly that the purest form of it, which is termed *collin*, is taken as the type of all similar substances, which are hence called *colloids*. Crystalline bodies diffuse with greatest rapidity; hence substances which are not colloids are known as *crystalloids*.

Colloids are highly susceptible of change. It is, therefore, not surprising to find that the organic proximate principles of food, substances that obviously must admit of easy assimilation, are colloids. Under certain conditions, also, silica, alumina, and peroxide of iron are colloids. Other facts concerning this class of bodies will be found under *DIALYSIS*.

Collum (Lat. *the neck*). That part of the axis of a plant whence the stem and root diverge. In the beginning it is a space which there is no difficulty in distinguishing, so long as the embryo or young plant has not undergone any considerable change; but in the process of time it is externally obliterated, so as to become a mere matter of theory.

Collutorium (a word coined from Lat. *colluo, I wash*, and *os, the mouth*). A lotion for rinsing the mouth.

Collyridians (Gr. *κόλλυρις, a roll of bread*). A sect of the fourth century found in Thrace and Arabia, so called from their offering little cakes in honour of the Virgin Mary.

Collyrite (Gr. *κόλλα, glue*; from its gelatinous appearance). A hydrated silicate of alumina. It is found at Ezquerra in the Pyrenees, near Schemnitz in Hungary, and in porphyry at Wissenfels in Saxony. A variety is also found in agglomerated masses, often stained red externally with oxide of iron; porous and easily friable, filling fissures in an old pit in the Upper Chalk, at Hove, near Brighton. The name *Hovite* has been proposed for this variety.

Collyrium (Gr. *κόλλυριον*). Lotions intended to check inordinate discharges. The term is now exclusively applied to *eye-waters*.

Coloboma (Gr. *κολοβός, I shorten*). The adhesion of the eyelids. Congenital fissures of the upper eyelid.

Colobus (Gr. *κολοβός, mutilated*). A genus of long-tailed Quadrumanes, or monkeys; so called, because the fore hands are deficient in, and, as it were, mutilated of, a thumb. In this respect the *Colobi*, which are exclusively limited to the African continent, resemble the spider-monkeys (*Atelæ*) of South America; but they have not a prehensile tail to compensate for the imperfection of the hands; their long caudal appendage is, on the contrary, terminated by a tuft of hair. The *Colobi* differ also from the *Atelæ* in having five molar teeth instead of six on each side of each jaw, and in having cheek-pouches.

Colocynth (Lat. *colocynthia*, Gr. *κολοκύνθη*). This term is applied in the Materia

COLOGNE EARTH

Medica to the pith of the Bitter Apple, the fruit of the *Ostrullus Colocynthis*, which is violently purgative. It is imported dried, and generally peeled, from Turkey, and is rarely used alone. One of the most valuable purgatives is the compound extract of *colocynthis*, which is a combination of this drug with aloe, scammony, cardamom seeds, and soap.

Cologne Earth. A deep brown pigment, or species of Umber; supposed to be of vegetable origin.

Colembia. The neutral active principle of Calumba Root.

Colem (Gr.). This name is given to the greater part of the large intestines: the colon passes upwards towards the liver, forming the *transverse arch* which descends upon the left side, and forms its *sigmoid flexure*; entering the pelvis, it passes into the *rectum*.

COLON. In Grammar. [PUNCTUATION.]

Colonel (a word of doubtful origin). The responsible command of every battalion of a regiment of infantry and every regiment of cavalry is vested in a lieutenant-colonel. Every lieutenant-colonel after five years in command becomes a colonel. This makes no difference in his regimental position; but all the colonels in the army in order of seniority become general officers. Every regiment has a colonel who is a general officer, and whose command is honorary only. These colonelcies are given to distinguished and meritorious officers, and princes of the blood-royal.

Colonnade (Fr. from Lat. *columna*). A range of columns attached to, or detached from, the body of the building they are introduced to ornament. When surrounding the building on the exterior, the colonnade is called a *peristyle*; when detached from the general line and projecting forward, it is called a *portico*; but when comprised under the same cornice as the building itself, as at the Louvre, it is called a *colonnade*.

Colony (Lat. *colonia*). Colonies are establishments formed in foreign countries by bodies of men who voluntarily emigrate from, or are forcibly sent abroad by, their mother country. Various motives have, at different periods, led to the formation of colonies. Sometimes, as in the case of most part of the ancient Greek colonies, they were formed by citizens driven from their native country by the violence of political factions; sometimes, as in the case of the Roman colonies, they were formed for the purpose of bridling subjugated provinces: the latter, indeed, were a species of camps or military stations, forming, as it were, the advanced posts of that mighty army which had its head-quarters at Rome. Sometimes, again, as in the case of the Phœnician colonies, and of most of those established in modern times, they have been formed for commercial purposes, or in the view of enriching the mother country, by opening new markets from which she might, if she chose, exclude foreigners. Most of the Greek colonies being founded by private adventurers, who received no assistance from

COLONY

the government of the parent state, were really independent; the duty which they owed to their metropolis being such only as is due to kinsmen and friends, and not that due by subjects to their rulers. The Roman colonies, on the other hand, being founded by the state for an important political purpose, were always dependent upon Rome. They formed the great bulwarks of the empire. Nor was the conquest of any province ever supposed to be completed till colonies had been established in it, and roads had rendered it accessible to the legions. The colonies established for commercial purposes have generally been subjected to such regulations as were deemed most for the advantage of the parent state. Their growth has thus in many instances been retarded; and they have been rendered less serviceable to their founders than they would have been had they been treated with greater liberality.

The very narrow limits within which this article must be compressed make it necessary that we should confine our statements to such remarks as have a more particular reference to those questions of colonial policy which are most interesting to the English reader.

The advantages supposed to result from that monopoly of a colonial trade which all modern countries possessed of dependencies have endeavoured to enforce, seem to be altogether imaginary. The ties of kindred, and the identity of language, customs, and manners, give the merchants of the mother country great advantages, and enable them, provided their goods be about as cheap as those of others, to supply the colonial markets in preference to everyone else. But all attempts to establish a monopoly in favour of the mother country, by prohibiting the importation of the produce of other nations into the colony, are necessarily either useless or prejudicial, not merely to its interests, but even to those of the mother country. If the latter can produce the articles required by the colony as cheap or cheaper than others, she will command the supply of the colonial markets, without any interference whatever; and if she cannot do this, unless by excluding the cheaper products of others, then it is plain that the goods sent to the colony can only be produced by diverting a portion of the capital and industry of the mother country into comparatively disadvantageous channels, or into businesses in which she is excelled by others: it is plain, too, that no artificial monopolies can be maintained, except in the case of small and easily guarded colonies. The British merchants have at present the supply of by far the greater part of the manufactured goods required by our North American possessions; because the goods they send to them are generally cheaper than those sent there by other parties. But were competitors capable of underselling our merchants to appear in the field, they would have very little difficulty indeed in depriving them of these markets. Cheap goods are sure to make their way through every barrier; and

COLONY

the frontier of our North American colonies is so very extensive, and the impossibility of guarding it so obvious, that the smallest saving in point of expense would occasion the clandestine introduction of prohibited goods in unlimited quantities. In such a case custom-house enactments are good for nothing. All the tyrannical regulations and sanguinary punishments of Spain and Portugal were unable to prevent their transatlantic possessions being deluged with the prohibited commodities of Britain, France, and Germany. The ability to supply it with comparatively cheap goods is the only means by which it is possible to preserve any market. It is this that secures for us at this moment the same superiority in the markets of the United States that we possessed in them when they were our dependencies; and the moment we lose this advantage we shall not merely lose their market, but, with it, the markets of *all* our colonies. Nothing, therefore, can in reality be more futile than to found colonies, or to retain them in a state of unwilling dependence, with the view of monopolising their trade. If we can undersell others, we shall command their markets without any sort of interference; and if we cannot do this, the attempt to force upon them comparatively dear goods is sure to be defeated; or if, unhappily, it should have a partial success, it would be injurious alike to the mother country and the colony.

A colony might be advantageous, and might contribute to increase the wealth of the mother country, if it yielded a greater revenue than was required for its government and defence; but this is rarely the case. Most colonies require a heavy outlay on their first foundation; and when they attain to any considerable importance, all attempts to make them contribute directly to increase the income of the mother country are very apt to excite discontent, and probably even rebellion: an unfortunate attempt of this sort led, in fact, to the American war. To obviate all chance of any such disastrous event occurring in future, we have distinctly renounced all pretensions to make our colonies contribute anything, unless it be towards defraying the expense of their local government and militia.

If a colony enjoy a natural monopoly of any product or article in extensive demand, it is supposed that, by laying a heavy duty on its exportation, a considerable advantage may be made to accrue to the mother country; but this, though sometimes, is but seldom the case. The monopoly of the opium of India affords one of the most striking instances of revenue thus obtained. Being produced more cheaply in Hindustan than anywhere else, government is able, by monopolising its culture, or rather by obliging it when produced to be sold to them at a certain price, and then selling it for exportation at a much higher price, to realise a large revenue. And it would do the same, and perhaps with better effect, if, supposing it could prevent a smuggling export trade, it left production to take its own course, and

merely taxed it when exported. The opium produced in India is mostly all sent to China, where the consumption now (1863) amounts to above 70,000 chests a year, producing a nett annual revenue of above 4,000,000*l.* sterling.

But a revenue arising from a source of this kind requires to be managed with great discretion. The duty imposed on the taxed article must never be so high as to equalise the peculiar advantages possessed by the colonists for its production, or greatly to narrow the demand for it in foreign countries. By neglecting these indispensable conditions the Dutch ruined the trade in spices from Amboyna and the Spice Islands, and we nearly destroyed the trade in cinnamon from Ceylon. The last-mentioned article might have borne an export duty of 3*d.* or 4*d.* per pound; but being loaded with an exorbitant duty of 3*s.* per pound, its exportation all but ceased, and could only be revived by the total abolition of the duty.

When a nation derives the whole or any considerable portion of any important article from abroad, it is necessarily exposed, especially when the supply comes from one or a few foreign countries, to the risk of more or less inconvenience, from an interruption of the friendly intercourse subsisting with such countries. When such important articles are furnished by a colony, their supply is said to be comparatively secure; and, in such cases, colonial possessions are supposed to be very valuable.

The cessation of the supplies of cotton has been quoted as a case in point, and it has been said that it could not have occurred had they been derived from one of our colonial possessions. But the disruption of the American Union, and the prolonged contest by which it has been followed, are events that were less probable than the assertion of colonial independence. The truth is, that the continued dependence of none, save comparatively small or unimportant colonies, can be safely reckoned upon. The independence of all great colonies is sooner or later sure to take place; and even during the period of their dependence on the mother country, so changed are the relations which now subsist between both parties, that no direct action could be brought to bear on the colony with a view towards specifying and determining particular branches of industry or production, without provoking active opposition.

In effect, a colony looked on as a source for raw materials, or as a market for manufactured goods, stands on the same footing as any foreign state, in the former case absolutely, in the latter, so, except in so far as the

to prefer the manufactures of the country in which they were born or brought up, to those with which they are less familiar. It will be seen, however, in the gradual and certain assimilation of civilised communities, that no preference can be maintained in the colonial

COLONY

market, except on the ground of comparative cheapness and efficiency.

It was long supposed that our colonies in the West Indies were peculiarly valuable from their furnishing us with a secure and abundant supply of sugar, an article now become a necessary of life, and yielding a very large revenue. We doubt, however, whether there was ever any good foundation for such an opinion; but, whatever may have been the case formerly, there is none now. Sugar is not produced in one or a few countries only; but is a staple product of almost all intertropical regions; and it is now largely produced even in the northern parts of Europe. [SUGAR.] So far, indeed, is it from being true that we are indebted to our West Indian colonies for abundant supplies of sugar, that of 9,180,980 cwt. sugar retained for home consumption in 1861, the West Indies only supplied us with 3,695,149 cwt. The residue was supplied by the Mauritius and India, and by Cuba, Java, and other foreign dependencies. So vast is the field whence supplies of sugar are now derived, that the total cessation of those from the West Indies would have a severe, but perhaps only a temporary, effect on prices.

Great stress is frequently laid on the advantage of colonies established in unoccupied countries, as affording a field for the ready and beneficial employment of the surplus or unemployed population that occasionally abounds in old settled and densely peopled countries; neither can there be a doubt that this is of very material importance. But, the settlement once fairly started, the outfall of emigration is determined by economical stimulants, and not at all by political connection. Labour, in such colonies, is always in great demand, and a regard for their own interests always disposes the colonists to give every fair facility to the immigration of labourers. Notwithstanding the advantages occasionally held out by the British government to encourage emigration to our North American colonies, the great current of emigration has always been directed to the United States; and, even of the emigrants that sail from this country for Canada, scarcely a fourth part remain in the province, but immediately leave it for the contiguous states of the Union. It is idle, therefore, to excuse the policy of attempting to retain colonies in a state of dependence on the mother country, on pretence of their affording, by virtue of this dependence, a readier outlet for poor or unemployed persons. The interest of the settlers will keep this outlet open, and will secure every real advantage that could, in this respect, be derived from the most complete imperial supervision.

It must not, however, be supposed, from anything now stated, that we regard the foundation of colonies as inexpedient; or that colonisation should be discouraged. We may as well talk of discouraging a law of nature. The real questions are, first, What should be the relation between a colon and the mother country?

second, How long should that relation continue? The first question, as has been stated, has long since been settled, our own government having abandoned all right or authority over such colonies or dependencies as are not military conquests or military outposts, and having left the settlers to manage their internal affairs at their own discretion. So complete is this self-government, that we have not interposed the veto of the crown on the revival of those Protectionist principles in our colonies which we have long since abandoned at home, even though the regulations of some colonial tariffs, those for instance of Canada and Australia, have appeared to be directed towards the universal chimæra of Protectionist theories, the greater development of domestic industry.

But the second question—one which never would have arisen but from the absolute settlement of the first—is of greater importance and keener debate. Shall we throw off a colony against its will, or before it demands independence? Which of the two parties, the mother country or the colony, is to be first consulted as to the period at which the connection is to be severed? Assuming that the advantage of dependence is wholly on the side of the colony, or is supposed to be so, what is the process by which the ultimate detachment of the colony should be effected? How shall the support be gradually withdrawn so as to accustom the colony to all those liabilities of political action which should go along with the privileges of political independence? These questions, discussed at present with no little warmth and acrimony, cannot be entered into within the limits of the present article, and the reader is referred to Mr. Merivale's work on Colonisation, and Professor Goldwin Smith's letters on 'The Empire,' for further details.

We have indeed abandoned the idea of keeping settlements in a state of pupillage, of directing their affairs from a colonial office in the mother country, and of regulating their markets with a view to the fancied advantages of a monopoly of sale. We found out that no economical benefit was derived from the system; and the political evils were manifest. For the government of a dependency by the chief of a bureau had all the disadvantages which could arise from the exercise of authority almost arbitrary. Even in a constitutional and responsible government such as that which we enjoy, the ordinary course of parliamentary supervision was not, and could not be, any efficient check to maladministration, simply because parliament can with difficulty be moved to take effectual cognisance of colonial affairs.

At the same time, it must be admitted that, even in the bygone days of the colonial theory, the British plantations possessed a far larger share of freedom than the colonies of any other country. Hence their progress, though incomparably less than it would have been had the government of the past adopted the wiser policy of the present, was immeasurably

COLONY

greater than that of the dependencies of Spain and Portugal.

Nothing, indeed, could be worse than the colonial system adopted by these two countries. Every native of the colony was studiously excluded from the functions of government or even of administration; perhaps with the view of making independence impossible, by depriving the colonial population of the faculty of political action. We know, indeed, that if this were the motive, the government was baffled; but the evil effect remained, and remains still, in the state of chronic anarchy in which those countries have almost invariably been since the overthrow of Spanish and Portuguese authority in the New World. The history of Mexico since its independence is the most striking because the most obvious example of the effect of the colonial policy followed by Spain; and the utter demoralisation of the country is attested as well by the observation of travellers as by the complaints which have led to the interference of foreign governments in the affairs of the country.

The war which issued in the independence of our American colonies seems to have decided, in so far as experience can decide anything, the question as to the commercial importance of dependencies, and the extent of regulations on the trading intercourse of the colony and the mother country. No colonies were ever reckoned half so valuable as those which afterwards formed the republic of the United States; and it was generally supposed that their emancipation would be decisive of the fate of Britain—that her sun would then set, and for ever! But have we really lost anything by that event? Has our trade, our wealth, or our power been in any degree impaired by the independence of the United States? The reverse is distinctly and completely the fact. The question whether we could have continued for any length of time to retain such rapidly growing countries in a state of dependence, or that we could have been advantageously united in a federal union with vast regions situated in another hemisphere, is a barren and unprofitable speculation. But notwithstanding the independence achieved by the founders of the union, we have continued, and must necessarily continue, to reap all the advantage we can reasonably claim as founders of this mighty empire in the wilderness. Englishmen will generally command a preference in the American markets. And while we are disengaged from the thankless, unmanageable, and expensive office of governing or defending all but boundless countries 3,000 miles distant, our intercourse with them grows with their growth; and we are as much benefited and enriched by them as we should have been had they continued in the same state of dependence as Australia or the Cape of Good Hope.

The previous remarks are not, of course, meant to apply to such dependencies as Malta or Gibraltar. These are not colonies, but naval stations, held for military or political purposes,

and retained on the understanding that they are essential to the maintenance of political relations. Their commercial value is nothing, and any attempt to argue their retention on such grounds as their importance to the mercantile interests of the country, is a piece of sophistry over and over again disproved.

Neither are the previous remarks meant to apply to the conquest and occupation of foreign countries, in the view of increasing national opulence and power. Such a conquest or occupancy is a matter of military interest only, in which too often the obstinate memory of past exploits, or the satisfaction felt at the power of inflicting injury, is all that can be quoted as compensating great concomitant evils. No sane Englishman would mourn over the loss of Cherbourg or Calais, held for centuries from the French, or regret that the principality of Aquitaine, the fruit of the victories of Edward III., was rapidly recovered to the same kingdom. It is certain that, if we are ever engaged again in a Continental war, the policy of this country will never be directed towards the permanent acquisition of any portion of European soil.

Sometimes, in order to carry on a trade with a colony, it is necessary to give its products peculiar advantages in the markets of the mother country; and consequently at the expense and to the prejudice of the consumers in the latter. No small portion of our trade with the West Indies was forced through the preference which their sugars enjoyed down to 1864 in our markets. The trade with Canada was also for a long while forced and factitious, depending as it did on the circumstance that the duties on colonial timber were very much less than the duties upon foreign timber, that is, on timber from the North of Europe. This preference was injurious both to the Canadians and to ourselves. It withdrew the energies of the former from the culture of the soil, the most advantageous pursuit to which they could be directed; and while it made us buy inferior timber at a comparatively high price, it narrowed our trade with the countries round the Baltic. Luckily, however, this preposterous policy has latterly been abandoned, and we are now permitted to buy timber, like sugar, wherever we find it cheapest and most suitable for our purposes.

Since these changes have been effected, the colonies in the West Indies and North America have lost much of their former prestige. They do not, in fact, produce a single article which we might not import as cheaply or cheaper from other countries. And as they furnish no surplus revenue, but, on the contrary, occasion a heavy expense for their security and protection, it is difficult to see what advantages they confer on us, or what injuries we should sustain by their becoming independent.

The people of Britain would do well to affect dispassionately on the state of the Canadian question. There are not, perhaps, a

COLONY

dozen men of sense in the empire who are not ready to admit that we derive no peculiar advantage from our connection with that possession, nothing to set against the heavy expense which it certainly involves; and, if so, what should be our policy in the mean time? Are we resolved to maintain an army of 10,000 or 12,000 men in Canada?—to expend, directly and indirectly, some two or three millions a year in preserving a mere nominal ascendancy in a colony? If such be our determination, it may be doubted whether we have profited much by the dear-bought experience afforded by the American war. National pride may prevent our relinquishing this costly and barren dominion; but good sense, and the most obvious views of expediency, would seem to suggest the policy of voluntarily anticipating what there is every reason to think must in the end necessarily happen, and of providing for the independence of Canada under a system of friendly and mutually beneficial relations.

As more enlarged and sounder views of the real value of colonies have been diffused, the relations between them and the mother countries have been gradually changed. Intelligent people have been long convinced of the impolicy of attempting to direct the internal affairs of distant communities placed under very different circumstances to their own, and such interference is no longer attempted. In the English colonies these matters are now left to be decided upon by their different councils and assemblies. These bodies, which correspond in some degree to the Lords and Commons of this country, consist, the first, of members that are usually in part nominated by the crown, and in part elected, and the second, of members elected by the colonists mostly under a widely extended system of suffrage. Wherever a body of this sort is established, it constitutes with the governor the parliament of the colony, and to it all matters of local interest, including the imposition of taxes, are committed. A power is, however, reserved to the crown of disallowing such acts of any colonial assembly as might encroach on its just prerogatives, or be prejudicial to the interests of the empire at large. Appeals from the colonial courts are made to the Court of the Privy Council; and all matters in regard to the contracting of treaties and alliances, naval and military regulations, and the making of peace or war, are vested exclusively in the crown. But with these exceptions, all British colonies having legislative assemblies may be said to be in most respects entirely self-governed. 'If,' says Mr. Mill, in his valuable work on Colonial Constitutions, 'the experience of the past has not enabled us to anticipate all the details of future difficulties, it has at all events furnished irresistible evidence of the instability of those principles of colonial policy which were once deemed to be the pillars of our national greatness. To retain for the longest possible period, at the smallest possible cost, with the greatest

possible advantage to ourselves, a permanent dominion over the dependencies of our empire, was once the problem which occupied the minds of British statesmen. To ripen those communities to the earliest possible maturity, social, political, and commercial—to qualify them, by all the appliances within the reach of a parent state, for present self-government and eventual independence, is now the universally admitted object and aim of our colonial policy'—(p. 69).

The maintenance of the existing relations between the colonies and the mother country, supposing neither party to take any step in the matter, depends upon a great variety of circumstances peculiar to each colony, which can neither be foreseen nor appreciated beforehand. At present all the substantial advantages of the connection appear to be on the side of the colonies; and it is difficult to see what they would gain by breaking it off. Hitherto we have kept large bodies of troops in New Zealand, Canada, and at the Cape of Good Hope, not because they were required for any imperial purpose, but that they might protect the colonists from the attacks of the natives, or from the dangers apprehended from powerful neighbours. But such a state of things should surely be put an end to. The colonies should be made acquainted with the cost as well as the advantages of self-government. They should be taught to provide that support for themselves which is now provided for them by others.

The large amount of military force kept on foot in British North America is not required for any imperial purpose, but is maintained to ward off any sudden attack on the part of the United States. But if Canada and British North America generally wish to preserve either their connection with this country or their own independence, they should make some greater efforts in either direction than they have made hitherto. It would hardly, indeed, be in our power to prevent these provinces being overrun, in the event of their being attacked by the Northern States, without greater exertions on the part of the colonists for their self-defence than any which they seem disposed to make. The advantages, if any, which we derive from our connection with British North America, are certainly not such as would justify, or warrant, our incurring any very great expense on its account. The colonists are themselves sufficiently powerful to resist any attacks on their independence; and if they decline doing this it is not worth our while to do for them what they can, but will not, do for themselves.

The real or supposed necessity of affording them efficient protection is a serious inconvenience which attaches to the possession of colonies in different and distant parts of the world. During war they cannot fail to absorb large portions of the force which may, perhaps, be required for the defence of the United Kingdom; and they may also afford vulnerable points which may be conveniently attacked by our enemies, and cannot be defended except

COLONY

at an immense expense and great risk. Our numerous colonial possessions are a consequence of our long-continued superiority at sea, and the maintenance of that superiority in all parts of the ocean is indispensable to the continuance of our present preponderance as a colonial power. But we incline to think that it would be good policy to contract rather than extend the limits of the latter. And when a colony, whether in Australasia or America, has attained to such a degree of population and power that with ordinary prudence it may be capable of maintaining its independence, it may be doubted whether it should not be declared independent. We should, supposing this to be done, continue to derive the same or greater commercial advantages from it; and it would afford, as a free state, quite as desirable an outlet for emigrants as if it were a dependency. And, supposing we were engaged in war, we should not have to provide for its defence; nor could our enemies or rivals hope to injure us by quarrelling with a people that had become independent, and which it would rather be their interest to seek to conciliate. All cases of this sort must, however, be peculiar; and what might be good policy in regard to A might be inexpedient in regard to B. But on the whole it appears sufficiently clear that numerous and widely extended colonial possessions involve very grave responsibilities, and seem more likely to become a source of weakness than of strength to the mother country.

The explanation given by Dr. Smith in the *Wealth of Nations* (book iv. cap. vii.) of the causes of the rapid growth and prosperity of colonies founded in advantageous situations, though impugned by Sismondi (*Études sur l'Économie Politique*, ii. cap. 'Colonies') and others, seems to be consistent alike with principle and historical evidence. When a colony is founded in an uninhabited or but thinly peopled district, each colonist gets a large extent of the best land; he has no rent, and but few, if any, taxes to pay; and being able to procure supplies of manufactured articles from the mother country, or one equally advanced, he applies all his energies to agriculture, which under the circumstances is most productive. The demand for labour in such colonies is very great; for the high rate of wages, combined with the cheapness of the land, speedily changes the labourers into landlords, who in their turn become the employers of fresh labourers. In consequence population and wealth advance with unusual rapidity; and in some instances, as in that of the United States, they have continued for a lengthened period to go on doubling every twenty or five-and-twenty years!

But in stating that the facility of obtaining supplies of fertile and unoccupied land is the principal cause of the rapid progress of new colonies, it is not meant to affirm that it is the only cause. An advantageous situation for the prosecution of commercial pursuits, and great

superiority in navigation, may enable a colony to advance at its outset, though without any considerable extent of territory, with even more rapidity than if it enjoyed an unlimited command of fertile land. This seems to have been the principal cause of the speedy extension of the old Greek colonies. The most famous of these, as Syracuse and Agrigentum in Sicily, Tarentum and Locri in Italy, and Ephesus and Miletus in Asia Minor, were amongst the principal emporia of the ancient world. They were all seaport towns; were founded in the most advantageous situations for carrying on an extensive commerce, and owed, in fact, their wealth and greatness mainly to trade and navigation. Owing, however, to the limited extent of their territorial acquisitions, a consequence partly of the difficulty of subduing the indigenous population, and partly of the neighbourhood of other colonies founded by rival states, their power rested on no very broad or solid foundation; so that the fall of the capital city and the annihilation of the state were all but synonymous.

The colonies founded in modern times have been placed under very different circumstances. The countries in which they were planted were either so very thinly inhabited as to be almost deserts, or they were occupied by a feeble and inferior race unable to oppose any effectual obstacle to the diffusion of the colonists; so that the latter easily spread themselves over a large extent of country, and have had in general more of an agricultural than of a commercial character. But while this has given them greater strength, it has not, after the difficulties attendant on their first establishment were got over, in any degree impeded their progress, but the contrary. The most flourishing of the ancient colonies cannot be compared in respect of rapidity of growth, magnitude and power, with the United States; and the slower progress of the Spanish and Portuguese colonies is not owing to the colonists having distributed themselves over a wide extent of country, but to the oppressive interference of the mother country with their domestic arrangements, and the vexatious restrictions laid on their intercourse with foreigners.

A very great degree of equality prevailed among the free settlers in Greek colonies; and in consequence the lands acquired by the colonists were distributed amongst them in nearly equal portions; but in modern times it is very different. Owing to the vast extent and almost desert state of the countries in which they have been principally planted, the poorest individuals have generally succeeded in acquiring slips of land; while the superior class of colonists, or those who had influence with the colonial government, or with that of the mother country, frequently succeeded in getting grants of vast tracts of land, not in the view of cultivating, but of holding them till in consequence of the increase of population in the vicinity they had acquired a considerable value.

These large reserves, by interrupting the communications between different parts of the colony, and increasing the difficulty and cost of conveyance, have frequently proved not a little injurious to its interests. "But there are various ways in which an abuse of this sort might be obviated; one of the most obvious being that grants of land should revert to the colonial exchequer unless certain improvements were effected upon it within a specified time after the grant was made. The inconvenience and check to progress consequent on the appropriation of large portions of the lands in a new colony, whether such appropriation arose from the occupancy of the settler, or from prodigal grants on the part of the home government, have been manifest in the past history of several colonies, and among these in none more markedly than in the first founding of the Swan River settlement, now known by the name of West Australia. Here, though abundant capital was exported for all the purposes of successful occupation and progressive prosperity, the evil of dispersion over the surface of the territory was so serious, that great part of the capital exported was wasted, and the prospects of the colony were ruined.

This, with many other instances of domestic mismanagement on the part of the colonists, induced Mr. Gibbon Wakefield, an economist of great practical sagacity, to urge the adoption of a plan which it was hoped would check the tendency to dispersion, and induce that state of 'cooperation'—to use Mr. Wakefield's phrase—between the elements of capital and labour, as would guarantee, all other things considered, the continuous combination of both these elements. Cooperation, according to Mr. Wakefield, is either simple or compound. The former is illustrated, he says, by the fact that where two or more persons are engaged in combining their strength in a single result, the effect of the combination is considerably more than the separate efforts of either. For instance, two men pulling simultaneously at a rope will raise a greater weight than could be raised by the added amount of the individual efforts of each. Two greyhounds hunting together will kill more hares than the joint product of each hunting by himself.

Compound cooperation is not very different from the division of labour. Here there is a common result, indeed; as, for instance, the building of a house; but each of the contributors to the result is engaged on a different process, while all the kinds of labour converge to one end. Now the existence of these kinds of cooperation is essential towards the economical progress of a community, as soon as it passes beyond the rudest state of social life; and both are needed for the development of agriculture. Yet the state of things which prevailed in colonies where squatting was permitted, or where vast tracts of land were easily procured, postponed indefinitely the prospect of any sound social or economical organisation.

Mr. Wakefield's plan, and it has been generally adopted in colonies, was to limit the expansion of the colony by treating all the territory contained within its boundaries as public property, not disposable except at a fixed price. The colonist, in short, had to buy the land which he purposed to cultivate; the fact that such a price had been given by the settlers being a practical guarantee against any subsequent departure from the principle, since the old settlers would not be disposed to admit incoming parties to occupation on better terms than those at which they had themselves obtained possession.

Some of the theoretical consequences of this practice will be adverted to under the head of RENT. One other, however, may be briefly dwelt upon here.

It is clear that the purchase money of land procurable on these terms is a distinct deduction from the settler's capital. If, for instance, a colonist emigrates with 500*l.*, and is desirous of occupying a farm of 200 acres, the regulation price of which is 200*l.*, his capital will be diminished by that amount, and by implication his power of employing labour, supposing such labour to be at hand. And it is certainly true that when, according to the old system, lands in the colonies were held by parties residing in England, such a diminution of the capital of settlers by purchase of part of such lands was a loss to the settlers and the colony.

But in the Wakefield scheme the evil was at least in part obviated. *The whole of the purchase money was expended in the transport of labour to the colony in which the sale was effected.* This in effect repaid the purchaser by rendering labour cheaper, and obviated the excessive tendency to dispersion over the soil. If it were an evil at all, and events make the evil remote or dubious, the benefits of the regulation vastly counterbalanced the inconvenience; and it may be confidently asserted, that, in the beginning at least of their history, the Australasian colonies have owed more to the adoption of the Wakefield scheme than to any other circumstance.

Mr. Wakefield's theory encountered much opposition. The objections taken to it are unimportant, and the controversy settled by the success of the theory in practice need not be revived.

Latterly, some colonial governments have instituted the system of granting lands to colonists who, paying their own passage money, have sufficient capital for cultivating such grants. Great and successful efforts in this direction have been made by the colony of Queensland. It is likely that such plans may induce the gradual and healthy occupation of these regions, though for a long time the near and superior attractions of the United States will absorb by far the largest number of the emigrating class.

Colophon (Gr. *a summit*: hence, a *finishing stroke*). In Bibliography, the postscript contained in the last sheet of an early printed

COLOPHONITE

work (before the introduction of title-pages), containing the printer's name, date, &c., is so termed.

Celephonite. A brown variety of iron-lime Garnet with a *resinous* lustre.

Celephony. Common resin or *rosin*. The non-volatile portion of crude turpentine, so named after Colophon, in Ionia, whence resin was obtained by the Greeks.

Colossal (from Gr. *κολοσσός*, a statue larger than life). In the Fine Arts, a term applied to any work of art remarkable for its extraordinary dimensions. It is, however, more applied to works in Sculpture than in the other arts. It seems probable that colossal statues had their origin from the attempt to astonish by size at a period when the science of proportion and that of imitation were in their infancy. Colossal statues of the divinities were common both in Asia and Egypt. By the description of the palace or temple attributed to Semiramis, it abounded with colossal statues, among which was one forty feet in height. In Babylon we learn from Daniel that the palaces were filled with statues of an enormous size, and in the present day the ruins of India present us with statues of extraordinary dimensions. The Egyptians surpassed the Asiatics in these gigantic monuments, considering the beautiful finish they gave to such a hard material as granite. Sesostris is said to have been the first who raised these colossal masses; the statues of himself and his wife having been thirty cubits in height. This example was imitated by his successors, as the ruins of Thebes sufficiently testify, the two Memnons being still in existence. The taste for colossal statues prevailed also among the Greeks. The statue of the Sun at Rhodes was executed by Chares, a disciple of Lysippus; and the great Phidias contributed several works of this order. The colossus at Tarentum by Lysippus was no less than forty cubits in height; and the difficulty of removing it, rather than the moderation of the conqueror, prevented Fabius carrying it off with the Hercules from the same city. Before the time of the Romans colossal statues were frequently executed in Italy. The first monument of this nature set up in Rome was one placed in the capitol by Sp. Carvilius after his victory over the Samnites. This was succeeded in after times by many others, of which those now on Monte Cavallo, said to be of Castor and Pollux, are well known to most persons. The principal Roman colossus was the figure of himself, as the Sun, set up by Nero before the Golden House, near the site of the temple of Venus at Rome; it was in bronze, the work of Zenodorus, and it, as Pliny says, it was 110 feet high, it was larger than the colossus of Rhodes. The great Roman amphitheatre known as the Colosseum is supposed to have been so called because it was built on the site or place of this figure. In modern times the largest that have been erected are those of San Carlo Borromeo, at Arona near Milan; and the bronze 'Bavaria'

COLUBER

of Schwanthaler at Munich, cast by Stiglmeier, nearly sixty feet high.

Colosseum. [*AMPHITHEATRE*.]

Colossochelys (Gr. *κολοσσός*, and *χέλυς*, a tortoise). A gigantic species of land tortoise, discovered by Messrs. Falconer and Cantley in the tertiary formations of India. This species was the largest Chelonian known to paleontologists. Its carapace measured more than twelve feet in length; and from its gigantic size it has been conjectured that the knowledge of it formed the base from which the mythical cosmogonies of the Hindus were derived.

Colestrum. The first milk after delivery.

Colour (Lat. color). In Painting, that quality of a body which affects our sensation in regard to its hue. *Local colours* are those which are natural to a particular object in a picture, and by which it is distinguished from other objects. *Neutral colours* are those in which the hue is broken by partaking of the reflected colours of the objects which surround them. *Positive colours* are those unbroken by such accidents as affect neutral colours.

Colours are divided into primary, secondary, and tertiary. The first are red, blue, and yellow; the second are orange, green, and purple; the third citrine, olive, and russet; all of which exist in a great variety of tints or hues. (Goethe's *Theory of Colours*, translated by Sir Charles Eastlake, 1840; and Field's *Chromatography*, &c. 2nd edit. 1841.)

Colours. Are the banners or flags of regiments of infantry. Each regiment has two, a royal and a regimental colour; on these are borne the devices, distinctions, badge and motto of the regiment, and its number, in gold characters. Crowned heads, princes, and field-marshal of our army are alone entitled to be saluted by lowered colours. The colours of a regiment are always saluted with the utmost respect by a guard, and it is customary for officers on the staff to salute colours when they are borne past at a review. The banners of regiments of dragoons are called *guidons*, and those of other cavalry regiments *standards*.

Colouring Matters. All nature abounds in these principles, and art has added to the number. The coloured appearance is not an inherent property of the body itself, but due to its effect upon ordinary light, which, as is well known, is composed of rays of all colours. If a body absorbs nearly all the light, it appears black. If it absorbs scarcely any, but reflects it or throws it off, it will appear white. But if the body contains any substance (pigment) that has the power of decomposing white light, its colour will depend upon which of the rays it absorbs and which it reflects. Strictly speaking, therefore, the colour of a pigment is due to light which it cannot absorb and which is reflected to the eye of an observer.

Coluber (Lat.). A Linnæan genus of serpents, including all those in which the sub-caudal scale-plates or scute are arranged in pairs. This extensive group is now subdivided into numerous subgenera.

Columba (Lat. *a pigeon*). A genus of birds which form the transition from the Passerine to the Gallinaceous orders. They fly well; live in a state of monogamy; build their nests in trees or in the crevices and fissures of rocks; and lay but few eggs at a time, generally two; their tail is composed of twelve quill-feathers: so far the Columbae resemble the Passerine birds. But their beak is vaulted; the nostrils perforated in a broad membranous space, and covered with a cartilaginous scale, which even forms a bulge at the base of the bill; the sternum is deeply and doubly notched; a dilated crop is developed from both sides of the oesophagus; the stomach is a true gizzard; and the lower larynx has only a single pair of muscles: all these important modifications of structure indicate the close affinity of the Dove tribe to the Gallinaceous birds. And it may be further remarked, that although the pigeons lay but few eggs at each brood, they breed frequently, and at short intervals. The male assists his mate in the business of incubation and rearing of the young, which are at first supported by a milky secretion prepared from the glandular coat of the crop, and regurgitated, together with the macerated grain. The Linnaean genus is subdivided into numerous but unimportant subgenera, characterised by the greater or less length of the bill, and the proportions of the feet and tail.

Columba Noachi (Noah's Dove). A small constellation formed by Halley, in the southern hemisphere, near the hinder feet of Canis Major.

Columbarium (Lat.). In Architecture, a pigeon-house or dove-cote. The arched and square-headed recesses in the walls of cemeteries, which were used to receive cinerary urns, were also called *columbaria*, from their resemblance to structures of this kind.

Columbite. This mineral is essentially a compound of columbic acid with the oxides of iron and manganese. It occurs in crystals, which are of a greyish or brownish-black colour, opaque, often iridescent, and possess a metallic lustre; and is found in granite in Bavaria, and in Massachusetts and Connecticut in North America.

Columbium. A metal discovered by Mr. Hatchett in 1801, in a mineral from Massachusetts in North America. [COLUMBIUM.] It has been found in a Swedish mineral called Tantalite, but its ores are extremely rare. It is acidifiable, and hence the peroxide has been termed *columbic acid*.

Columelliaceae (Columellia, one of the genera). An obscure natural order of shrubby or arborescent epigynous Exogens, inhabiting Mexico and Peru, and distinguished from *Jasminaceae*, to which order they have been referred, by having an adherent ovary, an epigynous disc, undivided stigma, and inferior capsule with polysperous cells. Of its true affinity little is known. Lindley places it in the Cinchonall alliance.

Colum (Lat. *columna*). In Anatomy, the

term is applied to longitudinal portions or tracts of the myelon, of which there are three in each lateral moiety, called from their situation in the upright posture of man, *anterior middle*, and *posterior columns*.

COLUMN. In Architecture, a member of an order, the section through the axis of which is usually the frustum of an elongated parabola. It is circular on every height of its plan; and consists of a base, a shaft or body, and a capital. It differs from a pilaster, which is square on the plan. The use of a column is to support an entablature in classical architecture; in mediæval architecture it is frequently made to receive the springing of the arches of the upper structure.

COLUMN. In Military language, is a formation of troops, narrow in front, and deep from front to rear; whereas in *line* they display a long front with the least possible depth.

Columnae Carnae (Lat.). In Anatomy, the fleshy prominences from the inner surface of the ventricles of the heart. Some are conical, with free apices giving attachment to the threads 'chordæ tendinæ' attached to the valves; others extend from one part of the walls of the ventricle to another, and are sometimes called *trabeculae*.

Colures (in Greek *αὐ κολουροι γραμμαι*, *imperfect figures*). In Astronomy, two imaginary great circles of the celestial sphere intersecting in the poles of the world; one passing through the equinoctial points of Aries and Libra and the pole of the equator, and the other through the solstitial points of Cancer and Capricorn, and the poles both of the ecliptic and equator. For this reason the first is called the *equinoctial*, and the second the *solstitial colure*. The name is supposed to have been given to them because a portion of these circles is always concealed from view under the horizon.

Colza, Oil of. The oil expressed from the seed of the *Brassica oleracea campestris*, a kind of cabbage. Colza oil is much used in France and Belgium for burning in lamps and other purposes.

Coma (Lat.; Gr. *κῆρυ*, *hair*). The assemblage of branches forming the head of a forest-tree. Also used to denote bracts that are empty and terminate an inflorescence, as in *Salvia Hornimum*.

COMA (Gr. *κῆρυ*). Lethargy, or unnatural drowsiness; whence the term *comatose*.

Coma Berenices (Lat. *Berenice's hair*). The fame of this lock of hair has likewise been perpetuated by the word *vernior*, *vernis*, and *varnish*, which alludes to the amber colour of the queen's beautiful tresses: 'Sir G. C. Lewis, *Astronomy of the Ancients*, p. 197). A constellation of the northern hemisphere, between the tail of the Lion and the Boötes. [CONSTELLATION.]

Comb or Combe. A measure of corn, commonly four Winchester bushels.

COMB or COOM. In the western counties of England, signifies a *small valley*. The same ancient word of Celtic derivation is used in

COMBINANT

Wales (*cwm*), and in the Alps between France and Piedmont (*combe*), in the same sense.

Combinant. According to Sylvester, a combinant is a covariant (or invariant) of two or more quantities, which possesses the additional property of remaining unaltered, a factor excepted, when the quantities are replaced by linear functions of themselves. Thus if

$$u = (a, b, c \mid x, y)^2$$

$$\text{and } u' = (a', b', c' \mid x, y)^2,$$

$$\text{then } ac' - 2bb' + ca'$$

is a combinant of u and u' , since it is merely changed into

$$(a\beta_1 - a_1\beta)^2 (ac' - 2bb' + ca'),$$

when for the coefficients in u and u' we substitute the corresponding ones in

$$a u + \beta u' \text{ and } a_1 u + \beta_1 u'.$$

(*Phil. Trans.* 1853.)

Combination. In Law, may take place for the performance of any unlawful act, and is punishable before such act is executed. But the word has been commonly used in a particular sense; viz. that of a combination among workmen to demand wages at a particular rate; which was an unlawful act prior to the 6 Geo. IV. c. 129, repealing former statutes; now explained by 22 Vict. c. 34. Workmen are now at perfect liberty to form such combinations; but penalties are enacted by the statute against such as use threats or violence towards those who refuse to join in them. The offence of administering unlawful oaths (whether preparatory to a combination among workmen, or for any other purpose) remains unaffected by the statute.

Combinations among workmen for the purpose of raising the wages of labour, and the machinery employed for that end, namely, a trades' union, governed by a body of delegates from different associated 'trades,' or by persons appointed to watch over the interests of a particular 'trade,' with the threat of a strike, the object of which is to compel more favourable terms from employers by the suspension of work undertaken, are a characteristic feature in the present relations of labour and capital.

Endeavours on the part of labourers to exact better wages from employers are historically as old as the attempts to limit the rate of wages. The first statute, purporting to check the demand of labourers for higher payment, is the Statute of Labourers, passed after the great plague of 1348, and enacting under heavy penalties that customary rates of payment only should be made; the compensation provided for the workmen being an attempt by the same legislative action to secure low fixed, or nearly fixed, prices of provisions. It is needless to say that the latter enactment was wholly nugatory, and the former nearly so, though agricultural labourers were, as might be anticipated, brought more nearly within the provisions of the statute than mechanics could be.

From this time to the final abolition of all laws restraining the price of labour, Acts were passed amending and fortifying the precautions taken by the Statute of Labourers. In general,

COMBINATION

the magistrates of each county were empowered to fix, year by year, the rates at which labourers were to be recompensed. In other words, the parties apparently most interested in maintaining a low rates of wages were entrusted with the power to determine the rate, and to exact the penalties provided by the statute. It is necessary to mention this, because those who have criticised the action of labourers in the practice of combinations, have been too apt to forget that much of this practice is retaliatory on centuries of combination on the part of employers.

But though the combination of labourers may be excused, it cannot be, we think, defended. The sole argument in favour of the practice is that commonly alleged, that capital is strong, and labour, or rather the individual labourer, weak, and that the union is a defence against the tyranny of capitalists. It is also confidently stated that wages have been advanced by the threat of strikes implied in the act of combination. But the arguments against the practice are far more numerous and far more weighty. The rate of wages is naturally determined by the coordinate and reciprocal influence of supply and demand. If the former be scanty and the latter great, wages will rise; if the reverse, wages will fall.

The purpose of combination is to enhance wages by creating an artificial scarcity. As the number of existing labourers and the existing demand cannot be controlled, the only means by which this scarcity can be effected are by making the labour less efficient, by controlling the means by which fresh labourers can be introduced into the 'trade,' or by arresting the supply at some critical period. The first of these methods is attained by regulating the way in which a labourer should work; as, for instance, by insisting that he should not carry materials, or by determining the hours of labour; the second is achieved by the regulations all but universally in force about apprenticeship; and the third by the mechanism of a strike. The last of these methods alone materially affects the condition of the capitalist; and various precautions have been taken, in general successfully, against the loss which might ensue from the stoppage (for instance) of works under contract.

The other two consequences affect the public, that is, the general purchaser or hirer of the produce derived from the joint operation of the labourer and the capitalist. They affect him by raising the cost of production.

It is plain to everyone, that the value of a sum of money, whether it be income or wages, is wholly determined by what it will procure by purchase. It is also clear that, if labour be rendered less efficient, the loss will not fall on the capitalist or employer of labour, except indirectly, but upon the person who purchases the commodity procured by labour. This is the more evident when the commodity is a matter of primary necessity, as, for instance, lodging or shelter from weather. Now, if the

COMBINATION

cost of a house be increased, as it probably is increased, fifty per cent. by the operation of a trades' union ramifying through all the artisans contributing to the building, the loss is equivalent to a gigantic tax levied on every occupier of a house or lodging through the whole country; and as house-rent represents a far higher percentage in the expenditure of the poor than in that of the rich, it falls with far greater severity on the very classes who have obtained an increase of money-payments in exchange for a diminution of purchasing power.

Again, the practice of combination discourages excellence in workmen. The tendency of a union is to classify the payment of wages. The employer may select his workmen, indeed, but the trades' union takes away the motive for greater energy, by denying that energy any larger remuneration.

Further, combination, to be just, should extend to all labourers; in other words, should effect a general rise in the price of labour. It is needless to say that a general rise in prices would leave everybody ultimately just where they were before the rise occurred, i.e. anybody would purchase less with more money. But the combination is possible only in particular trades or occupations. Hence, the fund for the payment of wages being a quantity, the class of labourers which can combine gets a larger, the class which cannot combine a less, quantity of the gross amount. The bricklayers and carpenters are enriched at the cost of the agriculturist or the sailor. And as the enhanced cost of the commodity supplied by the members of a trades' union is ordinarily a necessary of life, the uncombining labourers are mulcted anew by the increased cost of the commodity, and by the diminished power of purchase.

Lastly, the very existence of a system of combination stimulates, if it does not necessitate, the disposition to coerce those who are not inclined to take part in the union. It is almost a rule without exception, that where combinations are most general, outrages on non-unionists are most common. It is true that all combinations denounce in theory the practice of coercion or persecution on those who decline to take part in the system. But the disavowal is very different from the abandonment of the practice. Viewed as combinations are by workmen, as the means namely by which they achieve greater wages, and as the sole barrier between themselves and what they call the tyranny of capitalists, the man who stands aloof from them is not only looked upon as selfish, and wanting in *esprit de corps*, but as a traitor to his order, and as hostile to the material prosperity of his fellow-workmen. It is very hard, under such impressions of passive dislike and distrust, to check the disposition towards the manifestation of these feelings by acts of hostility and violence.

This sketch of some among the economical consequences of combination does not exhaust the subject. We shall have occasion to revert to certain further principles on the relations of

COMBINATIONS

labour and capital, when we speak of LABOUR, TRADES' UNION, and WAGES.

It is needless to say that the subject is treated of by most political economists, and the reader may be referred to almost any system of the principles of political economy for further arguments for and against the practice of combination among workmen, for the purpose of raising the money wages of labourers.

Combinations. In Algebra, are the different arrangements of a number of objects (letters) into groups of a given nature. In combinations no regard is paid to the order in which the objects are arranged in each group, whilst in variations and permutations this order is respected. The number of different combinations, m in each, of n different letters is

$$\frac{n(n-1) \dots (n-m+1)}{1 \cdot 2 \dots m}$$

Since each combination of m letters must leave a complementary one of $n-m$ letters, it follows that the above number is also equal to

$$\frac{n(n-1) \dots (m+1)}{1 \cdot 2 \dots (n-m)}$$

Thus there are

$$\frac{5 \times 4 \times 3}{1 \times 2 \times 3} = \frac{5 \times 4}{1 \times 2} = 10$$

combinations of 5 letters, whether taken in triplets or in pairs. When an unlimited supply of objects of n distinct kinds is given, and into each combination of m two or more objects of the same kind may enter, the total number of different combinations will be

$$\frac{n(n+1) \dots (n+m-1)}{1 \cdot 2 \dots m}$$

This, for instance, represents the number of homogeneous powers and products, of the m^{th} dimension, that can be formed with n letters, in other words the number of terms in a n -ary m -ic, which is the same as the number of terms in the expansion of $(a_1 + a_2 + \dots + a_n)^m$ [QUANTIC.] Thus a binary m -ic contains

$$\frac{2 \cdot 3 \dots (m+1)}{1 \cdot 2 \dots m} = m+1$$

terms; a ternary one,

$$\frac{3 \cdot 4 \dots (m+2)}{1 \cdot 2 \dots m} + \frac{(m+1)(m+2)}{1 \cdot 2};$$

a quaternary one,

$$\frac{4 \cdot 5 \dots (m+3)}{1 \cdot 2 \dots m} + \frac{(m+1)(m+2)(m+3)}{1 \cdot 2 \cdot 3};$$

and so on. A complete non-homogeneous algebraic expression of the m^{th} degree in one, two, three, &c. . . . variables contains, of course, as many terms as a binary, ternary, quaternary, &c. . . . m -ic, since it can be made homogeneous by introducing an additional variable. The above formulæ for combinations, without and with repetitions, are the ones most frequently required in practice: their demonstrations, as well as further details, will be found in any treatise on Algebra.

COMBINING PROPORTION

Combining Proportion. [EQUIVALENTS, CHEMICAL.]

Combining Volume. The volumes or spaces occupied by bodies in the gaseous or vaporous condition which combine chemically together. This volume can be determined by experiment or by calculation. If the atomic weight (combining weight) of a body be divided by its specific gravity in the gaseous state, the quotient will be its combining volume. Such quotients will of course only express the relation between the several volumes. The relation of atomic or combining volumes to each other is a simple one. One to one, one to two, and one to three are the common numbers.

Combretaceæ (Combretum, one of the genera). A natural order of shrubby or arborescent Exogens, of the Myrtal alliance, all living within the tropics. They possess astringency, and some are employed in dyeing. Some are polypetalous, some apetalous. They are especially distinguished by their convolute embryo.

Combustion (Lat. combustio, from comburo, *I set on fire*). This term is generally applied to the phenomena exhibited by burning bodies, and which depend upon the rapid union of the combustible with the oxygen of the air. The evolution of heat and light which attends this process announces intense chemical action; and we consequently find that combustion is always attended by the production of new compounds. [HEAT.]

Combustion, Spontaneous. [IGNITION.]

Comedy (Gr. κωμῳδία, perhaps from κῶμη, a village, and ᾠδή, a song, because the original rude dialogues, intermixed with singing and dancing, out of which the early Greek comedy arose, were sung by rustic actors at village festivals). A species of drama, of which the characteristics in modern usage are, that its incidents and language approach nearly to those of ordinary life; that the termination of its intrigue is happy; and that it is distinguished by greater length and greater complexity of plot from the lighter theatrical piece entitled a *farce*. The original Attic comedy was a burlesque tragedy in form, in substance a satire on individuals, and founded on political or other matters of public interest. The modern comedy is derived from the new comedy of the Greeks, of which Menander and Philemon were the principal authors, and which has been preserved to us through the Latin imitations of Plautus and Terence. [DRAMA.]

Comenic Acid. When a solution of meconic acid in water, or in dilute sulphuric acid, is long boiled, or when dry meconic acid is heated to 400°, it is converted into a modified bibasic acid, water and carbonic acid being at the same time evolved. The formula of comenic acid is $C_{12}H_2O_8 + 2H_2O$.

Comet (Gr. κωμήτης, from κῶμη, hair). The name given to a numerous class of celestial bodies belonging to the solar system.

The ancients gave the name of *comet* to every nebulous star or meteor which was observed to pass successively through different

COMET

constellations. Some of the ancient philosophers regarded comets as simple meteors, engendered in the atmosphere. In order, however, to be convinced that they occupy a far more remote situation, it is only necessary to compare simultaneous observations at very distant places on the earth. Tycho Brahe was the first who showed that their true place is in the planetary regions. Modern astronomers apply the name, notwithstanding the etymology, to bodies which have neither nebulosity nor tail; excluding, however, luminous meteors from the category. The distinctive characters of a comet are: 1st. That it possesses a proper motion round the sun; 2nd. That it traverses space in a curve more elliptical than the orbits of the planets, and generally so elongated that in the distant parts of its orbit it ceases to be visible. The proper motion distinguishes comets from those new stars which occasionally appear, and become extinguished without changing their place in the sky. The elongated form of the orbit establishes a distinction equally marked between the comets and the planets. They revolve about the sun according to regular laws, similar to those which govern the planetary motions.

Comets are only visible during the short time they are near the perihelia of their orbits. The revolution of all the planets round the sun is performed from west to east in the order of the signs; comets, on the other hand, appear to traverse the heavens in all directions indifferently. Of some 280 comets whose orbits have been determined, about one-half have their motion direct. Their orbits also intersect the ecliptic at all possible angles. Out of the whole number there are only nine whose returns to the sun in successive revolutions have been verified by observation.

These comets are the following:—

	Period. Years	Next Return
1. Encke's	3.29	1868, October.
2. De Vico's	5.46	1866, ?
3. Winnecke's	5.54	1869, June.
4. Brorsen's	5.58	1868, May.
5. Biela's	6.61	1866, January.
6. D'Arrest's	6.64	1870, October.
7. Faye's	7.44	1866, February.
8. Méchain's	13.60	1871, October.
9. Halley's	75.00	1910, ?

Sir Isaac Newton was the first who submitted the motion of a comet to calculation, and pointed out a method of determining its orbit from three of its observed positions. Halley applied Newton's method to a great number of comets, of which the positions had been observed; and on comparing the resulting elements, perceived that the comet which appeared in 1682 moved nearly in the same orbit with one which had been observed in 1607, and another which had been observed by Apian in 1563. He therefore predicted its return in 1759—a prediction verified by the fact.

COMET

The computation of a comet's return to its perihelion is a work of great difficulty and labour; for in consequence of the attractions of the larger planets, the path of the comet may be considerably changed at each revolution, and all these changes or *perturbations*, as they are called, must be computed from the theory of gravitation.

The elements of a parabolic orbit—and in consequence of the facility with which it lends itself to calculation such an orbit is generally first assigned to a comet—are as follows:—

1. The time at which it makes its nearest approach to the sun. [PERIHELION PASSAGE.]
2. The longitude of the place which it then occupies as seen from the sun.
3. The longitude of the place it occupies when passing upwards through the plane of the earth's orbit as seen from the sun. [NODE.]
4. The distance from the sun to the comet at its nearest approach. The unit generally chosen is the earth's mean distance from the sun.
5. The angle which the path of the comet makes with the plane of the ecliptic.

We must also know the direction, whether direct, like the planetary motions, or retrograde; and if the orbit after all be found to be an elliptic one, we must know the eccentricity.

Modern science has entirely exploded the notion of the destructive powers of comets. They are more passive than active; thus, Lexell's comet was entangled for some four months among the satellites of Jupiter, and only got away at last with an entirely new orbit, and yet the motion of the smallest satellite was not in the least deranged; there is also good reason for believing that we actually passed through the tail of the comet of 1861.

Encke has turned to account the voyages of these almost massless bodies into the depths of space, in enquiring whether there is in space a medium which resists motion, as it is in such bodies that a resistance of this kind would make itself felt. In the gradually diminishing period of his own comet, which is now less by two days than it was in 1789, he sees a proof of the existence of this medium. The consequences which follow from its presence in the planetary spaces are so grave, that although it is difficult to imagine the resistance offered to be *nil*, we must wait for further confirmation before it be accepted.

We have been richly favoured in the appearances of comets during the last few years. 1858 and 1861 will ever be red-letter years in the cometary calendar.

The great comet of 1858, or, as it was generally called during its visibility, the comet of Donati, was discovered by that astronomer on the 2nd of June in the constellation Leo, while it was yet distant from the earth 210,000,000 miles and more than 210,000,000 miles from the sun. Towards the end of August it was visible to the naked eye, but there was no long

deserving of mention in its appearance until about September 16, when it had arrived within one hundred and fifteen millions of miles from the earth, fifteen days prior to the perihelion passage. At this time commenced those indications of violent action upon the nucleus which afterwards riveted the attention of observers with the telescope. From the 2nd of June to the 8th of September, the earth was on the north side of the plane of the orbit; it crossed the line of nodes on the last-named date, giving an opportunity for observations on the figure of a section of the tail in a plane at right angles with the orbit, and upon other interesting features. In short, this comet is at once the most interesting and the best observed one on record, and we shall be doing our readers the best possible service by transcribing some of the conclusions arrived at by Professor Bond, whose monograph upon it is by far the most valuable contribution to cometary astronomy that we possess. In the last volume of the *Memoirs of the Royal Astronomical Society* will also be found a series of engravings of the telescopic appearance of the comet from drawings made by Warren de la Rue, Esq., F.R.S., with his Newtonian reflector of thirteen inches' aperture, the same instrument with which his well-known pictures of Saturn, Jupiter and Mars were drawn.

Professor Bond, comparing the results of all the observations, finds that the limiting surface of the head of the comet had a close resemblance to a surface generated by the revolution of a catenary on its vertical axis.

The tail was dark at its centre and branched; the right branch was brightest till the sun was reached, but between the 4th and 10th of October the left branch and envelopes became brightest. The branches were about this time distinctly separated by a conspicuous dark zone; this zone, at first narrow and dark, widened and gradually became indistinct.

Besides the dark zone, there was a much narrower dark canal with straight sides, which could be traced quite to the nucleus; it seemed as dark as the background of the sky. It inclined to the apparent right-hand of the axis of the tail, bringing it nearer to the direction of the radius vector.

The diameter of the actual solid nucleus must have been less than five hundred miles: the increase of size at the longer distances from the earth and sun, which is clearly indicated by the observations, was probably the effect of the dense haze of nebulousity surrounding it, which prevented its true limits from being seen.

On the 2nd of October, when the brightness of the head of the comet reached its maximum, it was 6,300 times brighter than on June 15th, the increase by observation exceeding that computed by the usual formula of the product of the inverse squares of the distances from the sun and earth, by thirty-three times.

One of the most important of the phenomena presented by the envelopes, was their regular succession and continuous ascent or expansion outwards from the nucleus. Seven distinct

COMET

envelopes have been recognised, and their history partially recovered.

The inner envelopes were observed to crowd upon the outer ones in a very remarkable manner. Bond suggests three theories:—

1. That the elevation-velocity may have been least in the earlier envelopes, causing them to be overtaken by their successors. On this point it is shown that the measurements present no such tendency in the initial velocities, but rather the contrary.

2. It is supposed that the intervals between successive envelopes may have been least in the earlier members of the series, so as to produce the appearance in question. But this also is opposed to the observations.

3. The remaining hypothesis, of a progressive diminution in the velocity of expansion for each envelope, is fully sustained by their measured breadths, in which a change of velocity is clearly exhibited.

The period between the elevation of the envelopes is found to have varied irregularly from four days sixteen hours, to seven days eight hours.

For a few days the surface of the envelopes was closed on the side opposite to the sun, although here and there penetrated by streams issuing into the tail principally from the cusps on either side. As it expanded, the discharge became general, but was always most considerable from the outside, thus forming the asymptotic branches below the nucleus. The curve on the side towards the sun in a completely formed envelope was very nearly circular for 60° or 80° on either side of the axis. This was originally the brightest and best defined region, but it was also the first to fade away, the material being evidently transferred to the outlines below the parallel of the nucleus, which remained in sight long after the upper portions had disappeared, and had been finally driven off into the tail. The process of dissipation furnishes a satisfactory explanation of the branches of the tail, which are simply the continuation of the old envelopes merged together and undistinguishable from each other, excepting near the nucleus. In this view the dark hollow of the axis represents the region not fully supplied from the envelopes, while they retained their closed or partially closed surfaces. In one instance, the materials of an envelope remained near the nucleus for eighteen days before they were expelled into the tail; it may hence be inferred that the particles do not at once acquire the property which subjects them to solar repulsion.

Several results of considerable importance have been arrived at from observations of the dark and bright spots observed on the envelopes; these are:—

1. A degree of permanence in the internal distribution of the substance of the envelopes retained for a long interval after their ejection from the nucleus.

2. That their diversified aspect, especially the isolation of bright masses, cannot be explained as a mere optical effect produced by the intersection or separation of streams of luminous

matter passing out continuously from the nucleus into the tail.

3. The nearly permanent direction maintained by the spots relatively to the axis of the tail, proves that there was no sensible rotation of the envelopes, excepting in a sense always preserving an unaltered aspect towards the sun.

4. That there was no sensible oscillatory motion of the nature of that seen in Halley's comet, as described by Bessel.

5. The repetition of spots and rays, and other similar peculiarities of structure in successive envelopes, in nearly the same direction, strongly indicates that the nucleus itself constantly maintained the same aspect towards the sun without sensible rotation, other than is implied in this condition, and without oscillation. This result, notwithstanding the absence of observed oscillations, implies the action of polar forces upon the nucleus in the manner suggested by Bessel in his explanation of the phenomena of Halley's comet.

An outer faint veil, or *umhüllung*, was another feature of this kind of comets. Mr. de la Rue's micrometrical measures on October 2, give the following real dimensions: Diameter of the nucleus 970 miles; breadth of first sector 6,470 miles, and its height from nucleus 4,460; height of third sector 11,980 miles; breadth of narrow channel in the tail 3,120 miles; at a distance of 255,850 miles from the outside bright head of coma, the tail was 219,300 miles broad; the centre of the dark channel was 109,650 miles from either side of coma. We may remark in conclusion that the last published (*Astronomische Nachrichten*, No. 1,524, April 27, 1865) elements of this comet assign a period of 1880 with an error of $\pm 6\frac{1}{2}$ years.

The great comet of 1861 presented a succession of eleven envelopes rising at regular intervals on every second day. Their evolutions and final dissipation were accomplished with much greater rapidity than the corresponding phenomena of the comet of 1858. Discovered in Australia in May, it made its appearance in these latitudes on the evening of June 30, when its aspect in the north-west was grand in the extreme. The nucleus was hardly inferior in brilliancy to Venus, and certainly superior to Jupiter; while the tail was traced in the country fully 90° , and in the clear atmosphere of Rome no less than 118° , from the head. The comet had passed its nearest point of approach to the earth about noon on the same day, and was then separated from us rather less than thirteen millions of miles. If, to determine the length of the tail, we compute from Professor Secchi's estimate at midnight on June 30, which assigns, for the angular extent, 118° , it will be found that the true length, assuming the principal tail to be a prolongation of the radius vector, or line joining the sun and comet, would be less than twenty millions of miles, which is by no means an unusual figure. We speak of the *principal* tail, or the long straight ray everywhere visible; but there existed, in addition to this, a secondary and

much less conspicuous train of diffused light, emanating from the nucleus in an arched form, which was more particularly noticed between June 30 and July 4, though chiefly by practised observers; and this leads us to mention a very interesting circumstance in the history of the comet. About the time of the nodal passage (June 28, evening) it was remarked that the earth was behind the comet only 2 degrees in longitude, as seen from the sun; and the latter body being the nearer to that luminary, it followed that the direction of the tail was such as to bring it either upon or very near to our globe. Accordingly it was conjectured that, with due allowance for curvature, it was quite possible the earth might have been involved in the tail on the evening of June 30, when she arrived at the comet's nodal point of longitude. Observations subsequently published, which enable us to determine the true direction of the tail with more certainty, appear to indicate that the main branch was in advance of the earth on that evening, but that the secondary tail, or the diffused nebulousity which separated from the principal ray, was actually directed upon us and was probably intermingled with our atmosphere. And it is a remarkable and significant fact, that not only in various parts of England and Ireland, but also in Spain, Italy, Switzerland and other Continental countries, a very peculiar phosphorescence or illumination of the sky was perceptible during the early hours of the night in question, which many persons supposed to be caused by the aurora borealis, unusual as the phenomenon is in the summer months, especially in the South of Europe; at the same time it was remarked that the luminosity of the sky did not resemble the usual effect of the aurora, but was something quite exceptional. We incline to attribute the phenomenon to the presence of cometic matter (if matter it can be termed) in our atmosphere.

In concluding this brief summary of the more prominent points of interest afforded by the great comets of 1858 and 1861, it may be observed that the physical phenomena they exhibited had been for the most part previously witnessed in certain conspicuous comets, and particularly in the famous comet of Halley at its last appearance, but had never been watched with such advantages of optical power and force of practised observers as in those years. Bessel's theory of opposite polarities is the only one which seems to explain them even in part, but it would be difficult to render his views intelligible to the general reader within the limits of this notice.

Cometarium. An astronomical toy, intended to represent the motion of a comet about the sun. Any instrument capable of describing an elongated ellipse may be called a *cometarium*. [ELLIPTIC COMPASSES.]

Comitia (Lat.). In Ancient History, the assemblies of the Roman people, which were of three kinds, distinguished by the epithets *Curiata*, *Centuriata*, and *Tributa*.

1. The *Comitia Curiata* were the assemblies

of the patrician houses or *populus*; and in these, before the plebeians attained political importance, was vested the supreme power of the state. The name *Curiata* was given because the people voted in *curia*, each *curia* giving a single vote representing the sentiments of the majority of the members composing it; which was the manner in which the tribes and centuries also gave their suffrages in their respective *comitia*. After the institution of the *Comitia Centuriata*, the functions of the *curiata* were nearly confined to the election of certain priests, and passing a law to confirm the dignities imposed by the people.

2. The *Comitia Centuriata* were the assemblies of the whole Roman people, including patricians, clients, and plebeians, in which they voted by centuries. By the constitution of the centuries these *comitia* were chiefly in the hands of the plebeians, and so served originally as a counterpoise to the powers of the *comitia curiata*, for which purpose they were first instituted, it is said, by the law-giver king Servius Tullius. These *comitia* quickly obtained the chief importance, and public matters of the greatest moment were transacted in them; as the elections of consuls, praetors, and censors, and the passing laws and trials for high treason.

3. The *Comitia Tributa* were the assemblies of the plebeian tribes. According to the popular tradition, they were first instituted after the expulsion of the kings; and in them were transacted matters pertaining to the plebeians alone, as the election of their tribunes and *aediles*.

Comity of Nations (Lat. *comitas*, *courtesy*). Is defined in International Law to be the usage or practice which mitigates the severity of right *stricti juris* in the intercourse between civilised nations. (Phillimore *On International Law*, part iii. ch. i.) Thus it has been a question much debated whether international comity did not require the mutual surrender of criminals: although this is now in practice provided for by extradition conventions. Or, to take the simplest case, the absolute right of a state to dismiss foreigners from its limits (called by French writers *droit du renvoi*) is mitigated by the ordinary *comity* which allows the subjects of one state to dwell peaceably in another.

Comma. In Grammar. [PUNCTUATION.]

COMMA (Gr.). In Music, a very small interval, being about the ninth part of a tone.

Command. In Fortification, the height of one work above another, or above the ground, measured from the crests of the parapets.

Commander. In the Royal Navy, is the intermediate rank between lieutenant and captain. In large vessels there is a commander as well as a captain. In sloops, and vessels of that class, the commander is the senior officer. A commander ranks with a lieutenant-colonel in the army, but as junior of that grade. His pay is 30*l.* 2*s.* 6*d.* per annum, with 15*l.* 12*s.* 6*d.* additional if in chief command.

COMMANDER-IN-CHIEF

Commander-in-Chief. The officer in whom is vested the supreme command of all the land forces of the British Empire. This officer is appointed by the sovereign, and is supposed to enjoy the confidence of the ministry. He acts in conjunction with the Secretary of State for War, and is assisted in the discharge of his duties by several subordinate officers, such as the ADJUTANT-GENERAL, the QUARTERMASTER-GENERAL, &c. (see these terms), who are each at the head of a particular department.

There is also a commander-in-chief in India, who is subject to the commander-in-chief at home.

A naval commander-in-chief is the flag officer who commands the squadron or fleet in a particular ocean-district.

Commandery or Preceptory. According to the usages of some orders of Knights, a district attached to a manor or chief-messuage under the control of a member of the order, who receives the income of that district arising from the estates of the order, taking out of it his own pension, and accounting for the rest.

Commelinaceæ (Commelina, one of the genera). A natural order of herbaceous Endogens, chiefly inhabiting the East and West Indies. They are referred to the Xyridal alliance, and characterised by three sepals opposite the carpels, three petals, six (or three) stamens, axile placentæ, and a trochlear embryo. The species, often mere weeds, are occasionally beautiful flowering plants. A common example is the *Tradescantia virginica*.

Commendam, In (Low Lat.). A term of the Canon Law. A person to whom custody of a void ecclesiastical benefice is committed by the superior, without the profits appertaining to it, was said to hold the benefice *in commendam*, i.e. *entrusted to his care*; but by various devices the restriction on the receipt of profits was evaded, and the holding benefices in commendam became a mode of enjoying pluralities. An ordinary case was where clergymen promoted to bishoprics with insufficient revenues were allowed in this manner to retain the profits of livings. Commendams have now been abolished by 6 & 7 Wm. IV. c. 77.

Commensurable (Lat. con, and mensura, a measuring). Two or more quantities of the same kind are said to be commensurable when each contains, an exact number of times, some other quantity of a like kind. Hence commensurable quantities are always proportional to certain whole numbers, and conversely all quantities are commensurable which are proportional to any series of whole numbers, or, we may add, fractions; since the latter, after reduction to a common denominator, are proportional to their numerators. In the expression of quantities by numbers, therefore, the commensurability of the former is tacitly assumed, whereas it can be shown that, *in general*, they are not so. No measure of the side of a square, for instance, however small the same may be, is contained an exact number of times in its diagonal. [INCOMMENSURABLE.] Hence arises

COMMERCE

an imperfection in the application of algebra, or arithmetic, to geometry; an imperfection which Euclid has avoided in his admirable fifth book. It is evident that the sum or difference of any multiples of two commensurable quantities must be commensurable with each; and, on the other hand, that every common measure of one of two quantities, and the sum of difference of any multiples of these quantities, must also be a measure of the second quantity.

Commentary (Lat. commentarius). In Literature, a word used in different significations: 1. In the same sense with *memoirs*, as a short narrative of particular events and occurrences, composed by an actor or spectator of those events with the professed object of calling back the circumstances to his own mind; e.g. the *Commentaries* of Cæsar. 2. Critical observations on the text or contents of a book. These are either in the form of detached notes, containing remarks on particular passages; or they are embodied in what is termed a *running commentary*, or series of remarks written and printed in a connected form.

Commerce (Lat. commercium, from con, and merx, wares or merchandise). The exchange of one sort of produce or service for some other sort of produce or service.

Exchanges of this description have their rise in the nature of man and the circumstances under which he is placed, and their origin is coeval with the formation of society. The varying powers and dispositions of different individuals dispose them to engage in preference in particular occupations; and in the end every one finds it for his advantage to confine himself wholly or principally to some one employment, and to barter or exchange such portions of his produce as exceed his own demand, for such portions of the peculiar produce of others as he is desirous to obtain and they are disposed to part with. The division and combination of employments is carried to some extent in the rudest societies, and to a very great extent in those that are most improved; commercial intercourse being developed in exact proportion to the progress of the social state. The division of employments could not exist without commerce, nor commerce without the division of employments: they mutually act and react upon each other. Every new subdivision of employments occasions a greater extension of commerce; and the latter cannot be extended without contributing to the better division and combination of the former.

In rude societies, the principal business of commerce, or the exchange of one sort of commodities for some other sort, is carried on by those who produce them. Individuals having more of any article than is required for their own use endeavour to find out others in want of it, and who at the same time possess something that they would like to have. But the difficulties and inconveniences inseparable from a commercial intercourse carried on in this way are so obvious as hardly to require being pointed out. Were there no merchants or

COMMERCE

dealers, a farmer, for example, who had a quantity of wheat or wool to dispose of, would be obliged to seek out those who wanted these commodities, and to sell them in such portions as might suit them; and having done this, he would next be forced to send to, perhaps, twenty different and distant places, before he succeeded in supplying himself with the various articles he might wish to buy. His attention would thus be perpetually diverted from the business of his farm; and while the difficulty of exchanging his own produce for that of others would prevent him from acquiring a taste for improved accommodations, it would force him to endeavour to supply such things as were essential by his own labour and that of his family; so that the division of employments would be confined within the narrowest limits. The wish to obviate such inconveniences has given rise to a distinct mercantile class. Without employing themselves in any sort of production, merchants or dealers render the greatest assistance to the producers: they collect and distribute all sorts of commodities; they buy of the farmers and manufacturers the things they have to sell; and bringing together every variety of useful and desirable articles in shops and warehouses, enable all persons, without difficulty or loss of time, to supply themselves with whatever they want. Continuity is in consequence given to all the operations of industry; for, as everyone knows beforehand where he may dispose to the best advantage of all that he has to sell, and obtain all that he wishes to buy, an uninterrupted motion is given to the plough and the loom. Satisfied that they will have no difficulty about finding merchants for their produce, agriculturists and manufacturers think only how they may improve and perfect their respective businesses. Their attention, no longer dissipated upon a variety of objects, is fixed upon one only. It becomes the object of everyone to find out machines and processes for facilitating the separate task in which he is engaged; and while the progress of invention is thus immeasurably accelerated, those who carry on particular businesses acquire that peculiar dexterity and *sleight of hand* so astonishing to those who live in places where the division of labour is but imperfectly established. Facility of exchange is, in truth, the vivifying principle, the very soul of industry; and no interruption is ever given to it without producing the most ruinous consequences.

The merchants, or dealers, collect their goods in different places in the least expensive manner; and by carrying them in large quantities at a time, they can afford to supply their customers at a cheaper rate than the latter could supply themselves. Not only, therefore, do they, by enabling every employment to be carried on without interruption, and the divisions of labour to be perfected, add prodigiously to the powers of industry, and, by consequence, to the wealth of the community, but they also promote the convenience of everyone, and re-

duce the cost of conveyance and transfer to the lowest limit. According as commerce is extended, each particular business becomes better understood, better cultivated, and carried on in the best and cheapest method: where it is far advanced, the whole society is firmly linked together; every man is indebted to every other man for a portion of his necessities, conveniences, and enjoyments; everything is mutual and reciprocal; and a large country becomes in effect, from the intimate correspondence kept up through the medium of the mercantile class, like a large city.

The mercantile class has been divided into two leading classes—the wholesale dealers and the retail dealers. This division, like the divisions in other employments, has grown out of a sense of its utility. The wholesale merchants buy the goods at first hand of the producers; but instead of disposing of them to the consumers, they generally sell them to the retailers or shopkeepers, by whom they are retailed or distributed to the public in such quantities and in such a way as is most suitable for them. The interest of all parties is consulted by this division. Had the wholesale dealers attempted also to retail their goods, they could not have given that undivided attention to any part of their business so necessary to insure its success. A retailer should be constantly at his shop; not merely that he may attend to the orders daily sent to him, but that he may learn all that may happen with respect to the situation of his customers, their wants and their circumstances. But wholesale dealers being obliged to attend to what is going on in different and distant quarters, cannot give this minute attention to what happens in their immediate vicinity; and even if they could, the capital required to carry on a wholesale business would not be sufficient for that purpose, were the business of retailing joined to it. Were there only one class of merchants, the capital and the number of persons employed in commercial undertakings would not probably be less than at present; but the merchant, being obliged to apply himself principally to one department, would have to leave the chief share of the other to servants; a change which, as every one knows, would be accompanied by the risk consequent on intrusting one's own business to others. There can, therefore, be no doubt that the separation in question has been highly advantageous. The classes of merchants, like those of artificers, are mutually serviceable to each other and to the public.

In a highly civilised country like Great Britain, the trade in every commodity in considerable demand, as corn, sugar, tea, timber, &c., affords employment for a separate class of traders. But for all purposes of general enquiry, it is sufficient to consider commerce under three heads, viz.: 1. The Home trade, or that carried on between individuals of the same country; 2. Foreign trade, or that carried on between individuals of different countries; and 3. The Colony trade, or that carried

COMMERCE

on between the inhabitants of any particular country and its colonists. We subjoin a few remarks upon each of these heads.

I. *Home Trade*.—It has been already seen that the varying capacities and dispositions of different persons occasion the introduction of a division of employments, and the practice of exchange or barter. But the external circumstances under which men are placed vary still more than their natural powers or tastes. One set inhabit a rich fertile plain, suitable for the growth of corn and other analogous crops. Another set inhabit a mountainous district, the soil of which is comparatively sterile, but which is well fitted for rearing cattle; another set are planted upon the margin of a river, or arm of the sea, abounding in every facility for carrying on the business of fishing; and so on. Now it is obvious, that though the individuals belonging to any particular district had not established a division of labour amongst themselves, it would be highly for their advantage to establish one with those occupying other districts, the productions of which are materially different. When the inhabitants of Newcastle apply themselves principally to the coal trade, those of Essex to the raising of wheat, and those of the highlands of Scotland to the raising of cattle and wool, each set avail themselves, in carrying on their employments, of the peculiar powers of production conferred by Providence on the districts they occupy; and by exchanging such portions of their produce as exceed their own consumption, for the surplus articles raised by others, their wealth and that of everyone else is immeasurably increased. It is in this territorial division of labour, as it has been happily designated by Colonel Torrens, that the main advantage of commerce consists. In commercial countries, each individual may not only enter at pleasure on such pursuits as he deems most advantageous, but the entire population of districts and provinces are enabled to turn their energies into those channels in which they are sure to receive the greatest assistance from natural powers. Suppose England were divided into separate parishes, or even counties, surrounded respectively by Bishop Berkeley's wall of brass, and having no intercourse with each other, in what a miserable situation should we be! Instead of 2,300,000, London could not under such circumstances contain 30,000 inhabitants; and these would be exposed to the danger of an interruption in the supply of the necessaries of life. Unless the territorial division of labour were carried out to some extent, the division of employments amongst inhabitants of the same district could be but very imperfectly established, and would be of comparatively little use. It is only when one is able both to gratify his taste and to avail himself of the varying capacities of production given to different districts that the benefits of commerce can be fully appreciated, and that commerce becomes the most copious source of wealth as well as the most powerful engine of civilisation.

II. *Foreign Trade*.—The trade carried on between individuals of different countries is founded on precisely the same circumstances—the differences of soil, climate, and productions—on which is founded the trade between different districts of the same country. One country like one district, is peculiarly fitted for the growth of corn; another for the cultivation of the grape; a third abounds in minerals; a fourth has inexhaustible forests. Providence, by thus distributing the various articles suitable for the accommodation and comfort of man in different countries, has evidently provided for their mutual intercourse. In this respect, indeed, foreign trade is of far more importance than the home trade. There is infinitely less difference between the products of the various districts of the most extensive country, than there is between the products of different and distant countries; and the establishment of a territorial division of labour amongst the latter must therefore be proportionally advantageous.

But to enable the advantages of foreign commerce to be rightly appreciated, it will be proper to consider it under the following heads: viz. 1. Its influence in supplying us with useful and desirable articles, of which we should otherwise be wholly destitute; 2. Its influence in multiplying and cheapening the peculiar productions of our own country; 3. Its influence in making us acquainted with foreign discoveries and inventions, and in exciting invention by means of competition and example; and, 4. Its indirect influence upon industry, by increasing the sources of enjoyment.

1. With respect to the first of these influences, or the effect of commerce in furnishing every people with commodities not otherwise attainable, it is too obvious and striking to require any lengthened illustrations. Great Britain is as abundantly supplied with native products as most countries; and yet anyone who reflects for a moment on the nature and variety of the articles we import from abroad, must be satisfied that we are indebted to trade for a very large part of our superior accommodations. Tea, sugar, coffee, wine, and spices; silk and cotton, the materials of our most extensive manufactures; gold and silver; and an endless variety of other highly important articles, are sent to us by foreigners. And were their importation put an end to, what a prodigious deduction would be made, not from our comforts and enjoyments merely, but also from our means of supporting and employing labourers! If foreign commerce did nothing more than supply us with so many new products, it would be very difficult to overrate its value and importance.

2. But such is the beneficent influence of commerce, that while it supplies an endless variety of new productions, it multiplies and cheapens those that are peculiar to every country. It does this, by enabling each separate people to employ themselves, in preference, in those departments in which they enjoy some

COMMERCE

natural or acquired advantage, and by opening the markets of the world to their productions. This principle holds universally. The most important manufacture, at least till recently, carried on in Great Britain—that of cotton—is entirely the result of commerce. Supposing, however, that cotton wool had been a native product, we could never have made such astonishing advances in the manufacture if we had been denied access to foreign markets. Notwithstanding the splendid discoveries in the machinery, and the perfection to which every department of the trade has been brought, the vast extent of the market has prevented its being glutted, and has stimulated our manufacturers and artisans to persevere with unabated ardour in the career of improvement. Our cotton mills have been constructed, not that they might supply the limited demand of Great Britain, but that they might supply the demand of the whole world. And in consequence of the extraordinary subdivision of labour, and the scope given to the employment and improvement of machinery by the unlimited extent of the market, the price of cottons has been reduced to less, probably, than a fourth part of what it would have been had they met with no outlet in foreign countries. The hardware, woollen, leather, and other manufactures, exhibit similar results. The access which their products have had to other markets has led to important improvements in their production; so that, as was previously stated, commerce not only supplies us with a vast variety of new and desirable articles, but it also cheapens the staple productions of the country, and renders them more easily attainable by the great mass of people.

3. The influence of commerce in making the people of each country acquainted with foreign inventions and discoveries, and in stimulating ingenuity by bringing them into competition with strangers, is obvious and powerful. It distributes the gifts of science and art, as well as those of nature. It is the great engine by which the blessings of civilisation are diffused throughout the world, the intercourse to which it gives rise making everyone acquainted with the processes carried on and the inventions made in the remotest corners of the globe. Were any considerable improvement made in any important art either in China or Peru, it would be very speedily understood and practised in England. It is no longer possible to monopolise an invention. The intimate communication that now exists amongst nations renders any important discovery, wherever it may be made, a common benefit. The ingenious machine invented by Mr. Whitney, of the United States, for separating cotton wool from the pod, has been quite as advantageous to us as to the Americans; and the inventions of Watt and Arkwright have added to the comforts of the inhabitants of Siberia and Brazil, as well as of England. The genuine commercial spirit is destructive of all sorts of monopolies. It enables every separate country to profit by the peculiar natural powers and

acquired skill of all the others; while, on the other hand, it communicates to them whatever advantages it may enjoy. Every nation is thus intimately associated with its neighbours. Their products, their arts, and their sciences, are reciprocally communicated; and the emulation that is thus excited and kept up forces routine to give place to invention, and inspires every people with zeal to undertake, and perseverance to overcome, the most formidable tasks. It is not possible to form any accurate notions as to what would have been our state at this moment, had we been confined within our own little world, and deprived of all intercourse with foreigners. We know, however, that the most important arts, such as printing, glass-making, paper-making, &c., have been imported from abroad. No doubt we *might* have invented some of these ourselves; but there is not the shadow of a ground for supposing that we should have invented them all; and without foreign example and competition, we could hardly have carried any of them beyond the merest rudiments.

4. The influence of commerce upon industry, by its increasing the number of desirable articles, though not quite so obvious, perhaps, as the influences already specified, is not less powerful and salutary. Industry is in no respect different from the other virtues, and it were idle to expect it should be strongly manifested where it does not bring along with it a corresponding reward. In the early stages of society, before artificial wants have been introduced, and men are satisfied if they can avert the attacks of hunger, and procure an inadequate defence against the cold, industry is confined within the narrowest limits; and if the mildness of the climate renders clothing and lodging of little importance, and the earth spontaneously pours forth an abundant supply of fruits, the inhabitants are immersed in sloth, and seem to place their highest enjoyment in being free from occupation. Sir William Temple, Mr. Hume, and some other sagacious enquirers into the progress of society, have been struck with this circumstance, and have justly remarked that those nations which have laboured under the greatest national disadvantages have made the most rapid advances in industry.

But in civilised and commercial societies, new products and new modes of enjoyment, brought from abroad, or invented at home, stimulate the inhabitants to continued exertions. Their acquired tastes and the wants which civilisation introduces, and custom and example render universal, become infinitely more numerous, and as urgent as the tastes or wants of those that are less advanced. The passion for luxuries, conveniences, and enjoyments, when once excited, becomes quite illimitable. The gratification of one desire leads immediately to the formation of another. Hence the true way to render a people industrious is to endeavour to inspire them with a taste for the luxuries and enjoyments of civilised

COMMERCE

life; and this will be always most easily done by giving every facility to the cultivation of foreign commerce. The number of new articles, or, in other words, of new motives to stimulate, and new products with which to reward the patient hand of industry, is then prodigiously augmented. The home producers exert themselves to increase their supplies of disposable articles, that they may exchange them for those of other countries and climates; and the merchant, finding a ready demand for such articles, is stimulated to import a greater variety, to find out cheaper markets, and by anticipating wants to supply incentives to the industry of consumers. Every power of the mind and body is thus called into action; and the passion for foreign commodities—a passion which some shallow moralists have ignorantly censured—becomes one of the most efficient causes of industry, wealth, and civilisation.

III. *Colony Trade*.—For some remarks on this head, the reader is referred to the article COLONY.

Principle and Influence of Restrictions on Commerce.—The commercial intercourse carried on between the inhabitants of different districts of the same country, and those of different countries, is founded on the principle which prompts each member of the same family, or each inhabitant of the same village, to apply himself to some one business. It would therefore seem that that *freedom* of commerce which is universally admitted to be productive of the most beneficial consequences when established between the occupants of different districts of the same country, must be equally beneficial when established between those of different countries. It appears to be generally believed, that to occasion a commercial intercourse, nothing more is necessary than to remove such legal or physical obstacles as may interpose to prevent it. But this is not by any means enough. A of Yorkshire does not sell to or buy from B of Kent, merely because there is nothing to hinder him from doing so; he must further believe that his interest will be promoted by the transaction: unless he do this, the utmost facility of exchanging will be offered to him in vain; nor will the finest roads or the speediest conveyances occasion the least intercourse. We neither buy nor sell for the mere pleasure of the thing. We do so only when we believe it will be a means of promoting some end, of procuring some peculiar advantage for ourselves that we could not so easily procure in any other way. If anyone supposed he could better attain his object in entering upon a commercial transaction with some particular individual by entering upon a similar transaction with some one else, or by any other means, he would most certainly decline engaging in it. We may, and often do, make a false estimate of what is for our advantage; but its promotion is the mainspring of our actions; and it is this, and this only, that we have in view when we buy of

a particular individual, or resort to a particular market, in preference to others.

Unless, therefore, it could be satisfactorily established that princes and rulers understand better than their subjects what has a tendency to promote the wealth and industry of the latter, it is difficult to see on what ground any restriction on the freedom of commerce is to be vindicated. The person who buys French wine or Polish corn, does so only that he may benefit himself; and the fair presumption is that he does what is right. Human reason is, no doubt, limited and fallible; we are often swayed by prejudice, and are apt to be deceived by appearances. Still, however, it is certain that the desire to promote our own purposes contributes far more than anything else to render us clear-sighted and sagacious. 'Nul sentiment dans l'homme,' says M. Say, 'ne tient son intelligence éveillée autant que l'intérêt personnel. Il donne de l'esprit aux plus simples.' The principle that individuals are, speaking generally, the best judges of what is most beneficial for themselves, is universally admitted to be the only one that can be safely acted upon. No writer of authority has lately ventured to maintain the exploded and untenable doctrine, that governments may advantageously interfere to regulate the pursuits of their subjects. It is their duty to preserve order, to prevent one from injuring another; to maintain, in short, the equal rights and privileges of all. But it is not possible for them to go one step farther, without receding from the principle of non-interference, and laying themselves open to the charge of acting partially by some, and unjustly by others.

'The statesman,' says Adam Smith, 'who should attempt to direct private people in what manner they ought to employ their capitals, would not only load himself with a most unnecessary attention, but assume an authority which could safely be trusted not only to no single person, but to no council or senate whatever, and which would nowhere be so dangerous as in the hands of a man who had folly and presumption enough to fancy himself fit to exercise it.' (*Wealth of Nations* p. 200.)

In every discussion as to any point of public economy, it is essential to bear in mind that the legislature abandons its duty, or rather acts in direct opposition to it, the moment it begins to legislate in the view of promoting the interest of particular classes. The question never ought to be whether any proposed measure or regulation has a tendency to benefit agriculturists, manufacturers, or merchants; but whether its tendency be to benefit the public. Certain individuals or classes may be benefited by what is prejudicial to others; but it would be a contradiction to contend that a system of policy which enriches A by impoverishing B can be publicly advantageous; and it is upon this latter consideration that the attention of the legislature should always be

COMMERCE

fixed. Whatever has any tendency to increase the security of property, to perfect the divisions of labour, to stimulate industry and ingenuity, and to increase the wealth and comforts of *all* classes, deserves the encouragement of government. But when it goes farther, and interferes to prohibit individuals from carrying on certain branches of trade that others may be promoted, it arrogates to itself that authority the assumption of which is so justly censured by Adam Smith. Such prohibition is, in fact, quite subversive of the right of private property; for that right is violated, not merely when a man is unjustly deprived of any part of his fortune, but also when he is prevented from disposing of it in any way, not hurtful to others, he may think fit. We may safely leave the conduct of individuals to be determined by their own prudence and sagacity. They act under the most serious responsibility; and we have the best attainable security, the plain and obvious interest of the parties, that they will, in the peculiar circumstances under which they are placed, follow that course which is most advantageous for themselves, or, in other words, for the community.

We cannot, however, feel any surprise that these principles should have been so widely departed from, and that commerce, and indeed most sorts of industry, should have been everywhere subjected to restrictions and regulations. These restrictive laws originated in a comparatively unenlightened age, before the genuine sources of public wealth and the limits of proper interference on the part of governments had been explored and defined. The fallacies on which most of them are founded, however obvious they may now seem, were not speedily or easily detected; and, after their hollowness has been exposed, the return to a better system is a work of extreme difficulty. Every regulation affecting the employment of capital and industry, though always injurious to the public, is, for the most part, productive of advantage to a greater or smaller number of individuals. The moment that any change is proposed, these persons lay before government the most exaggerated representations of the injury that would result from the abolition or modification of the regulation; and not satisfied with this, they most commonly enlist a portion of the press into their service, and availing themselves of all the aid that sophistry and ingenuity can supply, labour to make the public believe that the regulation complained of is a national benefit, and that they are interested in its support! This device has very often been attended with the most complete success; and it is to this circumstance, more than to anything else, that the tenacity with which erroneous theories in commerce are supported is to be ascribed, and that sophisms, after having been again and again exposed, are put forward anew with as much seeming confidence as if they had never been questioned.

The measure of the commerce of this country is supplied by the returns of the declared value

of all exports and imports. We have annexed to the foot of this article an account of the annual value of such commodities from January 1858 to the end of September 1864.

For a long time it was imagined that the test of a nation's commercial prosperity was to be found in the excess of the export value of its trade. This fancy, part of the mercantile theory exploded by Adam Smith, was derived from the notion, that in countries which did not produce the precious metals, or which did not produce them in any quantity commensurate with the wants of the country, the necessary supply could only be effected by a permanent excess in the value of exports. For the causes which regulate the distribution of the precious metals, in so far as they are used as a measure of value, the reader is referred to the article MONEY. At present it is sufficient to say, that there is no article of commerce which is so little affected by any statutory regulation as the precious metals. In the worst ages of legislative interference with the freedom of commerce, traders in these commodities were easily able to avoid any prohibition of the export of gold and silver; and at the present time the distribution of these products is governed by laws which fulfil the conditions of scientific exactness with absolute regularity; every country holding just as much of the precious metals as it needs for the purposes of trade, and no more.

The difference between the value of exports and imports (some elements, as the cost of transit and the variation in the rate of exchange, being taken into account) represents, as far as 'declared real values' can represent a value, the profit of the trade. The exports of a country pay for its imports, and the schedules of the two are as exact a statement of the commerce of the country, on the hypothesis that the returns can be relied on, as the 'profit and loss' account of a trading company indicates the available assets for dividend to shareholders. If, therefore, the real value of the exports equalled or exceeded that of the imports, the business would be carried on at a loss.

One caution, however, should be given in the interpretation of these returns, and this quite independently of their presumed exactness. They do not (as they are assumed to do) indicate any necessary connection between magnitude on the one side and *general* prosperity on the other. It is too commonly the case that politicians call attention to the growth of this commercial balance-sheet of the nation as designating great national wealth. But no small part of the increase may be assigned, first, to the great growth of English shipping; and next, to the fact that, by being the first to set her tariffs and mercantile system on a sound and sensible basis, Great Britain is becoming more and more a universal entrepôt for produce; in other words, an open market for all nations.

COMMERCE

Real Value of the Total Imports and Exports of Merchandise, distinguishing British, Foreign and Colonial Produce (000's omitted).

	1858	1859	1860	1861	1862	1863	1864 First 8 Months
Imports :	£	£	£	£	£	£	
Foreign . . .	125,969	139,708	167,571	164,809	160,434	164,235	
Colonial . . .	38,615	39,474	42,960	52,676	65,283	84,684	
Total . . .	164,584	179,182	210,531	217,485	225,717	248,919	176,265
Exports :							First 9 Months
Great Britain and Ireland . . .	116,609	130,412	135,891	125,103	123,992	146,602	
Foreign and Colonial	23,174	26,281	28,630	34,530	42,176	50,300	123,404
Total . . .	139,783	156,693	164,521	159,633	166,168	196,902	

The above Table does not include Exports and Imports of Gold and Silver Bullion and Coin.

Commissariat (Fr.). That department of an army whose duties consist in supplying provisions, forage, camp equipage, &c. to the troops. Every army on active service has its own commissariat, under a commissary-general. Abroad, our commissariat officers act as military accountants.

Commissary (Fr. commissaire). Is used in various ways as nearly synonymous with *deputy*. In the Army, the officers of the commissariat department are styled *commissaries*. In Ecclesiastical Law, an officer of the bishop intrusted with the performance of duties in the bishop's absence or in remote parts of the diocese is so called.

Commission (Lat. commissio). In the Army. The warrant authorising an officer to exercise command in the army is called his *commission*. Commissions in the Artillery and Engineers are given in the first instance to cadets from Woolwich [CADET], and in the higher ranks by seniority without purchase. In the Guards and Line commissions are given with or without purchase, as vacancies occur by an officer's selling out or by death. Until lately the sovereign signed all commissions; but an Act was passed a short time ago dispensing with the royal signature. The prices of commissions appear in the *Army List*.

Commission. In Law. An appointment, usually by warrant or letters patent to one or more as commissioners, to perform certain duties specified in the instrument. In this mode many of the highest judicial or ministerial functionaries of the realm are appointed; thus, the judges of the superior courts hold several commissions, as of oyer and terminer, gaol delivery, &c. High offices of state, when not regularly filled, are often intrusted to commissioners for the time being, and said to be put in commission; thus the custody of the great seal is put in commission in the absence of a lord chancellor and lord keeper. The Treasury and Admiralty have of late times been usually intrusted to commissioners, no lord high treasurer or lord high admiral having been appointed. The Court of High

Commission consisted of persons appointed under letters patent to examine into matters of ecclesiastical jurisdiction, under stat. 1 Eliz. c. 1 (abolished 16 Ch. I.). Magistrates or justices of the peace are appointed by means of a commission, occasionally renewed, commonly termed the *commission of the peace*.

Commission. In the Navy. The title of the appointment or warrant of officers of the rank of lieutenant and above to hold their office. The commission is signed by the lords commissioners of the Admiralty.

Commissure (Lat.). A term applied in Anatomy to certain parts of the brain which cross from one of its sides to the other. [BRAIN.]

Commissure. In Botany, this term signifies the place of junction of two opposite carpels.

Commitment (from Lat. committo). In Law, the sending to prison of one charged with any crime. It appears to have been the ancient usage that whoever could lawfully arrest a person for felony or treason could also send or bring him to the common gaol; but since the Habeas Corpus Act it is the uniform practice that offenders are committed by the warrant in writing of a justice of the peace. The privy council and secretary of state can also commit in cases of treason. A commitment in writing must declare the authority of him who makes it, and also the nature of the offence with which the party is charged.

Committee. In the language of Parliament, is either a committee of certain members, or a committee of the whole house. [PARLIAMENT.] *Select committees* are bodies appointed by open nomination or by a peculiar mode of election for the transaction of business, either according to the standing orders, by Act of Parliament, as in the case of election committees, or by accustomed usage. All private bills are referred in the first instance to select committees. *Joint committees* in former times consisted of bodies deputed by the two houses, which met for the purpose of adjusting differences, sometimes after free conferences had failed. They were free from the forms observed in conferences.

COMMODORE

As in the latter, the Lords deputed only half the number of members sent by the Commons. They have been long disused.

Commodore (Port. *commendador*, a *commander*). The senior captain of a squadron, when there is no admiral present.

Common (Lat. *communis*). In Law, is the right which one person has of taking a part of the produce of land, while the whole property in the land is vested in another. Common of pasture is either, 1. *Common appendant*, which is the right of the tenant of a manor to pasture his beasts on the lord's waste; 2. *Common appurtenant*, annexed to land by grant or prescription; 3. *Common in gross*, a right severed from the land.

When a common is under pasture, all those who have a right of pasturage may turn out on it a certain number of animals, according to the extent of the enclosed grounds which they cultivate. When the common consists wholly or partly of arable land, this arable land is formed into ridges, generally with a narrow riband or balk of turf between each ridge, or between each two or three ridges. The right of cultivating these ridges is distributed among the holders of the enclosed lands of the parish, according to the extent of their possessions; and in order that there may be no partiality, and that everyone may have as much interest in preserving his neighbour's ridge as his own, the ridges which any individual has the right of cultivating do not lie together, but are distributed among the ridges of his neighbours. Enclosure of commons is usually effected by local Acts of Parliament; regulated, however, by the provisions of the General Enclosure Acts 41 Geo. III. c. 109, and 8 & 9 Vict. c. 118, &c.

Common Measure. In Mathematics, a quantity which is contained an exact number of times in each of two or more given quantities. [COMMENSURABLE.]

Common Pleas or Common Bench, Court of. In Law, was originally that branch or side of the *aula regia* in which civil causes between subjects were tried. It was separated and rendered stationary, while that portion of the court from which the King's Bench is derived followed the person of the king by a provision of Magna Charta. This court has concurrent jurisdiction with the other two superior common law courts [COURTS, SUPERIOR] in personal actions and ejectments. But it retains exclusive jurisdiction over all other mixed, and all real actions or pleas of land. These, however, have now nearly fallen into disuse. [PLEADING.] The Court of Common Pleas has one chief and four puisné judges.

Common Prayer Book. The name given to the collection of all the offices of regular and occasional worship according to the forms of the church of England. The basis of this book is to be found in the King's Primer, set forth in 1546 by Henry VIII., which was intended to convey instruction to the people in the most important parts of the church service; but contained little more than the Creed, Lord's

COMMONWEALTH OF ENGLAND

Prayer, Commandments, and Litany. This Primer underwent two revisions and republications under Edward VI., whose second Liturgy approaches very near in its contents to that which exists at present. It was at that review that the Sentences, Exhortation, Confession, and Absolution were prefixed to the Daily Service; the Decalogue was introduced into the Communion Service; and certain remnants of the Romish customs were finally abolished, as the sign of the cross in confirmation and matrimony, the anointing of the sick, and the prayers for the dead.

On the accession of Elizabeth, another review of the Liturgy was instituted; but the alterations effected were little more than in the selection of the Lessons. At the review in the reign of James I., after the conference with the Presbyterians at Hampton Court, no change of importance was introduced, except the addition of the explanation of the Sacraments in the Catechism. Again, when on the restoration of Charles II. a conference had been held with the Dissenters at the Savoy, the subject of the Common Prayer Book was reconsidered in convocation. The services for the 30th of January and 29th of May were then added, as also the Form to be used at Sea. A few trifling alterations were made also in the other services; but these were the last that have been effected. On the accession of William III. another revision took place, and a considerable number of alterations were proposed and supported by many of the bishops and clergy; but they were rejected by convocation, and have never since been revived by authority. The following is a chronological list of the revisions of the Prayer Book in which any alterations have taken place:—

1546. The King's Primer.

1548. The Communion Service.

1549. First Liturgy of Edward VI.

1550. First Ordination Service.

1552. Second Liturgy of Edward VI.

1552. Second Ordination Service.

1560. Liturgy of Elizabeth.

1604. Alterations introduced by James I.

1633. Alterations introduced by Charles I.

1661. Last Revision; authorised Liturgy.

Lastly, the occasional or political services have been recently abolished by Act of Parliament.

Common Salt. [ROCK SALT.]

Common Time. In Music, that in which every measure or bar contains an even number of subdivisions, such, for example, as two minims, four crotchets, eight quavers, and so on.

Commons, House of. [PARLIAMENT.]

Commonwealth. [REPUBLIC.]

Commonwealth of England. In History, the form of government established in England on the death of Charles I. in 1649, and which existed during the protectorate of Oliver Cromwell and his son Richard, until the abdication of the latter in 1659. The substitution of a democratical for a monarchical form of government was provided for and

enjoined by two successive charters. The first charter of the commonwealth was drawn up, in December 1653, by the *council of officers*, who, on the voluntary resignation of the parliament in the early part of the same year, had declared Cromwell 'Protector;' it was styled the 'Instrument of Government.' The second charter, called the 'Petition and Advice,' was framed, in May 1657, by the parliament which the Protector had assembled in the previous year. Under the first charter, as has been well observed, the English government may be classed among republics with a chief magistrate at its head; under the second, it became substantially a monarchy, and Oliver Cromwell from 1657 to the period of his death was de facto king of England. On the demise of Cromwell, the succession of his son Richard was at first cordially recognised; but soon afterwards discontents and cabals having sprung up in the country, his inability or disinclination to govern induced him to abandon the protectorship after eight months; and on the 29th of May, 1659, the restoration of the monarchy under the old régime was effected by the triumphal entry into London of Charles II. For the character of Cromwell's government and foreign policy, see Hallam's *Constitutional History*, chap. x.

Communion, Holy. In Ecclesiastical History, a name given to the sacrament of the Eucharist, from the language of St. Paul, 1 Cor. x. 16.

Communism. [RIGHT OF PROPERTY and SAINT SIMONIANS.]

Commutants (Lat. *commuto*, *I exchange*). Functions which include determinants, but are less general than permutants. Their formation will be best illustrated by an example. Let (123), (132) &c. be symbols of any quantities whatever, and take any group of three rows of indices, such as

1,2,3,4,
1,2,3,4,
1,2,3,4.

Permute the indices of all the rows except the first, in all possible ways, and from each of the new groups thus obtained, such as

1,2,3,4,
3,2,1,4,
2,4,3,1,

form the product of the symbols (132), (224), (313), (441) corresponding to the columns; prefixing, in each case, the sign compounded of the signs (+, -) due to the row-arrangements of each group [RULES OF SIGNS]; the algebraical sum of all such products - (132)(224)(313)(441) will be the commutant, which may be said, in this example, to be of the fourth order and second class. A symbol for such a commutant would be

$$\left\{ \begin{array}{c} 1234 \\ 1234 \\ 1234 \end{array} \right\},$$

and a commutant of the first class would be clearly a determinant. [DETERMINANT.]

We may add that a commutant of the n^{th} order and m^{th} class consists, in general, of n sum of $(-)^m$ terms, each term being a product

of n factors or constituents. Thus in the above example, we should have $(1 \times 2 \times 3 \times 4)^4 = 576$ terms, each consisting of four factors. Further details on commutants will be found in papers by Cayley and Sylvester published in the *Cambridge and Dublin Mathematical Journal*.

Commutation. In Astronomy, the angle of commutation of a planet is the angle formed at the earth by a straight line drawn from the earth to the sun, and the orthographical projection on the plane of the ecliptic of the straight line which joins the earth with the planet. It is measured by the difference between the sun's longitude and the geocentric longitude of the planet.

Commutation of Tithes. [TITHES.]

Comose. Ending in a tuft or kind of brush.

Companion. The head or covering over a ladder (or staircase) in a ship; but the name is commonly applied to the ladder itself.

Company (Fr. *compagnie*). In its most general sense, this word means any two or more individuals associated for any common object whether of business or pleasure.

In its more limited sense, however, and that in which it is usually understood in this country, the term *company* means an association of individuals for the prosecution of some industrial undertaking. Such associations may be of very various descriptions, inasmuch as the terms of the association or partnership may be varied in an infinity of ways. Generally, however, they may be said to be either *private* or *public* companies; i.e. companies with a small definite number of partners, and with a large or indefinite number; and public companies may further be divided into *joint-stock* and *regulated* companies, and these again into *incorporated* and *unincorporated* companies, or into companies without and with the *unlimited liability* of the partners. [JOINT-STOCK COMPANIES.]

1. The principle on which associations for industrial purposes are established is too obvious to require much illustration. All great results are brought about by cooperation, and could not be effected otherwise. Isolated man is comparatively feeble and helpless; the capacity of associating for a common purpose is, in fact, the main source of his power and the principal distinction between him and the lower animals. One man has capital without skill, and another skill without capital; if such persons act independently, they will be able to effect little or nothing; but if they combine their efforts, and the capital of the one be applied and directed by the skill of the other, the effect of their exertions will be incomparably greater. But this is not all. Many of the greatest and most important works undertaken in modern times could not have been attempted by one individual, how opulent or skilful soever. It is to the voluntary association of individuals, for the purpose of commercial profit, that we owe those stupendous creations of modern art and science, which far exceed the most re-

COMPANY

nowned works of the wealthiest princes of antiquity. These great partnerships, only possible where property is secured by the just and equal administration of law, are characteristic of modern civilisation. They were virtually unknown to the economy of Greece and Rome, for the associations entered into in these communities seldom negotiated anything beyond the collection of taxes. The principle, however, on which companies are formed, can be traced to the action of the Italian merchants during the later part of what are called the middle ages, and in these to the formation of joint-stock banking companies.

In our own country they commence with the trading companies of merchant adventurers, created out of the stimulus given to trade by the simultaneous discovery of the New World and the Cape passage, and the diversion of traffic from the trading towns of Italy, by the adoption of long sea-voyages. Since this epoch, one of these companies has founded and consolidated a vast empire, while another has exercised a delegated sovereignty over the greater part of the North American continent. Or, to advert to agencies of more unquestionable public utility, we owe to the joint-stock principle the banks, the roads, the canals, the railways, and other similar gigantic undertakings, which, by receiving and aggregating small fragments of capital, have rendered such vast services to the industrial energies of mankind. Nevertheless, great as have been hitherto the effects of this principle, we shall find, in all probability, that they are comparatively speaking as nothing by the side of results to be hereafter achieved by the extension and adaptation of voluntary associations for trading purposes.

II. In *private* companies the business is usually conducted by one or more of the partners on the principles laid down in the deed of partnership. The rights and obligations of the partners as respects each other are, of course, mainly determined by this deed: as respects the public, the law regards the act of one partner as the act of the company: and each partner is bound, without any regard to the sum he has subscribed to the company's stock, to the whole extent of his fortune, for the debts and engagements of the firm. Certain formalities are necessary at the withdrawal of a partner; such as advertising in the *Gazette*, and the sending of special information of the fact to all individuals in the habit of dealing with the company. [PARTNERSHIP.]

III. *Public* companies may, as already stated, be either joint-stock or regulated; and these again may be either incorporated or unincorporated.

1. By a joint-stock company is meant a company the stock of which is subscribed by a certain number of persons in shares of a certain amount. Thus, supposing that a joint-stock association is to be formed for carrying on the business of banking or insurance, for excavating

a dock or a canal, or for constructing a railway, and that its capital is to amount to 1,000,000*l.* to be subscribed in shares of 100*l.* each; any individual (unless exceptions be made in the conditions under which the company is to be formed) who can command 100*l.* may become a partner of this association, and will be registered in the company's books as the holder of a share of 100*l.* of the company's stock. It is customary, too, in the vast majority of instances, to allow individuals to transfer their stock or shares to others, who succeed to all the rights and obligations of their predecessors; though in some cases the vendor's liability is continued for a considerable time after he has transferred his shares or stock. The price which shares or portions of stock fetch in the market depends, of course, on the real or supposed state of the company's affairs: if it be known or supposed to be in a flourishing and prosperous condition, and paying a high interest or dividend on its stock, the latter may sell for 10, 20, 50, or 100 per cent. or upwards of advance; whereas if it be known or supposed to be in an unprosperous condition, its shares may not bring a third or a tenth-part of what they originally cost.

The affairs of companies of this description are usually conducted by salaried officers, who are appointed by and act under the orders of a board of directors chosen by the company at large, according to the conditions in their deed of association. The partners in such companies are all individually liable, without regard to the magnitude of their stock or shares, for the entire debts and obligations of the company.

At common law no action can be raised by or against such companies without making all the shareholders parties to the action. But the obvious and insuperable inconveniences that would result from the enforcement of this rule led to the enactment, 1 Vict. cap. 73, that the crown may at pleasure grant to joint-stock associations letters patent, authorising them to sue and be sued in the names of particular officers of their own: without, however, unless government judge proper, incorporating the company, or affecting the liability of the different partners for its debts.

2. When joint-stock companies are incorporated by royal charter, or by letters patent, the liability of the partners is limited to the amount of their stock, and they cease to be responsible beyond that amount. This is the case with some great joint-stock associations (as the banks of England, Scotland, and Ireland), and many of the insurance companies. In the earliest of these joint-stock companies the privileges granted by charter were obtained in consideration of large sums of money paid to government, or lent at low rates of interest. This was particularly the case with the Bank of England.

The grand distinction between unincorporated and incorporated joint-stock companies is, that in the case of the former the law looks only to the individuals forming the association, while in the case of the latter it looks only to the association itself.

COMPANY

in the latter it looks only to the corporate body, and pays no attention to the individuals of which it is made up. On judgment against an incorporation, execution can only pass on the corporate property; and supposing it to become insolvent, the partners can only, as already stated, be called upon to make good the amount of the stock of the incorporation standing in their names. But it is quite otherwise with an unincorporated joint-stock company: should it become insolvent, the partners, to use the words of Lord Eldon, are severally liable for the whole debts and engagements of the company, even 'to their last shilling and their last acre.'

3. *Companies with limited liability.* Latterly, however, it has been deemed of importance to lessen this unlimited responsibility now referred to, and very great facilities have in consequence been given for the formation of companies on the principle of *limited liability*. They may now be introduced into most of the industrial departments; and various statutes have been passed defining the proceedings necessary to be followed in constituting companies so as to insure the limitation of the liabilities of the partners. These companies have many points in common with what the French call *sociétés en commandite*, in which the *gérant*, or manager, is alone responsible to the extent of his means, the other partners, or *commanditaires*, being responsible only for the amount of their shares.

Great difference of opinion has prevailed as to the prudence of permitting the formation of such companies. The principle, however, has been so far approved by public opinion, as to make the question practically unimportant, though it may be well to say a few words as to the grounds of objection taken, and to the arguments in favour of the system.

The chief objection to the principle of limited liability is, that it encourages fraud by diminishing responsibility. It is held that, when the liability is absolute, there is a great check to rash and *protected* speculation. And it has been alleged, with some show of reason, that the fact of joint-stock banks declining, with very few exceptions, to avail themselves of the power of rendering their shareholders liable for the amount of their shares only, is a conclusive proof that the principle is unsound; because these trading companies, whose reputation cannot be trifled with or suspected, are averse to the protection which they can assume.

But, on the other hand, it is answered that partners may find it advantageous to trade on unlimited liability, without it being at all necessary that efficient guarantees should be taken for the soundness of their operations. In point of fact, the worst cases of commercial fraud are those in which the dictum of Lord Eldon, quoted above, has applied in theory but failed in practice, because the acre and the shilling have been pledged and spent before the crash occurs. Nay, we may go farther, and say that the principle of unlimited liability may, in banking operations at least, produce what is practically an imperial guarantee. It

is possible to conceive a bank, whose subscribed capital is large, but whose liabilities on deposit and on commercial bills may be many times over the amount of its capital. The management of such a bank may be generally excellent, and the supervision exercised by its directors unwearying. But it may, even though not injured by any fraud, become the object of a commercial panic, and if its liabilities were, as has been suggested, great, even if its assets be based on excellent securities, it may be so affected as to require some strong external support for its preservation during a crisis, and in order to avoid a great national disaster, procure aid from government. And it may be alleged that, if its liability were limited, its business would be safer because more circumscribed.

In point of fact, all joint-stock companies share the weakness more or less inherent in business concerns where the manager has only a slight share in the profits of the undertaking. Such delegated management would be at all times and naturally less cautious, less anxious, more speculative, more unthrifty, than a business which formed the sole interest of an individual. To determine whether unlimited or limited liability is the safer for the public or the shareholders is not perhaps at present possible, but the trial which has been given to the system is by no means unfavourable to the principle, and in no way justifies the forebodings which have been uttered as to the risks attending limited liability.

It has been urged that the same privilege should be extended to private partnerships; and as public opinion is decidedly favourable to the system, it will not probably be long before it will be accepted to this extent. There does not, indeed, seem any great difference between a loan from a capitalist to a trader, and an advance made by a banker to a beginner; and there is a suspicion that the opponents of the principle of limited liability are not so much influenced by anxiety for the public, as by a desire to check a practice which might enter into serious competition with the interests of ordinary traders.

3. *Regulated companies* consist of a number of unconnected individuals or associations engaged in the same business or department of trade, under condition of their conforming to regulations laid down for their common guidance. Such companies have been mostly formed for the prosecution of the trade with distant and peculiarly situated countries. Their principle is not to exclude individual competition, but merely to make the different parties engaged in the trade observe the same general rules. Companies of this description were at one time common; but they have now mostly fallen into desuetude, though it is easy to imagine circumstances in which they might be advantageously revived.

4. *Civic companies*, of which there are many in the city of London and other large towns, are in reality *guilds* or *fraternities*. Originally

they consisted of the parties carrying on a peculiar trade or profession; and in most instances they gradually acquired the privilege of prescribing the conditions and limitations under which individuals not belonging to the fraternity might obtain leave to engage in its peculiar trade within the precincts of the city or borough to which it belonged. In more modern times, however, the injurious influence of such restrictions on the free exercise of industry became obvious; and in consequence the powers formerly exercised by civic companies or guilds over individuals not free of their society, who attempted to carry on the same trade, have been either wholly repealed or greatly modified. At present, therefore, the companies in question exist principally as charitable institutions, or as incorporated associations, having, in many instances, the management of large amounts of property appropriated for the use of their poorer brethren, or for some similar purpose.

COMPANY. In the Army, a body of men, forming one of the chief divisions of a battalion of infantry. The establishment of company is generally about 100, but it varies according to the requirements of the service, as determined at the War Office. A company is commanded by a captain, and has two subaltern officers attached to it.

Comparative Grammar. [GRAMMAR LANGUAGE.]

Comparison or Simile. In Rhetoric appears to differ from METAPHOR [which see], only in form: the resemblance being stated in the first case, while it is implied in the second. This is the sense in which the term *comparison* is used and defined by Aristotle, in his *Art of Rhetoric*. Frequently the same idea furnishes at the same time both comparison and metaphor; as in the following line, 'They melted from the field as snow.' The word *melted* is used by transferring the property of the snow to a multitude of individuals: so far, therefore, the phrase is a metaphor; but the additional words 'as snow,' transform it into a direct comparison. It will generally be found that in every language the earliest writers, especially the poets, are the most addicted to the use of comparisons and metaphors of a highly figurative and bold character, as is especially observable with respect to the poetry of the Old Testament, and to Homer; while as language advances in cultivation the metaphor comes more and more into ordinary use, and forms, as it were, the basis of composition, while at the same time it gradually loses the energetic and poetical cast which at first distinguished it.

Comparison, Degrees of. In Grammar. Inflections of adjectives denoting the degree in which a quality is possessed by a substance, either generally or in reference to other substances. Although some systems of Grammar speak of three degrees of comparison, there are in strictness only two, the comparative and the superlative, of which the former compares two conceptions only, as 'John is taller than Charles.' The second compares one conception

with any number of others, whether as denoting definite or general superiority.

Compass (Fr. *compas*, a word made up from Lat. *con*, and *passus*, a step). A name given to instruments contrived to indicate the magnetic meridian, or the position of objects with respect to that meridian. According to the purposes to which the instrument is chiefly applied, it becomes the *mariner's compass*, the *azimuth compass*, the *variation compass*, each particular application requiring some peculiarity of construction; but whatever modifications it may receive, the essential parts are the same in all cases. These are a magnetised bar of steel, called the *needle*, having (fitted to it at its centre) a cap, which is supported on an upright pivot, made sharp at the point in order to diminish the friction as much as possible and allow the needle to turn with the slightest force. The *mariner's compass* has a circular card attached to its needle, which turns with it, and on the circumference of which are marked the degrees, and also the 32 points or *rhumbs*, likewise divided into half and quarter points. The pivot rises from the centre of the bottom of a circular box, called the *compass box*, which contains the needle and its card, and which is covered with a glass top to prevent the needle from being disturbed by the agitation of the air. The compass box is suspended within a large box, by means of two concentric brass circles or gimbals; the outer one being fixed by horizontal pivots, both to the inner circle which carries the compass box, and also to the outer box, the two sets of axes being at right angles to each other. By means of this arrangement the inner circle, with the compass box, needle, and card, always retains a horizontal position notwithstanding the rolling of the ship.

The notation of the mariner's compass is as follows: The circumference being divided into the four quadrants by two diameters at right angles, the extremities of these diameters are the four cardinal points (*cardo, a hinge*), marked N., S., E., W. (north, south, east, west). Bisecting each of the quadrants, the several points of

bisection are denoted by placing the two letters at the extremities of the quadrant in juxtaposition. Thus, N.E. (north-east) denotes the point which is half-way between north and east; and so with N.W., S.E., S.W. (north-west, south-east, south-west). Let the octants

next be bisected; the points of division are denoted by prefixing to each of the above combinations first the one, and then the other of the two cardinal points of which it is formed. Thus N.E. gives N.N.E. and E.N.E. (north north-east, and east north-east); and so in respect of the others. Sixteen points have thus been named. Let the distances be again bisected; then each of the points so found is expressed by that one of the preceding points already named to which it is nearest, followed by the name of the cardinal point towards which its departure from the nearest points leads it, the two being separated by the letter *b* (by). Thus, the point half-way between N. and N.N.E. is N. by E. (north by east); that which is half-way between N.N.E. and N.E. is N.E. by N. (north-east by north), &c. The whole of the thirty-two points are thus distinguished, as in the figure.

The introduction of iron ships, and especially of iron-plated ships, has rendered the task of steering very difficult; for such vessels are themselves magnets, and the disturbance which they produce on the needle has required all the skill of our scientific men to overcome them. It has been found that the disturbance is least when the ship has been built with her head south and plated with her head north; thus the magnetism acquired during building is gradually diminished by the hammering attending the operation of plating. Frequent alterations of the first adjustments made are, however, necessary. For the process of adjustment, see *SWINGING*.

Like many other of the most valuable arts of life, the origin of the compass is entirely unknown. By some writers it is ascribed to Flavio Gioja, who lived in the thirteenth century; yet Guyot de Provence, who lived a century earlier, speaks of the loadstone, to which he gives the name of *marinetti*, or mariner's stone, as useful to navigation. The term *bussola* in Italian, and *boussole* in French, has also been supposed to be derived from our term *box*. It appears very probable that the Chinese were acquainted with the directive property of the loadstone at an early period. Their method is to place it on a small piece of cork and set it to float on water. The art of communicating the magnetic virtue to steel, and suspending the needle on a pivot, is undoubtedly a European invention.

The *crimuth compass*, being intended to show the bearing of objects in respect of the magnetic meridian, has its circle divided merely into degrees, instead of the rhumbs used in navigation, and is provided with sights to allow the angles to be taken more accurately.

The *variation compass* is designed to exhibit the diurnal changes in the deviation of the magnetic from the true meridian; and the needle is generally made of much greater length than in the mariner's compass, in order to render minute variations more sensible. [MAGNETISM.]

Compass of the Voice. In Physiology, is the number of notes of the musical scale comprehended in the voice of a singer; it usually extends from two to three octaves.

Compensation Pendulum. [PENDULUM.]

Compitalia (Lat. from *compitum*, a street). A Roman feast celebrated in honour of the Lares and Penates. Under Tarquinius Superbus, it is said that human victims were sacrificed at this solemnity. The gods invoked at it were termed *compitales*, as presiding over the streets.

Complement. In Mathematics, the complement of any magnitude is a second magnitude which, added to the first, gives a sum equal to a given third magnitude. This third magnitude is purely arbitrary and conventional. Thus the complement of an angle is its defect from a right angle. The complement of a common logarithm is its defect from 10; thus—

comp. log $2 \div 10 = 30103 - 9.69897$.

The arithmetical complement of a number is its defect from the next higher power of 10; thus—

ar. comp. $873 = 1000 - 873 = 127$.

Euclid uses the term in a somewhat different sense in his theorems on parallelograms. A parallelogram being divided into four parallelograms by drawing parallels to its sides through any point of one of its diagonals, i.e. two parallelograms which are not traversed by this diagonal are said to be the *complements* of the two which are.

COMPLEMENT OF A SHIP. Is the established number of officers and seamen of the several grades by whom she is intended to be manned.

Complementary Colours. In Optics, two colours are said to be complementary to each other, when they are such that the blending together of the two gives rise to the perception of whiteness. Thus the red and green colours of the prismatic spectrum give, when blended together, white light, as do also blue and orange.

Complex Numbers. [INTEGER.]

Compluvium (Lat.). In ancient Architecture, this word is applied to the area in the centre of Roman houses, so constructed that it might receive the waters from the roofs.

Composing (Lat. *compono*, I place together). In Printing, that branch of the art which consists in taking the types from the cases, and setting them up in such an order as to fit them for the press. The instrument in which they are set up and adjusted is called a *composing stick*, and the workman who arranges them a *compositor*. [PRINTING.]

Compositæ (Lat.). In Botany, the largest of all known natural groups of plants; and so called because the old botanists who invented the name regarded the flower-heads as compound flowers. They answer to the *Syngenesia Polygamia* of Linnaeus, and are positively characterised by having capitate flowers, syngenesious anthers, and an inferior ovary with a single erect ovule. Lindley calls the order *Asteraceæ*, and computes the number of genera as exceeding

COMPOSITE NUMBER

1,000, and of the species as over 9,000. They exist all over the world where vegetation can develop, and are sometimes trees, although more generally herbaceous plants or shrubs. Among medical species, the chamomile, wormwood, southernwood, elecampane, and opium lettuce are conspicuous; of esculents, the order contains the artichoke, the Jerusalem artichoke, the lettuce, succory, and endive; and among ornamental plants, the aster, dahlia, coreopsis, sunflower, &c. But by far the greater part of this large assemblage consists of species which are either weeds or of no known use. [ASTROLOGÆ.]

Composite Number. A number which possesses one or more divisors besides unity and itself. Composite and prime numbers are opposed to each other in this respect.

Composite Order. This order of Architecture, as its name implies, is composed of two others, the Corinthian and the Ionic. Its capital

is a vase with two tiers of acanthus leaves, like the Corinthian; but, instead of stalks, the shoots appear small, and adhere to the vase, bending round towards the middle of the face of the capital; the vase is terminated by a fillet, over which is an astragal crowned by an ovolo. The volutes roll themselves over the ovolo, to meet the tops of the upper row of leaves, whereon they seem to rest.

The corners of the abacus are supported by an acanthus leaf bent upwards; and the abacus itself resembles that of the Corinthian capital. [CAPITAL.] In detail, the Composite is richer than the Corinthian, but it is less light and delicate in its proportions. Its architrave has only two fasciæ, and the cornice varies from the Corinthian in having double modillions. The column is ten diameters high. The principal ancient examples of this order are the temple of Bacchus at Rome, the arch of Septimius Severus, that of the Goldsmiths and that of Titus, and the baths of Diocletian. The example here given is from the arch of Titus. [ORDERS.]

Composition. In the Fine Arts, that combination of the several parts, by which a subject is agreeably presented to the mind, each part being subordinate to the whole. [INVENTION.]

Composition. In Law, an agreement made between the owner of lands and the parson, with the consent of the ordinary and the patron, that such lands shall be discharged from the payment of tithes, by reason of some land or

COMPOUND INTEREST

other real recompense given to the parson in satisfaction thereof. Such an agreement, since the 13 Eliz. c. 10, is not good for a longer term than three lives or twenty-one years. *Composition* signifies also the agreement between an insolvent person and his creditors for the partial satisfaction of their claims, which in some cases prevents the necessity of administering the debtor's estate in bankruptcy.

Composition. In Music, the art of disposing and arranging musical sounds into airs, songs, &c., either in one or more parts, for voices or instruments or both. Zarlino defines it to be the art of joining and combining concords and discords, which are the matter of music.

Composition of Forces or Motion. In Mechanics, signifies combining or uniting several forces or motions, and determining the result of the whole. If a body is solicited by two forces which act in the same direction, the *resulting force*, or *resultant*, is equal to the sum of both; that is to say, the effect produced is the same as would be produced by a single force acting in the same direction, and equal to their sum. If the two forces act in opposite directions, the resultant is equal to their difference, and the body will move in the direction of the greater. If the lines of direction of the two forces make an angle with each other, the resultant will be a mean force in an intermediate direction. Thus, if the two forces be represented in intensity and direction by the two sides of a parallelogram, then the resultant is represented in intensity and direction by the diagonal of the parallelogram which passes through the angle formed by those two sides.

Composition and Resolution. [FORCES AND ROTATIONS.]

Composer. [COMPOSING; PRINTING.]

Compost. In Agriculture, manure in which the dung of animals, or other organic matter, is mixed largely with earth, mould, lime, and other inorganic substances.

Compostella Hyacinth. Crystals of Quartz found at Compostella, and coloured red by an admixture of ferruginous clay.

Compostella. St. James of, or St. James of the Sword. An ancient order of knighthood in Spain, the chief of the four military orders (Compostella, Calatrava, Alcántara, Manresa); probably founded either by Alphonso IX. of Castile (1158, 1214), or Ferdinand II. of Leon (1157, 1188). It originally began from the voluntary association of certain gentlemen to defend the great road leading to the celebrated shrine of St. James at Compostella. Pope Alexander III. gave the order its rules of government. The order possessed at one period eighty-four commanderies, with two cities and numerous burghs and villages. The knights take the vows of poverty, obedience, and conjugal chastity; to which they add a fourth, 'to defend and maintain the immaculate conception of the Holy Mother of Jesus Christ.'

Compound Interest. Interest charged not only on the principal, but also on the

interest forborne. Thus, if money is invested so that the interest is not paid as it becomes due, but successively added to the capital, the capital is said to accumulate at compound interest. [INTEREST.]

Compressibility. The quality of bodies in virtue of which they can be reduced to small dimensions. All bodies, in consequence of the porosity of matter, are compressible though liquids resist compression with immense force.

Compressor. In Artillery, a compressor is used in the service of heavy guns to check their recoil. It consists of an arrangement either for bolting down the rear of the carriage to the slide on which it recoils, or for jamming blocks attached to the carriage between the sides of the platform on which the carriage rests.

Comptonite. A variety of Thomsonite found in the lavas of Vesuvius, and named after Lord Compton.

Compurgation (from Lat. *compurgari purify*). An ancient mode of trial both in civil and criminal cases. In the latter, by the old English law (which William the Conqueror confirmed in this respect, at least as to its features), the accused party was allowed to clear himself by the oath of as many of his neighbours to his innocence as amounted in collective worth, according to the legal arithmetic of the Anglo-Saxons to one pound (*Warrand*), if he could in the first instance (being a villein) obtain the testimony of his lord that he had not been previously convicted. If otherwise, he was bound to undergo ordeal, or wage his law with a greater number of compurgators. Compurgation in criminal cases was abolished in general by Henry II.'s assizes, the ordeal being enforced in lieu of it. But it was retained as a special franchise in some boroughs, to which those assizes did not extend; and the last instances of it on record are to be found in the rolls of the hundred court of Winchelsea, in the reign of Henry VI. (Sir F. Palgrave *On the British Commonwealth*.) A singular usage of the same description long remained in the ecclesiastical courts, by which convicted clerks, allowed their clergy and delivered up to the ordinary, were admitted to purge themselves by the oaths of compurgators; it was abolished by 18 Eliz. c. 7. Wager of law, in civil cases, lay in some personal actions only, and in incidental traverses in real actions. (Blackstone, lib. iii. c. xxiii.) It is now abolished.

Corns, Cocons, Coconses or Chives. The points of the radicles of malted grain, which after kiln-drying drop off during the process of turning. They are sold by maltsters under the name of *malt dust*, and are considered excellent manure.

Con Sordini (Ital.). In Music, a direction to perform the passage, if on a pianoforte, with the dampers down, or on a violin with the mute on; it is usually written short, C.S.

Connere. A form of peasant occupancy once common in Ireland, though now rapidly

becoming extinct. It consisted in the part or whole payment of wages by small grants of land, and closely resembled the allotment system prevalent in the times of the old poor law. It was worse, because even more precarious, than the cottier system, and it contributed with it to the social and economical degradation of the Irish peasantry. Experience generally seems to show, that unless the possession of land is extensive enough to supply subsistence at least to the occupier, and is durable enough to stimulate something more than a mere *annua cultura*, the possession of land by labourers is rather mischievous than beneficial.

Conarite (Gr. *advapos*, an evergreen thorn-tree). A greenish mineral found in small grains and crystals at Röttis in Voigtland.

Conarium (Gr. *kónos*, Lat. *conus*, a cone). A vascular membranous pyramidal sac continued from the third ventricle of the brain; the base expanding from between the anterior interspace of the optic lobes, and the apex directed forwards, and attached to the roof of the cranium.

Concave and Convex. A curve is said to be *concave* at a given point when the lines joining the latter to adjacent points fall between the spectator and the curve, and *convex* when the contrary takes place, that is to say when the curve is interposed between the spectator and the small chords in question. A surface is said to be *concave* or *convex* at any point, when the plane sections through that point and the spectator's eye are all concave or convex; when

of these sections present their concavity and others their convexity to the spectator, the surface is sometimes said to be *concavo-convex*. This is the case with the hyperboloid of one sheet or with a common dice-box. A mathematical test for concavity and convexity is easily found. When at a point on a curve the centre of curvature and the point of view fall on the same side of the tangent we have *concavity*, when on opposite sides *convexity*.

Concept (Lat. *conceptus*, part. of *concipio*, *conceive*). In Logic, a term used to signify the result of the act or process of conception or mental representation, as distinguished from the process. [CONCEPTION.]

Conceptacle (Lat. *conceptaculum*, a receiver). A name applied to the capsular fruits of many cryptogamous plants. Thus it is given to a second form of fruit which occurs the rose-coloured seaweeds distinct from tetrasperms; to certain organs in fungi containing both spores and their accessories; to the bodies which contain the reproductive organs of certain *Marsileaceae*; and sometimes even to the cases containing the spores of ferns.

Conception (Lat. *conceptio*). In Mental Philosophy, that act of the mind by which we combine a number of individuals together by means of some mark or character common to them all. We may observe, for instance, that equilateral, isosceles and scalene triangles

CONCEPTUALISM

all agree in one respect, that of having three sides: and from this perceived similitude we form the conception *triangle*.

Conceptualism. In the scholastic philosophy of the middle ages, the system which allowed the real existence of universals, but only as ideas conceived by the mind. This was the system of Abelard, as distinguished from the nominalism of Roscelin (who denied the existence of any universals except as words or propositions) and the realism of the Greek philosophers. (Hallam's *Literary History* part i. ch. iii.; Milman's *Latin Christianity* book viii. ch. v.)

Concertante (Ital.). In Music, a term expressive of those parts of a musical composition that are especially prominent throughout the piece, as distinguished from those that play only in accompaniment or subordinate parts.

Concerted Piece. In Music. A piece wherein several solo voices or instruments take prominent parts.

Concertina. In Music, a modern instrument, of the free-reed species, invented by Professor Wheatstone. It has several octaves of compass, with a perfect scale, but is very portable, being carried in the hands, which work the bellows, while at the same time the fingers act upon small keys, to admit the wind to the several reeds. It is capable of considerable expression, and has become very popular.

Concerto (Ital.). In Music, a piece composed for a particular instrument, such as the pianoforte, violin, clarinet, &c., which bears the chief part in it, and is usually accompanied by the full band.

Concetti (Ital.; rendered by English writers on rhetoric *concepts*). Ingenious thoughts or turns of expression, points, jeux d'esprit, &c. in serious composition. In the sixteenth century, the taste for this species of brilliancy, often false and always dangerous, spread rapidly in the poetical composition of European nations, especially in Spain and Italy; where the name of *concetti* was applied rather in a good than a bad sense, the critical taste being much perverted. Tasso is not free from *concetti*. After his time they became offensively prominent in Italian poetry for a century afterwards; Marino and Filicaja offer strong examples. In France, the mode of *concetti* was equally prevalent in the seventeenth century, and was peculiarly in vogue with the fair critics of the Hôtel Rambouillet, so well known by Molière's *Précieuses Ridicules*. In England, Donne and Cowley are instances of a style full of *concetti*.

Conchifera (Lat. *concha*, a shell, and *fero*, I carry). A name applied by Lamarck, Schweigger, and Latreille to all molluscs which are protected by a bivalve shell. [LAMELLIBRANCHIATES and BRACHIOPODA.]

Conchoid (Gr. *κωνχοειδής*). The name given to a curve invented by Nicomedes for the solution of the two famous geometrical problems of antiquity—the *duplication of the cube* and the *trisection of an angle*. It is constructed as follows:—

CONCHOLOGY

Let P be a given point through which any straight line is drawn to cut or meet another straight line CD given in position; if segments AB, AB' of a given length λ be taken on each side of CD, the points B, B' will trace the conchoid.

Taking P as pole and the perpendicular ($=a$) on CD as axis, the polar equation of the conchoid is clearly

$$(r \pm \lambda) \cos \theta = a;$$

in rectangular coordinates, the equation therefore is

$$n^2 x^2 = (a - x)^2 (x^2 + y^2).$$

The curve, consequently, is of the fourth order and sixth class, having a double point at the origin. [CONJUGATE POINT.] The line CD is an asymptote; meeting the curve in four consecutive points at infinity.

Conchoidal. A term used in Mineralogy to denote that the fractured surface of a mineral exhibits curved concavities, more or less deep, and bearing a resemblance to the valve of a shell. Many of the brittle minerals, as Flint, Rock Crystal, Sulphur, Anthracite, &c., exhibit this appearance in a very perfect manner.

Conchology (Gr. *κὀγχη*, a shell, and *λόγος*). The science of shells: that department of Malacology which treats of the nature, formation, physiological relations, and classification of the hard parts or skeletons of the molluscous animals.

As Osteology, inasmuch as it relates to the nature, development, and physiological subserviences of the skeletons of the vertebrate animals, is a science in the strict acceptation of the term, so also is Conchology under the like applications; but as no naturalist has yet conceived a classification of vertebrate skeletons independently of the softer organs of the body which they support and protect, and as, notwithstanding that the complex internal skeletons of the Vertebrates are closely related to their general structure and habits, the classification of these parts would not in all cases tally with the natural arrangement of the animals to which they belonged, a classification of shells merely, apart from a consideration of the molluscous animals by which they are secreted, must be still less scientific. For shells, instead of consisting, like bones, of living organised substance permeated by blood-vessels, absorbents, and nerves, are mere inorganic laminated, concretionary, or crystalline deposits of alcaresous earth, more or less combined with huminous matter: they are also formed in the skin, and are appendages to the dermal system, which in all classes of animals is the principal seat of variety. In many cases, therefore, there exists very little correspondence between the structure or even the presence of a shell and the general character of the organisation of a mollusc; and the absence of uniformity between the condition of the shell in closely allied species is exemplified in the

CONCHOLOGY

highest as well as the lowest classes of the molluscous sub-kingdom. The argonaut, the poulp (*Octopus*), the calamary, the cuttle-fish, and the spirula, all possess the same peculiar and highly developed organisation; and in a classification founded on general structure, and expressive of the true affinities of its objects, they must rank in the same order of their class. But the shells of these molluscs present respectively the following conditions: the first, a simple external, light, elastic, subtransparent, but calcareous discoidal univalve; the second, two internal, friable, subtransparent styles, composed of hardened albumen; the third, an elongated, feather-shaped, horny plate; the fourth, an internal, compressed, oval, laminated, friable, calcareous mass; the fifth, an elongated, cylindrical, conical shell, twisted spirally in the same plane, divided into chambers by calcareous partitions, perforated by a siphon, and partly internal, partly external, in its situation. Now, in a system of Conchology, understood as the classification of shells in the abstract, these productions would necessarily be dispersed into five widely different groups; and in like manner, the small, thin, and flat plate, which is buried in the substance of the mantle of the slug, would be far removed from the large external spiral shell of the snail.

But no conchologist groups together his shells strictly and exclusively according to their resemblances. All the testaceous productions of the Cephalopods, now that the real affinities of these molluscs are known, are arranged in the same group, notwithstanding their striking discrepancies of texture and form and of relative size and position as related to the bodies of their fabricators: so likewise with the shells or their rudiments of the air-breathing Gastropods, or of the Pteropodous Mollusca. In short, every purely conchological system must undergo modifications corresponding with the progress which is made in the knowledge of the true natural affinities of the molluscous animals; and the progress of Conchology is therefore essentially connected with that of MALACOZOÖLOGY, under which term an outline of the most approved classification of the Mollusca and their shells will be found.

Under the present head will be briefly treated those points which relate to Conchology as a science; viz. the developement, structure, constitution, and physiological subserviencies of

growth of the shell depends upon the deposition of fresh layers to the inner surface of the circumference of those previously formed; beyond which the new-formed layers extend in proportions which determine the figure of the future shell.

Sometimes the calcifying margin of the mantle extends outwards at an obtuse or right angle to the last-formed margin of the shell; and after having deposited a calcareous plate in this position, is retracted and absorbed, to be again similarly produced and extended after ordinary growth has proceeded to a certain extent. It is to this periodical growth of the mantle and the plethoric condition of the calcifying vessels that the ridges on the exterior of the shell in the *Venus plicata* among Bivalves, and in the *Scalaria pretiosa* among Univalves, are due. Should the mantle, instead of being uniformly extended, send outwards a number of detached tentaculiform calcifying processes, these will form a row of spines corresponding in length and thickness to the soft parts on which they are moulded; and as the calcifying processes continue to deposit shelly material during the progress of their absorption, the spines, which were at first hollow, thus become solidified, and are soldered to the margin of the shell. This developement of calcifying processes or filaments of the mantle and spines may likewise alternate with periods of the ordinary formation of the shell; and thus the exterior of the shell may become bristled with rows of spines, as in some species of *Spondylus*, and in the *Murex crassispina*.

The most simple form of shell is the cone, which may be much depressed, as in the genus *Umbrella*; or extremely elevated and contracted, as in the *Dentalium*; or of more ordinary proportions, as in the limpets (*Patella*). The apex of the cone is oblique and excentric; directed towards the head in the limpets, the argonaut, and the nautilus, but in most other molluscs towards the opposite extremity of the body. A shell may consist of one piece, as in the Inopercular Univalves; or of two pieces, as in the Opercular Univalves and most Bivalves; or of three pieces, as in *Terebratula*; or of four or more pieces, as in some of the *Pholades* and the Multivalves proper, or Chitons. With respect to the operculum, this part is sometimes calcareous, but it consists frequently of albuminous membrane only, or is horny; thus presenting the condition which the univalve shell itself presents in certain genera, as *Aplysia*, *Loligo*, &c.

The conical univalve shell is generally spirally convoluted; sometimes, as in the *Nautilus* (fig. 3), in the same plane, more usually in an oblique direction, as in figs. 1 and 2. As a general rule, the spiral univalve, if viewed in the position in which its inhabitant would carry it if it were moving forwards from the observer, is twisted from the apex downwards, from left to right, the spire being directed obliquely towards the right (a, fig. 1, indicates the spiral turns of *Pleurotoma*). In certain genera, as *Clausilia*, *Physa*, the shell is twisted

CONCHOLOGY

in the opposite direction; such snells are called *perstus* or *sinistral*. Some species of *Bulimus*,

Parula, and *Pupa* are sinistral; and a few marine shells, as *Fusus reversus*, also exhibit the reverse of the ordinary disposition of the spire.

The part around which the spiral cone is wound is termed the *columella*. This is sometimes simple, sometimes plicated, as in the *Voluta musica* (fig. 2); it is also sometimes solid,

sometimes hollow: when the latter, its aperture is termed the *umbilicus* (f, fig. 1). The opening forming the base of the spiral univalve is bounded by an inner lip *d*, and an outer lip *e*. The inner lip offers a smooth convex surface, over which the foot or locomotive disc of the mollusc glides to reach the ground.

In many Univalves, the aperture of the shell is entire; in others it is broken by a notch, or perforated by one or more holes; or a portion of it is produced into a canal or siphon (c, fig. 1); or it may present a pallial notch (b, fig. 1) opposite to the siphon. These modifications are important, on account of the constancy of their relation to certain conditions of the respiratory organs: thus the conchologist, in grouping together all the spiral univalve shells of which a part of the margin was either notched or produced into a grooved siphon, would really indicate a very natural tribe of Mollusca, every species of which he might be assured was aquatic and marine, and breathed by means of two gills having a pectinated structure, to which the water is conducted by a fleshy tube. Were a like correlation between the shell and its inhabitant to hold good in other families of Mollusca, the classification of shells would then be a subject of much importance, and worthy the attention of the scientific naturalist: unfortunately, the reverse of this is frequently the case.

The part called the *operculum*, which is present in certain univalve molluscs, is a plate consisting of layers of sometimes calcified, sometimes uncalcified, albumen, attached to a disc at the back part of the foot, and forming, when this is retracted, a more or less perfect defence to the outlet of the shell.

Some opercula increase by the addition of matter to their entire circumference; and these are either concentric, as in *Bithynia* and *Paludina*, or excentric, as in *Ampullaria* and most of the Pectinibranchiate molluscs: other opercula grow by the addition of matter to part of their circumference; and these are either spiral or imbricated: in the latter, the layers of growth succeed each other in a linear series. No operculum presents an annular form. As the operculum sometimes varies in structure in

species of the same genus, as, e.g., of *Vermetus*, as, moreover, this part is inconstant even as to its presence in species of the same genus, as in the *Volutes*, *Cones*, *Mitres*, and *Olivæ*; and as some genera in a natural family, as *Harpa* and *Dolium*, among the Buccinoids, are without an operculum, while the other genera of the same family possess that appendage, it obviously affords characters of very secondary importance in a scientific classification of the Univalve Mollusca. Much confusion indeed might have been introduced into the science of Malacology, if the opinions of those conchologists who have proposed to classify shells from the modifications of the operculum had been much respected by naturalists.

True bivalve shells are peculiar to the Acephalous Mollusca; and their presence is constant, although they are in a few instances too small to cover the whole of the body, and in the ship-borers (*Teredo*) exist only as small instruments, limited to the function of excavating the burrows inhabited by these molluscs. But all the species in which the bivalve shell is in adequate to the protection of the whole of the body derive extrinsic defence by burrowing in sand, or stone, or wood: and they also commonly line their burrows with a layer of smooth and compact calcareous matter, forming a tube. This calcareous tube, in some cases, is of considerable size and thickness, as in the *Teredo gigantea* or *Septaria* of Lamarck. In the *Clavagella* one valve, and in the *Aspergillum* both valves, are soldered to this tube, which, in the latter, presents a peculiar modification of its exposed extremity, which resembles the end of the spout of a watering-pot. No two shells can present a greater contrast than do those of the *Placuna* and *Aspergillum*; yet the organisation of their respective constructors is essentially the same. In a classification of shells, the calcareous tubes of the *Dentalium*, *Serpula*, *Aspergillum*, *Vermetus*, &c. would be associated in the same general group; but we need only to observe how these products of animals, belonging not only to different classes, but to distinct primary divisions of the animal kingdom, are arranged in the cabinets of collectors, to be convinced that Conchology, as a classificatory science, apart from Malacology, no longer exists.

With regard to the structure and physiological relations of bivalve shells, it may be observed, first, that in all Acephalous Mollusca which breathe by distinctly developed lamellated gills (*Lamellibranchiata*), one valve corresponds to the left, the other to the right side of the animal; but in the Brachiopodous Bivalves, one valve is applied to the ventral, and the other to the dorsal aspect of the animal.

In all the Lamellibranchiate Bivalves which are free, the two valves are symmetrical, and the shell is termed *equivalve*: in all those which adhere by one of their valves to foreign bodies, this valve is deeper and larger than the unattached valve: such shells are termed *inequivalve*. Of those Acephalous which are attached

CONCHOLOGY

to foreign bodies by means of a byssus, some, as *Tridacna*, *Saxicava*, and *Byssio-arca*, are equi-valve, and both valves are notched, to form the hole for the passage of the byssus; while others, as the *Pectines*, *Avicula*, and *Peda*, are inequivalve, the byssus passing through a groove in the right valve.

Linnaeus, who first introduced precision into the description of shells, defined several points requisite to be noticed in the outer and inner surface of a bivalve shell; but the epithets, which his comparison of the bivalve selected for illustration induced him to attach to those parts, have been abandoned and changed. If the shell of the common cockle (*Cardium edule*) be examined, each valve will be seen to be produced into a conical prominence, bent towards, and nearly meeting at, that part by which the valves are joined together. These prominences are termed the *umbones*. The apex, or beak of the umbo, corresponds to the apex of the univalve shell, and is the point at which the development of the bivalve commences. When the apex is directed in the transverse plane of the shell, and so placed that a bisection of the shell in that plane through the apices shall divide the valve into two equal parts, the shell is termed *equilateral*: of this form the common scallop (*Pecten*) is an example. When, upon a similar division, a slight difference is observed in the two valves, the shell is termed *sub-equilateral*; but where the difference is well marked, it is an *inequilateral* bivalve. When the apex is bent, as is commonly the case, out of the transverse plane,

wards and the hinge above—in the position, in fact, in which the living animal would place itself if it were creeping forwards from the observer—the right valve will of course correspond with the right hand of the observer, and the left with the left. (Fig. 4 is the left valve of a *Cytherea*; *a* is the upper or dorsal margin, *b* the lower or ventral margin, *c* the anterior, *d* the posterior margin, *e* the apex of the umbo, *f* the lunule.) Now, if a Bivalve in which the apices have a spiral twist, as an *Isocardia* or *Diceras*, be placed in the above position, and compared with the univalve shell of a *Concholepas* or *Purpura*, it will be seen that the left valve corresponds with the ordinary or dextral spiral Univalve, and the right valve to the perverse or sinistral Univalve. Instances, however, have been met with where the characters of the valves of the Bivalve were reversed, like the occasional exceptions in the *perverse* sinistral Univalves before mentioned.

When the circumference or margin of one valve fits exactly at every part to that of its fellow, it is said to be *regular*, or entire; but if it be notched at any part, so as not to come into contact with the corresponding part of the opposite valve, it is *irregular*, or emarginate.

With respect to the outer surface of a Bivalve, the parts called *umbones* and *apices* have already been defined, and the upper or dorsal and anterior margins of the valve determined. If we continue our examination of the exterior surface of the Bivalve, we shall find, in most cases, anterior to the apices, a depression of variable extent and depth. This is the *lunule* (*f*, fig. 5): it may be cordiform, or crescentic, lanceolate, oval, oblong, deep, superficial, &c. Behind the apices is another depression, longer and narrower than the lunule, and which is called the *fissure* (*g*, fig. 5), and its margins *lips*. Behind the fissure there is sometimes a small depression, called the *suture* (*h*, fig. 5). The general more or less convex surface of each valve is called the *venter*, or belly, which terminates in the *limb*, circumference, or margin.

The most important part of the margin is that which is modified to form the joint or hinge upon which the two valves open and shut. This part is called the *cardinal edge*, and generally presents certain prominences and depressions, the projections of one valve interlocking with the depressions of the other. The projections or *teeth*, together with the cavities or *cardinal pits*, are very regular in their formation in each genus and species of Bivalve. What is of more importance is, that every modification in the structure of the hinge is generally found to coincide with some recognisable and more or less important difference in the organisation of the soft parts; so that conchologists have justly attached great value to the characters derivable from the hinge, especially for the purpose of generic distinctions. When the teeth are situate beneath the apex or centre of the hinge, they are called *cardinal*; when they are removed from the centre of the hinge, they are named *lateral teeth* (*i*, fig. 6); when

it is always directed more or less towards the anterior part of the shell. If such a Bivalve shell as a *Cytherea* or *Isocardia* be held before the observer, with the umbones directed for-

CONCHOLOGY

two only are present, one is called *anterior*, the other *posterior*; when there are three, they are distinguished respectively as the *anterior*, *median*, and *posterior* teeth; but when the hinge is composed of a great number of teeth, it is said to be *serial*, as in *Arca*. The direct medium of union of the two valves is a dense fasciculus of elastic albuminous fibres, generally of a brown colour, called the *ligament* or *elastic ligament*. The fibres of this part are attached by their extremities to the two valves, which, in most cases, present a particular depression for their reception. The ligament is always so long as to prevent the actual closing of the valves, except when its elasticity is overcome by a certain force, as by that of the contraction of the adductor muscle or muscles. Thus the inorganic power of elasticity is made the direct antagonist of a vital and muscular contraction; and as the patent condition of the bivalve shell is that which the exigencies of the animal most constantly require, it is assigned to a force which can act without ever causing fatigue, while the occasional or protective action of forcibly closing the valves is due to an action under the immediate control of the will or instinctive sensation. The modifications of the internal surface of a bivalve shell are, perhaps, the most interesting and important; as they relate immediately to the structure of the soft parts, and bespeak the general nature of the organisation of the animal. Hence they afford the characters by which the habits and structure of an extinct genus may be to a great extent determined.

The adductor muscles leave well-marked impressions on the inner surface. If there be but one muscular impression on a valve, then it belongs to a *monomyary* or *unimuscular* Bivalve; and if neither valve of a fossil shell presenting this character has been immediately attached to foreign bodies, then the laws of coexistence warrant the inference that the constructor of such a Bivalve possessed a byssus, and the muscular organ called the *foot*: but that the foot was developed only to the extent adapted to serve as an instrument for moulding the soft fibres, and regulating the attachment of the byssus.

If each valve of a bivalve shell exhibit two muscular impressions, it proves the species to be *dimyary* or *bimuscular* (*k* is the anterior, and *l* the posterior muscular impression in the *Cytherea*, fig. 6); if, moreover, there be a thin small muscular depression beneath the cardinal hinge, we have then an indication that the animal possessed a large foot, organised to serve as a locomotive or burrowing fleshy organ, the retractive muscle of which was inserted in the above depression. The line continued between the impressions of the two adductors indicates, by its depth and breadth, the development of the muscular margin of the mantle, and is called the *pallial impression* (*m*, fig. 6). If this line be continued uninterruptedly, parallel with the margin of the valve, we may be assured that the animal was

either without siphons, or had them of very small size; but if the pallial line be broken by an angular notch (*n*, fig. 6) continued inwards before its junction with the posterior muscular impression, then it may be certainly inferred that the animal had well-developed muscular tubes or siphons for respiration, with all the concomitant powers and habits. Thus the general organisation of the soft and perishable fabricator of a bivalve shell may be as certainly determined by the evidence of its fossilised enduring case, as that of a vertebrate species by the structure of its skeleton. The more immediate affinities of the Bivalve are revealed by the modifications of the hinge.

It sometimes happens, however, that the whole of the internal or nacreous stratum of a fossil bivalve shell is destroyed, especially if it have been embedded in porous chalk; and as the muscular impressions and the articular structure of the hinge are composed exclusively of the inner stratum of the shell, the means of determining the nature and affinities of the animal in that case are lost; and, unless the observer were acquainted with the texture and structure of the bivalve shell, he would run the risk of mistaking the part of a decomposed Bivalve for the whole of some nondescript *Acardian* species, as those Bivalves are termed in which the hinge is naturally wanting.

Each valve of a bivalve shell consists of two strata, distinct in texture and in their organs of formation. The internal stratum is deposited in nearly parallel layers, by the central and posterior parts of the mantle: it forms the smooth iridescent lining of the shell called *mother-of-pearl*. The outer stratum is secreted by the thick glandular margin of the mantle, and consists of conical fibres, resting obliquely by their apices, or narrower ends, upon the nacreous laminae. The thickness of the two strata of the shell always preserves an inverse ratio, the outer one being thinnest at the *umbo*, and thickest at the margin; the inner one the reverse.

One hundred parts of oyster-shell give—

Carbonate of lime . . .	98·3
Phosphate of lime . . .	1·2
Insoluble animal matter . .	0·5

100·0

Most univalve shells are composed of three strata, which consist of layers of rhombic or prismatic crystals, differently arranged in the adjoining strata. The chief difference of structure depends on the relative quantity of the animal to the earthy constituents of the shell.

Hunter discovered that the molluscan inhabitants of shells had the power of absorbing a part of the shell previously formed; a fact which has been confirmed by subsequent observers, and which gives rise, in several species, to singular modifications in the form and structure of the shell in the progress of growth. Another change of form is due to the physical decomposition or destruction of a part

CONCLAVE

of a shell: this occurs to the apex of certain Univalves, after they have been evacuated by their original occupant, in the widening and lengthening of the shell to accommodate it to an increase of bulk. Such shells are said to be *decollated*, as in *Cerithium decollatum*, *Helix decollata*, &c. An analogous partial decomposition always obtains in many *Uniones* and *Anodontes*, of which the *umbones* are then said to be *decorticated*, the external coloured layer or bark of the shell being worn away. There is no general law or uniformity in the mode in which the inhabitants of either univalve or bivalve shells dispose of that part of their calcareous abode which they evacuate in the progress of their growth. In the decollated shells, the vacated spire is partitioned off by the formation of a thin nacreous plate; and its walls being thin and fragile, it is then broken away, as above described. In *Vermetus gigas*, the vacated portions of the tube are successively partitioned off, and a series of concave plates or septa developed; but the part of the shell thus divided into chambers, or *cameræ*, is retained. The *Spondylus varius*, among Bivalves, offers an analogous structure. In the pearly nautilus, the vacated portion of the shell is converted into a series of chambers by the development of calcareous septa in greater number and regularity than in any Gastropodous Univalves; and the partitions are perforated by a membranous tube or siphon, the deserted chambers being converted, by the superaddition of this part, into a hydraulic machine, perfectly adapted to the habits and exigencies of the animal. The like structure, with various modifications, obtains in the extensive, but mostly extinct, race of 'Siphoniferous' Cephalopods. In the Argonaut, the vacated spire of the shell is not partitioned off, but is retained in full communication with the inhabited part, and made subservient to the reproductive economy of the species. In the *Mytilus antiquus*, the posterior part of the shell, as it is deserted, is progressively filled up with a dense, solid, subtransparent crystalline deposit of carbonate of lime. A deposit of similar calcareous material, in a less degree, fills up the deserted spire of the shell in some species of *Cassia*, *Mitra*, *Triton*, &c.; and in the long *turreted* shells of the *Terebræ*, *Cerithia* &c. the deposition of this dense material in the vacated apex is the preventative, instead of the cause, of decollation.

Conclave (Lat. *con*, together, and *clavis*, a key). The assembly of cardinals, especially so called when met for the election of a pope. It begins the day following the funeral of the deceased pontiff. The cardinals are locked up in separate apartments, and meet once a day in the chapel of the Vatican (or other pontifical palace), where their votes, given on a slip of paper, are examined. This continues until two-thirds of the votes are found to be in favour of a particular candidate. The ambassadors of France, Austria, and Spain have each the right to put in a veto against the election of

CONCORDANCE

one cardinal, who may be unacceptable to their respective courts.

Conclusion (Lat. *conclusio*). In Logic, that proposition which is inferred from certain former propositions, termed the *premises* of the argument.

Concomitance (Lat. *con*, and *comitor*, I accompany). The relation which exists between two sets of variables, such that when those of the one set are replaced by certain functions of themselves, those of the other set become likewise replaced by definite functions of themselves. The most important kinds of concomitance are cogredieny and contragredieny. [COGREDIENT and CONTRAGREDIENT.]

Concomitant. A term of modern Algebra, applied to a quantic which is related to a given system of quantics in the following manner: Let u_1, u_2 , &c. be a given system of quantics, which by linear transformation of their variables become converted into u'_1, u'_2, u'_3 , &c. and let u and u' be quantics respectively derived from these two systems according to the same definite rule; then if u is converted into mu' , where m denotes some power of the modulus of transformation, by the same or by reciprocal systems of linear transformations of its variables or facients u is said to be a *concomitant* of the given system u_1, u_2 , &c. If u should contain no variables, and be therefore identically equal to mu' , it is called an *invariant* of the given system of quantics; if, containing variables, it should be converted into mu' , by the same linear transformations it is called a *covariant*; but if its conversion into mu' should require linear transformations reciprocal to those first employed, it is called a *contravariant*. Lastly, if u should contain two sets of variables and still become converted into mu' by transforming one set by the original and the other by the reciprocal substitutions, it is called a *mixed concomitant* of the given system of quantics. Concomitants, therefore, embrace covariants and contravariants; in describing the latter terms, further details and illustrations will be given. It is scarcely necessary to add that the given system of quantics may consist of a single individual.

Concord (Lat. *concordia*). In Music, a combination of two or more sounds, forming harmony agreeable to the ear.

Concordance. A Biblical index, in which all the leading words used in Scripture are arranged alphabetically, and a reference made to the various places in which they occur. The importance of this class of works was early appreciated, and a vast deal of labour has been expended in compiling them. Concordances have been made of the Greek Septuagint, the Greek Testament, the Latin Vulgate, and the English Old and New Testaments; a full list of which will be found in Watt's *Bibliotheca Britannica*, and in Orme's *Biblia Biblica*. The first Concordance was compiled by Cardinal Hugues de St. Cher, who died in 1262. The best English Concordance is that of Cruden,

CONCORDAT

which appeared in 1737, and still maintains its ground as an authority.

Concordat. An agreement or convention upon ecclesiastical matters made between the Pope and some temporal sovereign, as that between Pius VII. and Bonaparte in 1802, by which the Roman Catholic religion was re-established in France; on which occasion the Pope recognised the new division of France into sixty sees, instead of the much greater number which had existed before the Revolution, the payment of the clergy from the national revenues, and the appointment of the bishops by the civil authority. Originally the term was applied to agreements regulating mutual rights between bishops, abbots, priors, &c. Many of the German powers possess concordats with the see of Rome; but the most celebrated is that of August 18, 1855, between Austria and the Pope, whereby the former surrendered more than all the ground which had been won from the latter by Joseph and Leopold; it appears, however, to be yet (1865) unsettled how far this concordat has become part of the law of the land.

Concrete. [BÉTON; CEMENT.]

Concrete Term. In Logic, is so called when the notion of an attribute is regarded in conjunction with the object that furnished the notion; as *foolish* or *fool*. When the attribute is regarded in itself, it is called an *abstract term*; as *folly*.

Concussion (Lat. *concussio*, from *concutio*, *I shake*). A term generally applied to injuries sustained by the brain, independent of fracture of the skull, as from blows and falls. More or less insensibility, sickness, impeded respiration, and irregular pulse are the first symptoms; but these subside, and the sufferer often becomes more easy and collected; yet, although the symptoms apparently abate, dangerous inflammation may be going on, and a fatal termination ensue. In all accidents of this kind, where, as is commonly said, persons are *stunned*, the most cautious treatment should be adopted, and no time lost in obtaining skilful professional aid.

Concussion. In Law, the unlawful forcing of another by threats, or by the abuse of office or rank, to yield up something of value. The term is now unknown to English, though common in foreign jurisprudence.

Concyclic Quadrics. Surfaces of the second order, which give circular sections when cut by the same two systems of parallel planes. Thus,

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} + \lambda (x^2 + y^2 + z^2) = 1,$$

for any values of λ represents a quadric surface concyclic and concentric with the ellipsoid (a, b, c). A system of concentric and concyclic quadrics may be regarded as a particular case of a system of quadrics having a common curve of intersection, and the reciprocal of such a system will be a system of confocal quadrics. The properties of one system, therefore, may be at

CONDITIONAL PROPOSITION

once deduced from those of the other. [CONFOCAL QUADRICS.]

Condensation (Lat. *condensatio*). The rendering a body more dense, compact, or of greater specific gravity, by bringing its particles into closer proximity. The term is commonly applied to the conversion of a vapour or gas into a liquid or solid either by the application of cold or pressure.

Condenser. The common name of various modifications of apparatus used in cooling heated vapours down to the temperature at which they become liquid. The *worm-tub* form is that most frequently employed in distillations. It is simply a long metal pipe coiled round the inside of a tub, one end being attached to the still, the other passing out near the bottom of the tub; cold water placed in the tub cools, and causes to condense, any vapour that may be passing through the worm. When in use the water in the tub is constantly renewed by pouring fresh quantities through a long funnel reaching to the bottom, the heated water being allowed to flow off by a spout near the top. *Liebig's condenser* consists of a glass tube passing through a wider and shorter metal tube, the two being fixed together at each end of the metal tube by a perforated cork. An entrance pipe and exit pipe are placed at opposite extremities of the metal tube, so that a current of cold water can be made to circulate in the space between it and the glass tube.

Condition (Lat. *conditio*). In Law, has been defined in the most general sense, 'A restraint annexed to a thing, so that by the non-performance the party shall receive loss, and by the performance advantage.' It is most commonly used to signify a term whereon a grant is made: e.g. grant of an estate to A, on condition that the grantee shall pay such a sum on such a day, or else his estate shall cease. Conditions of this description may be implied by law: as, where tenant for life enfeoffed one in fee simple, he formerly forfeited his estate for the breach, as it is said, of the implied condition not to grant a greater estate than his own. Conditions are *precedent*, when an estate is gained on the performance of them; *subsequent*, when the condition is to be performed after the acquisition of the estate which is lost by its non-performance. But the distinctions between these two classes are numerous and minute. In general, where a condition is of such a nature that compensation can be made for its non-performance, equity will relieve the party breaking it from the consequences of the breach on making such compensation.

Conditional Proposition. In Logic, is one which asserts the dependence of one categorical proposition on another: e.g. 'If the wind changes, it will rain.' The proposition from which the other results is termed the *antecedent*; the resulting proposition the *consequent*. A conditional syllogism is one in which the reasoning depends on a conditional proposition. It is of two sorts, *constructive*

CONDOTTIERI

and *destructive*; as, 1. If $A=B$, then $C=D$; but $A \neq B$, therefore $C \neq D$. 2. If $A=B$, then $C=D$; but C is not equal to D , therefore A is not equal to B . The connection between the antecedent and consequent of a conditional proposition is termed the *consequence*.

Condottieri (Ital. *leaders*). In Italian History, a class of mercenary adventurers in the fourteenth and fifteenth centuries, who commanded military bands, amounting to armies, on their own account, and sold their services for temporary engagements to sovereign princes and states. One of the earliest and most famous among those leaders was the Englishman Sir John Hawkwood, who commanded in various Italian wars about the time of our Edward III. The bands under command of the Condottieri were well armed and equipped. Their leaders had in many instances considerable military skill; but, as they took no interest in national contests, except to receive pecuniary advantages, the wars between them became a sort of bloodless contests, in which the only object of each party was to take as many prisoners as possible for the sake of the ransom. This singular system of warfare was only put an end to by the more serious military operations of the French, who invaded Italy under Charles VIII. Although many Condottieri acquired much honour as well as emolument, one only attained to high rank and independent power; this was Francesco Sforza, originally a peasant, who in 1451 made himself duke of Milan, and transmitted that sovereignty to his descendants. [MERCENARIES.]

Conduction of Impressions. In Physiology, is the propagation of that state or action of a nerve-fibre, which is produced by the application of a stimulus, through the whole length of the fibre; it takes place with immeasurable rapidity, in the same way as electricity is said to be conducted along a wire.

Conductor. In Electricity. [ELECTRICITY.]

Conduit (Fr. from Lat. *conductus*, past. of *conduco*, *I lead*). In Architecture, a passage of very narrow dimensions, usually subterranean, for the purpose of secret communication between apartments. The name is also applied to pipes or passages for the distribution of water.

Condurrite. An arsenite of copper, named after the Condurrow Mine near Helstone in Cornwall, where it was originally discovered.

Condyle (Gr. *κόρυμβος*, a *knuckle*). The rounded head of a bone.

Condylepoda, Condylepoda (Gr. *κόρυμβος*, and *πῶς*, a *foot*). A name applied by Latreille to that subdivision of Encephalous articulate animals which have jointed feet. The Acephalous Cirripeds are excluded from this group, which consequently includes the Myriapoda, Insecta, Arachnidans, and Crustaceans.

Cone or Conical Surface. In Geometry, the surface generated by a right line of unlimited length which moves in any manner so as always to pass through a fixed point. The right line is termed the *generator*, *side* or *edge* of the cone, and the fixed point its *vertex*.

CONFEDERATION

The cone is said to be of the n^{th} order if any arbitrary right line cuts it in n , real or imaginary, points; in other words, if n of its generators lie in any plane through its vertex. It is further said to be of the m^{th} class if through any point (or line through its vertex) m tangent planes can be drawn. The order and class of the cone, therefore, coincide respectively with the *order* and *class* of any plane or twisted curve (*directrix*) upon which the generator may be supposed to rest during its motion. The properties of a cone are best studied by considering any one of its plane sections, for the singularities of both will obviously correspond. Thus to every double or stationary point on the section will correspond a *double* or *stationary edge* of the cone; to every double or stationary tangent a *double* or *stationary tangent plane*, and so on. Plücker's equations connecting the singularities of curves, therefore, are at once applicable to cones. The determination of a cone of given order or class, whose vertex is known, by means of points or planes is also obviously similar to that of a curve of the same order or class by means of points or tangents. [CURVE.]

The term *cone* is sometimes employed in a limited sense to indicate the *solid* enclosed by one sheet of a conical surface of the second order, and the plane of one of its circular sections, the latter being then termed the *base* of the cone. Such a cone is further distinguished as *right* or *oblique*, as the line joining its vertex to the centre of the circle is perpendicular or not to the plane of the base. A right cone is obviously a *cone of revolution*.

CONUS (Gr. *κῆνος*). In Botany, a term denoting that form of inflorescence called a *strobilus*, which is a spike, the carpels of which are scale-like, spread open, and bear naked seeds. Sometimes the scales are thin, with little cohesion; but they often are woody, and cohere into a single tuberculated mass.

Cone of Rays. In Optics, includes all the rays which fall from a near luminous point, or from a single point of a near luminous object, upon a given surface; for example, the object-glass of a telescope: also the rays thrown by the object-glass to its focus.

Confederacy (Lat. *confederatio*, from *con*, together, and *fœdus*, a *league*). In Politics, an alliance of independent states for a common object.

Confederation, the Germanic (by the Germans termed the *Bund*). Was formed at the congress of Vienna: the instrument by which it is constituted bears date June 8, 1815. This union was framed to supply the want of the ancient imperial government, dissolved in 1806. The constituent members are thirty-four monarchical states and four free cities, which enter the confederation as equal and independent. The diet of plenipotentiaries, which forms the representative body of the league, is permanent, and sits at Frankfort-on-the-Maine. When this diet meets as a *general assembly* (plenum), six states, viz. Austria,

CONFERENCE

Prussia, Bavaria, Saxony, Hanover, Wurtemberg, have four votes each; five other states, three each; four, two; the rest, one; making seventy in all. But in the making of fundamental laws, admission of new members into the confederacy, and on religious questions, unanimity is required. In the *ordinary* assembly of the diet, the votes are so apportioned as to make only seventeen in all: this is the assembly in which propositions are discussed, which are decided without discussion in the *plenum*. This ordinary diet manages the general affairs of the confederation. Austria presides in both diets. The principal objects of the confederation are: the examination of disputes between its members; mutual protection; reciprocal assistance towards securing internal tranquillity; the establishment of constitutions of estates in all the states; the establishment of certain central courts of appeal; legal equality of Christian sects; an international community of civil rights in some points; and finally, the regulation of the condition of mediatised princes and states. [MEDIATISATION.]

Conference. In English Parliamentary usage, a meeting of certain delegated members of the two houses to discuss the provisions of a bill respecting which there is a disagreement between them; usually on the subject of amendments introduced by one and rejected by the other. The principal rules relating to conferences are: 1. That a conference must be demanded by that house which is in possession of the bill. 2. It is the privilege of the House of Lords to name the time and place at which the conference shall be holden. 3. The house which asks the conference must in its message clearly express the subject-matter respecting which it is to be holden. 4. It is usual for the house desiring the conference to appoint a committee to draw up reasons to be offered in support of the measure which the house has adopted. These reasons are communicated by its managers (i. e. delegates) to those of the other house; and it is irregular for any member to go beyond these reasons, or to speak anything except by way of introduction to their delivery. 5. If the reasons alleged on both sides fail in producing agreement between the houses, what is termed a *free conference* is demanded; usually after two conferences have been holden without effect. In a free conference the managers are not tied down to follow a particular line of instructions (although they may have received such instructions from their house), but may discuss the provisions of the measure in a more liberal manner.

CONFERENCE has also been the frequent denomination of meetings of divines for ecclesiastical purposes. The conferences of Hampton Court (1604) and the Savoy (1660), between clergy of the church of England and Puritans and Presbyterians, are well known in English history. The annual meetings of Wesleyan preachers are styled *conferences*.

CONFESSOR

Confession, Auricular (Lat. *auricula*, dim. of *auris*, an ear). Is accounted by the church of Rome part of the sacrament of penance. It must be made to a priest, who is under solemn obligation not to reveal it; and must include every mortal sin. As an authorised practice of the church, this usage does not appear to be older than about A.D. 1215. Confession is also prescribed by the Greek church. Among Protestants, the Lutherans have retained it in a modified form; but confession to God is alone required in the church of England as preparatory to absolution.

Confession of Faith. A formula setting forth the opinions held by a religious community. The most important documents of this nature published prior to the Reformation are the APOSTLES', the NICENE and the ATHANASIAN CREEDS. [See these arts.] Since that period the Romanists refer, 1. To the decrees and catechism of the council of Trent, as containing a complete exposition, accompanied by an elaborate defence, of their opinions; 2. To the Creed of Pius IV., published in 1564, which begins with a statement of the Nicene creed, and proceeds to declare briefly and explicitly the additional tenets of the Romish church; 3. The exposition of the Catholic faith by Bossuet, as having been sanctioned by the Pope, is considered of secondary authority.

The most authentic symbol of the Greek church is that which was drawn up in 1642 by Mogila, the metropolitan of Kiow. It was approved with great solemnity by the patriarchs and principal clergy of that communion.

The reformed churches have in almost all cases drawn up summaries of their peculiar tenets, and require their ministers to express their assent to them. The church of England requires subscription upon ordination to the Thirty-nine Articles, and the three articles of the 36th Canon which relate to the supremacy of the king, &c. The Book of Common Prayer and the Homilies are also authorised statements of the doctrine of this community.

The symbolic books of the Lutheran church are numerous the principal are the Confession of Augsburg, drawn up by Melancthon in 1530; the articles of Smalcald by Luther, (1538); the Great and Little Catechisms of Luther (1529); and the Form of Concord (1579). The original symbol of the Scotch church is called the General Confession of the true Christian Faith, which was adopted by the king and nation, together with the Solemn League and Covenant, in 1581. A second was drawn up in 1680 by some of the principal ministers, in consequence of an order in parliament for that purpose. The Confession of the Westminster Assembly (in 1643) was declared in 1690 by an Act of the Scots Parliament to be the national standard of faith in Scotland.

Confessor (Lat.; Gr. *ἁγιασμένος*). In Ecclesiastical History, the title given to those who have undergone persecution for Christianity short of death. They were peculiarly honoured in the primitive church, together with the

CONFIGURATION

memory of those who had actually suffered (martyrs). In the Romish church, the term is applied to priests authorised to hear confessions.

Configuration. In Astronomy, denotes the position which the planets occupy relatively to each other.

Confirmation (Lat. *confirmatio*). The laying on of hands by the bishop, for the conferring of the grace of the Holy Spirit; a rite by which a person arrived at years of discretion takes upon himself the performance of the baptismal vow made for him by his sponsors. In the early ages this ceremony seems to have been accompanied very generally with the unction of the forehead. It is retained in the Christian church generally, and is regarded as a sacrament by the church of Rome.

Confiscation (Lat. *confiscatio*, from *fiscus*, a treasury). In the Civil Law, the punishment of forfeiture of goods or land to the public purse.

Conflict of Laws. The opposition between the municipal laws of different countries, in the case of an individual who may have acquired rights or become subject to duties within the limits of more than one state. In the language of Mr. Burge (*Colonial and Foreign Law*, 1. 5.), 'the right or claim which is in contestation before a judicial tribunal may present a conflict between the laws of the country in which he was born, or had a domicile, or had taken up a temporary residence, or in which his property, the subject of the claim, was situated, or in which the act, instrument, or testament on which the claim is founded was executed, or in which the contestation takes place. In this conflict of laws it becomes an important branch of jurisprudence to ascertain which should be selected, and the principles on which the selection is to be made.' The following are among the principal works on this subject: Rodenburg *On the Conflict of Statutes*, an Essay appended to his treatise *De Jure Conjugum*; Hortius, *De Collisione Legum*; Boullenois, *De la Personnalité et de la Réalité des Lois*; the American judge Story's treatise on the *Conflict of Laws*; and the above-cited work of Mr. Burge, *Commentaries on Colonial and Foreign Laws generally, in their Conflict with each other and with the Law of England*, 4 vols. 8vo. London 1837.

Confluent (Lat. *confluens*, running together). The cohesion or blending together of two bones which were originally separate. The occipital bone of man, ossified from four distinct centres, is an example.

CONFLUENT. In Medicine, this term is applied to eruptive diseases in which the pimples or pustules are not detached, but are so numerous as to form confluent patches, or even to cover the whole surface of the body: hence the term *confluent small-pox*.

Confocal Quadrics. In treatises on Plane Curves, conics which have the same foci are often termed *confocal quadrics*. Such quadrics when they intersect always do so at right angles, and the two tangents from any point to a conic are equally inclined to the tangent,

CONFOCAL QUADRICS

at that point, to the confocal conic which passes through it. The properties of a system of confocal conics, which are very numerous, are given in most text-books, and are deducible from those of conics inscribed in the same quadrilateral, since the lines joining the common foci and the circular points at infinity are common tangents to all the conics of the system: [FOCUS.] Confocal quadric surfaces are surfaces of the second order, whose principal sections are confocal quadric curves, and a system of such confocal quadrics may be regarded as a system of quadric surfaces inscribed in the same developable, upon which the imaginary circle at infinity and the three focal conics in the principal diametral planes are double lines; the portions of these planes, therefore, which are bounded by the focal conics, must be regarded as special individuals of the system of confocal quadric surfaces. Through any point in space three quadrics can in general be drawn so as to be confocal with a given one, and these three always cut one another in their lines of curvature, since they are mutually at right angles to each other. [LINES OF CURVATURE.] The normals to these three confocals at their point of intersection are the common axes of the several tangent-cones to the confocal quadrics. These tangent-cones are themselves confocal, i.e. have the same focal lines [FOCAL LINES], and those which intersect do so at right angles, so that any two confocal quadrics which cut one another appear to do so orthogonally from whatever point of view they may be regarded. The quadrics confocal to a given ellipsoid, for example, consist of ellipsoids, of hyperboloids of one and hyperboloids of two sheets. Of these surfaces those of the same species do not intersect one another, but each surface is cut perpendicularly by every confocal of the system which is of a different species. We may add that the reciprocal of a system of confocal quadrics is a system of concyclic quadrics, whence properties of the one system are easily deducible from those of the other. [CONCYCLIC QUADRICS.] The like-directed semi-axes of the three confocals which pass through any point, or suitable functions of the same, are termed the *elliptic coordinates* of that point. [COORDINATES.]

The theory of confocal quadrics is of the greatest importance in pure and applied geometry, and on this account is usually treated to considerable length in all good text-books. In the celebrated problem of the attraction of an ellipsoid, for instance, the properties of confocal ellipsoids play an important part. [ATTRACTION, CALCULUS OF.] Ivory, in his treatment of this problem (*Encyclopædia Britannica*, art. 'Attraction'), was led to the consideration of what he termed *corresponding points* on two confocal ellipsoids; that is to say, points whose distances from any one of the three principal diametral planes, common to the two quadrics, are proportional to the axes of the quadrics which are perpendicular to the plane in question. He has shown that the distance between two points, one on each of two confocal

ellipsoids, is always equal to the distance between their respective corresponding points; an important property frequently referred to as *Ivory's Theorem*. The plane of the greatest and mean axes $2a$, $2b$ of an ellipsoid may be regarded as the limit of a confocal ellipsoid, whose squared semi-axes have become equal to $a^2 - c^2$, $b^2 - c^2$ and 0; so that to every point (xyz) on the ellipsoid will correspond a point (ξ, η) in the plane of a , b , determined by the relations

$$\frac{x^2}{a^2} = \frac{\xi^2}{a^2 - c^2}, \quad \frac{y^2}{b^2} = \frac{\eta^2}{b^2 - c^2};$$

whence it can be easily shown that the points (ξ, η) which correspond to the points of a line of curvature on the ellipsoid all lie in a conic whose foci are the points corresponding to the umbilics. As a particular case, it follows that to any three points A , B , C on the elliptic section (a, b) of the ellipsoid will correspond three points A_1 , B_1 , C_1 on the focal ellipse. With respect to three such pairs of points, Jacobi has shown that the distances of any point (xyz) on the ellipsoid from A_1 , B_1 and C_1 , are connected by the same relations as those which obtain between the distances from A , B and C of the point (ξ, η) in their plane which corresponds to (xyz) . This remarkable theorem, known as Jacobi's, is the analogue of the well-known one in plane conics, in virtue of which the distances of any point of an ellipse from its two foci are related to one another in precisely the same manner as are the distances from the same foci of any point in the line which joins them.

Conformable. In Geology. When after the deposit of mineral matter the mass of deposits has consolidated itself, and assumed the definite features that distinguish it from other rocks, it frequently undergoes a change of position before another deposit is thrown down upon it. If the new deposit is parallel to the old one, it is said to lie *conformably* upon it; if it is not parallel, it is described as *unconformable*. These terms are in common use among geologists in reference to all stratified formations. The same terms are used whether the want of conformability is caused by elevation or by denudation of the lower bed.

Congé (Fr.). In Architecture, the same sort of moulding as the echinus, or the quarter-round: also a term applied sometimes to the cavetto; the former being called a *swelling congé*, the latter a *hollow congé*.

Congé d'honneur (Fr. *leave to choose*). The king's writ or license to the dean and chapter to choose a bishop in the time of vacancy of the see; a mere formal proceeding.

Congeners. Species belonging to the same genus.

Congestion (Lat. *congestio*, from *congero*, *I heap together*). When there is an unnatural accumulation of blood in the capillary vessels of any part of the sanguiferous system, the organ in which it takes place, and the functions of which are disturbed, is said to suffer under *congestion*: it induces a morbid condition of the

vessels of the part affected, which when once established is difficult of removal. Congestion of the brain, liver, or lungs is a frequent effect of fevers, though generally consequent upon a previous morbid condition of the organs.

Conglomerate (Lat. *conglomeratus*, part. of *conglomerare*, *I heap together*). In Anatomy, glands which are made up of many small glands, the ducts of which unite into one, as the salivary glands.

CONGLOMERATE. In Geology. A rock made up of rounded fragments of various rocks cemented together and re-formed. Conglomerates are sometimes called *pudding-stones* [which see]. The cementing medium of a conglomerate may be carbonate of lime, silica, or oxide of iron. Sometimes the cement is strong enough to hold the stones and rocks together so firmly that they break more readily than the cement. Conglomerates are of no special geological age, but are met with in various formations.

Congregation (Lat. *congregatio*, from *con*, and *grex*, a *flock*). At Oxford and Cambridge, the assembly of masters and doctors is so called, in which the ordinary business of giving degrees &c. is transacted.

CONGREGATION. In Ecclesiastical language, properly an assembly of the people for the purpose of divine worship. Companies of religious persons, forming subdivisions of monastic orders, are styled in the church of Rome *congregations*. The name is also applied to the congregations of cardinals, which serve as committees for the transaction of business of the see of Rome.

Congregationalists. A sect of Protestant Dissenters, who arose in this country as early as the reign of Queen Elizabeth, when Robert Brown maintained that every society of Christians meeting in one place for religious worship under its own laws and ministers formed a legitimate and independent congregation. The Congregationalists have been called, from their founder, *Brownists*, and in later times *Independents* [which see]. Each congregation appoints its own ministers by vote, and can remove them at pleasure. Their chief tenets are: the doctrines of predestination, total depravity, particular redemption, effectual grace and final perseverance.

Congress (Lat. *congressus*, from *con*, and *grederi*, *I go together*). In Politics, a meeting of the sovereigns of states, or their representatives, for the purpose of arranging international matters. The first general European congress was after the conclusion of the Thirty Years' War in Germany, at Münster and Osnabrück, 1648, which was followed by the peace of Westphalia. Remarkable general congresses have been: 1. Of the Pyrenees, 1659; 2. Of Aix-la-Chapelle, 1668; 3. Nimègue, 1678; 4. Ryswick, 1697; 5. Utrecht, 1713; 6. Aix-la-Chapelle, 1748; 7. Teschen, 1779; 8. Paris, 1782; 9. Versailles, 1785; 10. the Hague, 1790; 11. Rastadt, 1797; 12. Erfurt, 1808; 13. Vienna, 1814, concluded at Paris, 1815; 14. Aix-la-Chapelle, 1818; 15.

Troppau, 1820; 16. Layback, 1821; 17. Verona, 1822. (Phillimore *On International Law*, ii. 45.)

CONGRESS. The title of the national legislature of the United States of America. It consists of a house of representatives, and of a senate. The former is composed of members chosen every second year. The qualification of electors is the same with that required in their respective states for electors to the lower house in the state legislature. The number of representatives is apportioned according to the population of each state, and is altered every ten years, when the census is taken by authority. In making this estimate, the slave population is reckoned only at three-fifths of its amount. There cannot be more than one representative for 30,000 free persons. The senate is composed of two members from each state: the senators are chosen for six years by the legislature of the state. The house of representatives chooses its own speaker: the vice-president of the United States is, *ex officio*, president of the senate. Bills for revenue purposes must originate in the house of representatives; but are liable to the proposal of amendments by the senate. The senate has the sole power of trying impeachments; but it can only convict by a majority of two-thirds of the members present, and its sentence extends only to removal from office and incapacitation for holding it. The regular meeting of congress is on the first Monday in December annually. Every bill which passes the two houses is sent to the president for approval or disapproval; in the latter case, he returns it, with his reasons, to the house in which it originated: if, on reconsideration, it is passed again by a majority of two-thirds in each house, it becomes law. The powers of congress are strictly limited, and separated from those of the various state legislatures by the constitution.

Congreve Rocket. [ROCKET.]
CONGRUENCE. If the difference between two numbers a and b (positive or negative) be divisible by a third p , called the *modulus*, the first two are said to be *congruous* for that modulus. The symbolical expression of this property, first proposed by Gauss, is $a \equiv b \pmod{p}$, and is termed a *congruence*. Thus $7 \equiv 2 \pmod{5}$; $12 \equiv -2 \pmod{7}$; and $16 \equiv 0 \pmod{8}$. The modulus being the same, two congruences may be added, subtracted, multiplied or raised to any power, just like ordinary equations; so that if $a \equiv b$, and $a_1 \equiv b_1 \pmod{p}$; $a + a_1 \equiv b + b_1$, $aa_1 \equiv bb_1$, $a^n \equiv b^n$, in short $F(a) \equiv F(b)$, if $F(x)$ be the symbol of a rational and integral function with integers for coefficients. Further, one congruence may be divided by another provided the members of the latter are prime to the modulus. Thus since $147 \equiv 12$ and $7 \equiv 2 \pmod{5}$, we conclude that $21 \equiv 6$. Either member of a congruence is termed a *residue* of the other for the modulus to which the congruence corresponds. [RESIDUE.] Any number a which substituted for x renders $F(x)$ a multiple of p , is said to be a *root* or *solution* of the congruence $F(x) \equiv 0 \pmod{p}$. It

is evident that any number congruous to a will also be a solution; in speaking of the distinct solutions or roots of such a congruence, however, *incongruous* solutions are to be understood. An identical congruence is one which subsists for all values of x ; in order that this may be the case, its coefficients must obviously be multiples of the modulus. As in the theory of equations, it can be shown that no congruence, of which the modulus is a prime, can have more roots than it has dimensions. It may have less and even none. By FERMAT'S THEOREM the congruence $x^{p-1} - 1 \equiv 0 \pmod{p}$ has precisely $p-1$ roots, and from this fact we can deduce the number of roots of other congruences. The arithmetical theory of residues of powers is identical with that of *binomial congruences* of the form $x^m - 1 \equiv 0$, and is of great importance in the theory of numbers. Serret's *Algèbre Supérieure* and Poinso's *Réflexions sur la Théorie des Nombres* may be consulted with advantage by the student of this branch of the theory of numbers.

Conic Sections. In Geometry, the sections of an ordinary right (or oblique) cone by a plane, are termed *conic sections* or simply *conics*. According to the position of the plane, these sections have received the specific names *ellipse*, *hyperbola*, and *parabola*; in a restricted sense the term *conics* applies to these curves only. The ellipse is obtained when the plane of section cuts only one sheet of the cone, and obviously includes, as particular cases, the *circle* and the *point*. The hyperbola results from the section of the cone by a plane which meets both its sheets, and clearly includes, as a variety, a couple of right lines. The only remaining position is the intermediate one where the plane is parallel to one of the sides of the cone, in which case the section is termed a *parabola*; a variety of the latter is clearly a pair of coincident right lines. From this it appears, conversely, that the centre and plane of projection being properly chosen, any given conic may be projected into another of any required species.

The sections of the cone were first studied by the geometers of the school of Plato. They admitted, however, only the right cone into their geometry; and they supposed the section to be formed by a plane perpendicular to its side. Consequently the three sections were formed from three different cones, the angles at the vertex being right, acute, or obtuse. The parabola was produced from a right-angled cone, the ellipse from an acute-angled cone, and the hyperbola from an obtuse cone. Apollonius of Perga, according to Eutocius, was the first who showed that the three sections may be obtained from the same cone, whether right or oblique, and whatever the angle of its apex; the species of the curve depending on the different inclinations of the plane of the section to the cone itself. It has, however, been established that Archimedes, who flourished about forty years prior to Apollonius, was acquainted with the fact that

the three sections may be derived from the same cone. Pappus, in his *Mathematical Collections*, ascribes to Apollonius the names by which the three sections are designated: the term *parabola*, however, occurs in the writings of Archimedes.

No part of mathematics has been more thoroughly studied than that which treats of the properties of conics, and no curves play a more important part in geometrical and physical enquiries. The treatises on the subject which have appeared since that of Apollonius, and up to the one recently published by Dr. Salmon, are of course too numerous to mention. The ancient method of defining conics has, in modern times, given place to others which do not transcend the limits of plane geometry. Wallis and De Witt appear to have been the first to adopt this method, which has since become universal. The properties of the curves chosen for the purposes of definition have varied from time to time according as geometrical and algebraical methods became more and more perfected. Boscovich defined a conic as the locus of a point whose distances from a fixed point and a fixed line have a constant ratio. The fixed point and line are, respectively, coincident with a *focus* and its corresponding *directrix*, and the conic is an ellipse, parabola, or hyperbola, according as the constant ratio in question is less than, equal to, or greater than unity. According to still more recent geometrical methods, towards whose development Steiner and Chasles have contributed so much, a conic is frequently defined as the locus of the intersections of corresponding rays of two homographic pencils, or as the envelope of the lines which join corresponding points of two homographic ranges; whence it follows at once, amongst other properties, that a conic is in general determined by five conditions, such as those of passing through five given points, touching five given lines, &c. An infinite number of conics can be found to satisfy four given conditions; the whole system, however, is characterised by stating how many of the conics which it embraces pass through any assumed point, and how many touch any assumed line. These two numbers have been termed by M. Chasles (*Comptes Rendus*, 1864) the *characteristics* of the system, since all properties of the latter may be determined by them. M. Chasles' method of characteristics constitutes one of the most important of modern contributions to geometry.

In algebraic geometry it is shown that every equation of the second degree has a conic for its locus, and conversely that the equation of every conic is of the second order. Conics according to the modern method of classification, therefore, are termed *curves of the second order*. [CONVEX.] The equation of a conic, rendered homogeneous, being formed by equating to zero any ternary quadric [QUANTICS], conics are also frequently termed *quadric curves* or simply *quadrics*. The quadric represented,

in rectangular Cartesian coordinates, $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 0$ by the equation

$$ax^2 + by^2 + cz^2 + 2dys + 2esx + 2fzy = 0$$

will be an ellipse, hyperbola or parabola according as $f^2 - ab$ is negative, positive or zero; it will be a circle if $f = 0$ and $a = b$, and will break up into a pair of right lines when the *discriminant*

$$\begin{vmatrix} a & f & e \\ f & b & d \\ e & d & c \end{vmatrix}$$

vanishes. [DISCRIMINANT.]

Conical Point. A point on a surface, every line through which there meets the surface in two or more coincident points. The number of such coincident intersections determines the *order* of the conical point. Conical points are more frequently called *multiple* points. Thus the origin is a *double* point on the surface represented by the equation

$$u_2 + u_3 + \&c \dots = 0,$$

where u_1 is a homogeneous function of the 3rd degree in x, y, z . All the generators of the cone $u_2 = 0$ meet the surface in *three* coincident points, and of these generators the six which lie in the cubic cone u_3 meet the surface in *four* coincident points. The innumerable tangent planes to the cone u_1 are, in an especial sense, tangent planes to the surface, and the double point is a cusp on the section which each determines. The corresponding singularity on the reciprocal surface is easily ascertained.

Conichalotte. A mineral of a green colour, consisting essentially of arsenate and phosphate of copper, with traces of vanadic acid. It occurs at Hinajosa de Cordova, in Andalusia in Spain.

Conidia (Gr. *κόνη*, dust). A term sometimes used in describing Lichens, to denote the bodies which constitute the powdery matter called *soredia*, lying upon the surface of the thalli. By others they are called the *propagula*. Also the little reproductive cells of certain fungi.

Coniferae (Lat.). In Botany, a natural order of arborescent or shrubby Gymnosperms, inhabiting most parts of the world, and usually both resinous and evergreen. Their real organisation was, for a long period, but little understood, until Brown discovered that the ovules of the entire order are naked. No other race of plants can be named of more importance to mankind than this—first, for their resinous secretions, as turpentine, pitch, Canada balsam, &c.; and secondly, for their timber, which is used under the names of fir, pine, deal, cedar, sandarach, and many others. All the kinds of fir, cedar, juniper, pine, savin, cypress, and arbor vitae, are species of genera to this order, which appears from evidence to have existed in great among the earliest vegetation that clothed the surface of our planet. Their name marks their habit of producing their fruit in cones.

CONINE

Conine or **Conia**. An alkaloid existing in hemlock (*Conium maculatum*). It is a colourless volatile oil of powerful odour and acrid taste, obtained by distillation of the plant with alkaline water. It is intensely poisonous.

Coniostres (Lat. *conus*, *a cone*, and *rostrum*, *a beak*). A tribe of Insectorial birds or perchers, including those which have a thick robust conical beak, as the crows and finches.

Conistonite. A hydrated oxalate of lime from Coniston in Cumberland.

Conite (Gr. *κόνη*, *powder*). A magnesian carbonate of lime, found associated with certain zeolites, in the form of a powder, at Down Hill, county Derry; also in Iceland, Hessa, and Saxony.

Conium (Gr. *κόνη*, *hemlock*). A genus of Umbellifera, containing the well-known poisonous weed called Hemlock. This plant, *C. maculatum*, is known by its mouse-like smell; but the technical distinctions reside in the fruits, which are roundish, with five wavy corky ridges on each half, with no oil-channels (*vittæ*), and the albumen deeply furrowed on the inner side. It grows in hedges and by roadsides, and has a tall erect branched spotted smooth stem, smooth parsley-like leaves, and compound umbels of fruits. It is used in medicine.

Conjoint Degrees. In Music, a term used of two or more notes which immediately follow each other in the order of the scale.

Conjoint Tetrachords. In Music, two tetrachords or fourths, in which the same note is the highest of one and the lowest of the other.

Conjugal Rights. [MARRIAGE, LAW OF.]

Conjugate (Lat. *conjungatus*, part. of *conjugo*, *I yoke together*). An adjective frequently used in pure and applied mathematics, with reference to two quantities, points, lines, axes, curves, &c., which present themselves simultaneously and have reciprocal properties.

Conjugate Constituents of a Matrix or Determinant. Are those which are symmetrically placed with respect to the principal diagonal. [MATRIX.]

Conjugate Diameters. In *quadric* curves two diameters are said to be *conjugate* when each bisects all chords parallel to the other; each is the polar of the infinitely distant point on the other, and consequently parallel to the polar of every point on the latter, and therefore to the tangents at its intersections with the curve.

In *quadric surfaces*, three diameters are said to be conjugate when the plane of any two bisects all chords parallel to the third. Such a plane is always parallel to the polar plane of any point on the third diameter, and, therefore, also to the tangent planes at its extremities. The numerous properties of conjugate diameters are given in every good treatise on pure and algebraical geometry.

Conjugate or Reciprocal Lines. [KINEMATICS and ROTATIONS.]

Conjugate Point. This expression, although an objectionable one, is still in general

CONJUGATE TANGENTS

use, and denotes a double point of a curve at which the two tangents are imaginary. Such a point being altogether isolated from the curve, is sometimes called an *isolated point*, and its existence is only detected by the fact that the number of points in which any line through it meets the curve is two less than the order of the curve would lead us to anticipate. In the *conchoid* of *Nicomedes*, for example, which is a quartic curve having the equation

$$h^2 x^2 = (a - x)^2 (x^2 + y^2),$$

the origin is clearly a double point on the curve; the tangents at which are given by the equation

$$a^2 y^2 + (a^2 - h^2) x^2 = 0.$$

If a were greater than h , therefore, these tangents would be imaginary, and the origin would have no consecutive points on the curve.

Conjugate Points, Lines, and Triangles. Two points are said to be *conjugate* with respect to any conic when the polar of one passes through the other. Similarly two lines are conjugate with respect to the same conic when the pole of either lies in the other. Lastly, two triangles or trilaterals are said to be conjugate when each side of the one is the polar of a vertex of the other. In the last case the angle opposite any side and the pole of the latter are *corresponding vertices* of the conjugate triangles, and similarly any side of one triangle and the polar of the opposite vertex are corresponding sides. The three lines joining the corresponding vertices of conjugate triangles always meet in the same point, and the intersections of the three pairs of corresponding sides always lie in a line. A triangle each of whose vertices is the pole of the opposite side is called a *self-conjugate* triangle. Thus the diagonal points of a complete quadrangle (intersections of pairs of opposite sides) form a self-conjugate triangle with respect to every conic which passes through those points. In the modern treatment of the properties of conic sections, the theory of conjugate points, lines, and triangles is of the first importance.

Conjugate Tangents. Any two tangents at a point of a surface are said to be *conjugate* when each thereof touches all the curves of contact of circumscribed developables having the other for a generator. They are always parallel to a pair of conjugate diameters of the indicatrix, and form, with the inflexional tangents, a harmonic pencil. From the relations which exist between the radii of curvature of a surface and the semi-diameters of the indicatrix [INDICATRIX], it follows at once that the algebraical sum of the radii of curvature of any two normal sections through a pair of conjugate tangents is constant. The above definition of conjugate tangents is that given by Dupin (*Développements de Géométrie*), who first investigated their properties. A simpler definition would be: Any two tangents at a point on a surface such that the tangent plane at a consecutive point on either contains the other. (Salmon's *Analytical Geometry*.)

CONJUGATES, HARMONIC

Conjugates, Harmonic. [HARMONICAL POINTS.]

Conjugation (Lat. *conjugatio*). In Grammar, is to verbs what *declension* is to substantives—the sum total of the inflexions which they admit, corresponding to the various circumstances of time or mood under which an action is conceived to take place.

Conjunction. In Astronomy. When Mercury and Venus are in a line between us and the sun, they are said to be in *inferior conjunction*. When any of the planets are so situate beyond the sun, they are said to be in *superior conjunction*. Planetary bodies appearing near each other or a star are also said to be in conjunction.

CONJUNCTION. In Grammar, that part of speech which expresses the relation of propositions or judgments to each other. [GRAMMAR.]

Conjunctive Mood (Lat. *modus conjunctivus*). That modification of the verb which expresses the dependence of the event intended on certain conditions. [GRAMMAR.]

Conjuring (from the Lat. *conjurare, to conspire*). Under this name are included all performances needing sleight of hand, many of which, as the term implies, need the combined action of two or more persons. The ingenious tricks of conjurers have a practical value; for, though the serious arguments which are to refute the pretensions of mesmerists must be sought elsewhere, the credulity of the uneducated may receive some check when they find that the phenomena exhibited by spirit-rappers and magnetisers can be produced by persons who admit that they employ only ordinary human agencies.

Connaraceæ (Connarus, one of the genera). In Botany, a natural order of shrubby or arborescent Exogens inhabiting the tropics, and only distinguished with certainty from *Leguminosæ* by the radicle being remote from the hilum. They approximate very closely to the Cæsalpineous section of *Leguminosæ*; but their want of stipules and regular flowers will usually be sufficient to distinguish them from the great mass of the Papilionaceous section.

Connate (Lat. *connatus, born together*). The anatomical condition under which the ossification of the common fibrous or cartilaginous bases of two bones proceeds from one point or centre, and so converts such bones into one bone; as e.g. the *radius* and *ulna*, or the *tibia* and *fibula* of the frog. These structures are each to the eye single bones; but the mind, transcending the senses, recognises such single bone as being essentially two. The centnums of the two middle segments of the skull in fishes are connate.

CONNATE. In Botany, a term applied to leaves, when an opposite pair are joined together by the base around the stem, so that the latter appears to grow through them.

Connellite. A rare Cornish mineral, supposed by Connell (after whom it is named) to be a compound of chloride and sulphate of copper, with a little water. It occurs in prisms of a dark blue colour.

CONOID

Connivent (Lat. *conniveo, I wink*). A term used figuratively by botanists in describing the direction of organs, to denote a gradual inward direction, as in many petals. It is the same as *converging*.

In Anatomy, the term is applied to those valvular folds of the lining membrane of canals which are so disposed as to retard, while at the same time they permit, and, as it were, connive at, the passage of the contents of such canals as the *valvula conniventes* in the human intestine.

Connoisseur (Fr. from *connaître, to know*). This term is applied to those who are versed in a knowledge of the Fine Arts. The qualifications of a sound connoisseur are rarely met with, and the majority of those who pretend to judge of art come under the description of a well-known Italian author, of being '*conoscitori senza cognizione*.'

Cono-conus. A skew surface of the fourth order generated by a line moving on two directors, one of which is rectilinear and perpendicular to all generators, and the other is a circle usually perpendicular to the plane which contains its centre and the other director. The rectilinear director, and the line at infinity perpendicular to the latter, are double lines on the surface. [CONOID.] Its equation is

$$c^2 x^2 = y^2 (a^2 - x^2),$$

where a is the radius of the circular director, and c the distance of its centre, on the axis of y , from the rectilinear director or axis of x . The surface was discovered by Wallis.

Conohelix (Gr. *κωνος, a cone*, and *ελix, a spiral*). A genus of shells, intermediate between the *Cones* and *Volutas*.

Conoid (Gr. *κωνοειδής*). A skew surface generated by the motion of a line which always remains parallel to a plane and has a rectilinear director. When, as is usually the case, the directing plane and line are perpendicular to each other, the latter is a *line of striction* on the surface. This line being taken as axis of x , the equation of the surface may always be

reduced to the form $s = f\left(\frac{y}{x}\right)$, whatever may

be the nature of its second director. Should the latter be also a right line, not in the same plane with the first director, the conoid will be an equilateral paraboloid. [HYPERBOLIC PARABOLOID.] The *Cono-conus* of Wallis, already described, is also a conoid, and another well-known example is the *Skew Helicoid*, the curvilinear director of which is a helix having the rectilinear director for its axis. The under surface of a spiral staircase presents a familiar illustration of this conoid. A conoid may be regarded as having three directors, one curvilinear and two rectilinear, one of the latter being at infinity. If the first of these directors be a curve of the m^{th} order, then the order of the conoidal surface will be $2m$, and each rectilinear director will be a multiple curve on the conoid of the m^{th} order of multiplicity. [RULED SURFACE.]

CONOIDAL

The directing plane being horizontal, the *lines of level* on the surface will of course be the generators; the *lines of greatest slope*, since they cut the former lines perpendicularly, will obviously be projected into circles on the directing plane.

Formerly it was a custom with English writers to give the name *conoid* to any solid generated by the rotation of a conic section around one of its axes. In this acceptation, however, the term is obsolete, and has been replaced by that of a *quadric of revolution*.

Conoidal. Of the shape of a conoid. A term applied to the head of an elongated shot of that form. The service projectiles for cannon and small arms have conoidal heads.

Conops (Gr. *κόνωψ*, a gnat). A Linnean us of Dipterous insects, characterised by having an elongated, slender, pointed proboscis. It is at present subdivided into the genera *Bucetes*, *Prostena* and *Stomoxys*, *Myopa*, *Zodion*, and *Conops* proper: the larvae of the latter subgenus are developed within the abdominal cavity of the humble bees, and other Hymenoptera.

Consanguinity (Lat. *consanguinitas*).

Law, is the relationship between persons descended from a common ancestor; and is either lineal, between persons of whom one is descended in a direct line from the other (son, father, grandfather, &c.), or collateral, between such as lineally descend from the same ancestor (brothers, cousins, &c.). In lineal consanguinity, the father is related in the first degree to the son, the grandfather in the second, and so forth. In collateral, the computation is by beginning at the common ancestor and reckoning downward to the more remote of the persons compared: thus brothers are kindred in the first degree; uncle and nephew, or first cousins, in the second degree; and so forth.

Consuetudo, Courts of, and of Requests. Were courts for the recovery of small debts. The jurisdiction of these courts arose out of various statutes, beginning with 1 Jas. I. c. 14, their original appointment having been by order in council under Henry VIII. But these courts have been recently abolished, and have been replaced by the county courts, whose jurisdiction extends to the recovery of debts under £50., and ten of which are situated within and around the metropolis.

Conscripfit (Lat. *Patres Conscripfit*, or *Fathers Conscripfit*). A title of the Roman senators.

Conscription (Lat. *conscripfit*, a written list). The compulsory enrolment, for military or maritime service, of individuals taken from the population at large. The conscription, in the Roman commonwealth, was made not by lot, but by arbitrary selection by the consuls from among the bulk of the citizens when a levy was required. In France the conscription was established during the Revolution, before which period the armies of that country had been recruited by voluntary enlistment. The word is first used in a law of 1798. According

CONSIDERATION

to the law as at present established, all citizens are liable to the conscription at the age of twenty. Each arrondissement has its contingent allotted to it out of the total number required for the service, and this number is filled up by lot from the youths liable to the conscription. There are, however, various claims for exemption recognised by the law. The legal duration of the service is seven years. The governments of the United States and of the Confederate States have been compelled to resort to this system during the present war, in order to obtain soldiers.

Consecration (Lat. *consecratio*). The act of setting apart a person or thing to the service or worship of God: thus a newly built church is consecrated with certain ceremonies, varying in different communities. The admission of a bishop to his office is called his *consecration*.

Consensual Movements. In Physiology, when one motion gives rise to the production of other motions contrary to or independent of the will, the latter are so called: as, e.g., the contraction of the iris when the eye is voluntarily directed inwards.

Consentes Dii. A term by which the Latins distinguished their twelve chief deities—Juno, Vesta, Minerva, Ceres, Diana, Venus, Mars, Mercury, Jupiter, Neptune, Vulcan, and Apollo. The names of these deities and their attributes are for the most part distinct from those which the Greeks assigned to their gods; but as the literature of Rome took its tone and colour from Greece, so its mythology was mixed up with that of the latter country, those deities whose functions most resembled each other being confounded, till the above names became regarded as nothing more than the Latin appellations of the Greek divinities.

Conservatory (from Lat. *conservo*, I preserve). In Horticulture, a glazed structure in which exotic trees and shrubs are planted out in a bed of soil. It is distinguished from an orangery by its having a glazed roof, whilst that of the latter is opaque; and from a greenhouse by the plants being in the free soil, and thus growing from the floor, whilst in the greenhouse the plants are grown in pots placed on shelves, or on a stage or series of shelves rising one above another. They are exclusively used for the plants which are in a growing state during the winter, and are therefore warmed according to the temperature which such plants may require. One of the largest conservatories in the world is that erected at Chatsworth in Derbyshire, by the late duke of Devonshire, for palms and other tropical plants; it covers more than an acre of ground, and is above sixty feet high.

Consideration (Lat. *consideratio*). In Law, is the material cause of a contract, without which it is not binding on the party. Consideration is said to be either *expressed* or *implied*. An express consideration is where the motive or inducement of the parties to the contract is distinctly declared by its terms; as where a man bargains to sell his land for 100l.

CONSISTORY

It is implied, where an act is done, or a legal demand forborne, at the request of another, without an express stipulation: in which case, the law presumes an adequate compensation for the act or forbearance to have been the inducement of the one party, and the offer of the other; as where a person comes to an inn and makes use of it, intention to pay for the accommodation is presumed. Consideration is also either *valuable*, that is, for money or an equivalent; or it is of *natural affection*, certain degrees of relationship affording in some cases sufficient consideration for a gift.

Consistory (Lat. *consistorium*, a *place of assembly*). An assembly of ecclesiastical persons; also certain spiritual courts holden by the bishops in each diocese. At Rome the consistory denotes the judicial court constituted by the college of cardinals. The representative body of the reformed church in France is styled *consistory*. There is now, or should be, according to law, a consistory for every 6,000 Protestant souls, consisting of the pastor or pastors, and from six to twelve elders. The consistory names the pastor. There were in 1863 eighty eight reformed consistories in France (not including the Lutheran churches).

Consolidated Fund. Down to 1816, the exchequers of Great Britain and Ireland were kept separate, certain portions of the public revenue arising in each kingdom being especially appropriated to the discharge of the interest on its own debts, and other peculiar purposes. But on January 6, 1816, the separate exchequers were consolidated into one, and an Act was at the same time passed consolidating certain portions of the joint revenue of Great Britain and Ireland into one fund, hence called the Consolidated Fund, and providing for its indiscriminate application to the payment of the public debts, civil lists, and other specified expenses of both kingdoms. Some portions of revenue are not included in this fund; but it embraces by far the largest part of the public income. Thus, from March 30, 1859, to March 31, 1860, of a total nett income of 72,912,064*l.*, the consolidated fund included no less than 71,089,668*l.*: the expenditure on account of the peculiar charges to be defrayed by the fund during the same year amounted to 31,478,966*l.*, leaving a surplus of 41,433,098*l.* applicable to other objects. (Fairman *On the Funds*, 7th ed. p. 196; *Parl. Paper*, No. 347, Sess. 1860, &c.)

Consonance. [CONCORD.]

Consonant. [VOWEL.]

Conspiracy (Lat. *conspiratio*, *agreement*). In Law, is in the strictest sense an agreement of two or more persons falsely to indict one, or procure him to be indicted, for felony; who, after acquittal, may have his writ of conspiracy. In a more general sense, many species of combinations to injure another are termed *conspiracies*; as to procure one to be arrested, to defraud under certain circumstances, &c. Conspiracy is an indictable offence; and two at least of the persons indicted must be found guilty

CONSTABLE

to produce a conviction, as otherwise the offence is not proved against anyone.

Constable (Fr. *constable*, from Lat. comes stabuli, *count of the stable*). A high officer in the monarchical establishments of the middle ages. In France, the first dignitary under the crown, commander-in-chief and supreme military judge. In that country the office was abolished in 1627, as conferring powers too dangerous in the hands of a subject. In England the last permanent lord high constable was Edward Stafford, duke of Buckingham, whose office was forfeited to the crown by his attainder in 1522; since which time it has only been occasionally conferred on particular emergencies. The title is supposed to have originated in the Lower Empire. (Ducange, *Gloss.*)

CONSTABLE. In Law. A constable is an officer particularly charged with the preservation of the peace, either within the hundred, where he is called *high constable*, or within the parish or tything, where he is called *petty constable*, and where he has generally superseded the tything-man. The duties of the high constable respecting the preservation of the peace are now merely nominal; but he is still of use to represent the hundred in certain legal actions, and to perform certain ministerial offices connected with the administration of justice, as, for instance, the return of jurors, which originally devolved upon the bailiff of the hundred. The functions of petty constable are still of great and daily importance. It is his business, in the first place, to interfere upon his own authority, and if necessary by apprehension of the offender, whenever a breach of the peace or other more serious offence is committed in his presence, or whenever he has sufficient information of a felony; and, in the next place, to execute all such warrants apparently and upon the face of them as shall be committed to his hands by competent authorities. He has a right, when impeded in the execution of his duty, to call upon bystanders for assistance, and has the power in case of sickness or disability to appoint a deputy to execute warrants in his stead. All constables were anciently appointed by the jury of the leet, but high constables are now appointed either at the courts leet of the franchise or hundred over which they preside, or, in default of that, by justices at special sessions. Petty constables are for the most part appointed by justices at special petty sessions (2 Steph. Bl. 677); and the person so appointed is compellable, under the penalties provided in stat. 5 & 6 Vict. c. 109, except in recognised cases of disability or exemption, to serve the office. A *special* constable is a person appointed to act as constable upon a particular occasion; and any two magistrates have, in case either of actual or apprehended riot, the power of calling upon all persons who would be liable to serve as petty constables to act as special constables, and their refusal is punishable. (Stat. 1 & 2 Wm. IV. c. 41, &c.)

CONSTELLATION

Constables are frequently appointed in pursuance of particular Acts of Parliament, as the police constables in London. And by 2 & 3 Vict. c. 65, c. 93, and other statutes, a county constabulary has been established generally both in England and Scotland.

Constellation (Lat. *constellatio*, from *con*, together, and *stella*, a star). In order to distinguish with greater facility the different stars, it has been the practice of observers, from time immemorial, to separate them into groups or clusters, which have received the name of *constellations*. These are represented by the figures of men or animals, or other objects to which they were fancied to have some resemblance. Hipparchus called them *Asterismi*; Aristotle and Hyginus, *Bodies*; Proclus, *Animals*; others, *Meteors*; but the term *constellation* has been long established by general usage. The origin of these figures and names is involved in impenetrable obscurity. By most authors the twelve constellations of the zodiac are supposed to have been established about 1,700 years before our era either by the Egyptians or the Chaldeans. Dupuis supposes them to have had an incomparably more ancient origin, and that their names are significative of the climate of Egypt at the epoch when the solstice was in Capricorn; that is, about 15,000 before Christ. But even on this hypothesis, namely, that the names of the zodiacal constellations, or *signs*, as they are frequently called, are significative of the seasons, it may be supposed that reference was made to the sign opposite to the sun, instead of that which the sun occupied; in which case the origin of the names would be referable to an epoch preceding our era by about 2,000 or 3,000 years. This arises from the motion of the equinoctial points, which regress or go backward annually among the stars, accomplishing half a revolution in about 12,500 years.

Hipparchus was the first who constructed a catalogue of the stars from exact observations. It has been preserved to our own times in the *Almagest* of Ptolemy, and contains 1,022 stars distributed among 48 constellations; namely, 12 in the zodiac, 21 to the north of the zodiac, and 15 to the south. Stars which were not comprehended in any of the constellations (and it is evident that there must be many such) were called by a Greek term signifying *unformed*; that is, not entering into the *forms* of the constellations. Several have been added in modern times, as the stars of the southern heavens became better known. A much clearer idea may be formed of the figures and relative positions of the constellations by inspecting a common celestial globe than from any description, however detailed.

The 48 constellations of Hipparchus are as follow:—

In the zodiac 12: *Aries*, *Taurus*, *Gemini*, *Cancer*, *Leo*, *Virgo*, *Libra*, *Scorpio*, *Sagittarius*, *Capricornus*, *Aquarius*, *Pisces*.

In the northern hemisphere 21: *Ursa Minor* (the Little Bear), *Ursa Major* (the Great Bear),

Draco (the Dragon), *Cepheus*, *Boötes*, *Corona Borealis*, *Hercules*, *Lyra*, *Cygnus* (the Swan), *Cassiopeia*, *Perseus*, *Auriga* (the Waggoner), *Ophiuchus* or *Serpentarius*, *Serpens*, *Sagitta* (the Arrow), *Aquila* (the Eagle), *Dolphinus* (the Dolphin), *Equuleus* (the Horse's Head), *Pegasus*, *Andromeda*, *Triangulum* (the Triangle).

In the southern hemisphere 16: *Cetus* (the Whale), *Orion*, *Eridanus*, *Lepus* (the Hare), *Canis Major* (the Great Dog), *Canis Minor* (the Little Dog), *Argo* (the Ship), *Hydra*, *Crater* (the Cup), *Corvus* (the Crow), *Centaurus*, *Lupus* (the Wolf), *Ara* (the Altar), *Corona Australis* (the Southern Crown), *Piscis Australis* (the Southern Fish).

To the above 48 constellations of Hipparchus, 12 near the south pole were added by Bayer, and represented in his *Uranometria*, the first edition of which appeared in 1603. These were: *Indus* (the Indian, or Indian Triangle), *Grus* (the Crane), *Phanis Apis*, or *Musca* (the Bee), *Triangulum* (the Southern Triangle), *Avis Indica* (the Bird of Paradise), *Pavo* (the Peacock), *Pica Indica* (the Toucan), *Hydrus* (the Hydra), *Dorado*, *Piscis Volans* (the Flying Fish), *Chameleon*. The two constellations, *Coma Berenices* (Berenice's Hair) and *Antinous*, were formed by Tycho Brahé; the first comprehending some of Ptolemy's unformed stars near Leo, and the second including others near *Aquila*. They are given in the catalogue of Riccioli, published in his *Astronomy Reformed* in 1666.

In the *Planispharium Stellatum* of Bartschius, published in 1624, the eight following constellations are found, and are said to have been formed by the moderns in that part of the heavens which is visible in Europe: *Camelopardalis* (the Giraffe), *Tigris*, *Jordanus*, *Vespa* (the Wasp), *Columba Noachi* (Noah's Dove), *Monoceros* (the Unicorn), *Rhombus* (the Rhombus or Rhomboid), *Gallus* (the Cock). The same constellations are met with in the Celestial Charts of Royer, published in 1679, with the exception of *Gallus*. *Vespa* is also changed into *Lis* (the Flower-de-luce), and *Crus* (the Cross) is added.

In the Charts of Hevelius, entitled *Firmamentum Sobiescianum*, and published in 1690, we find 10 new constellations: *Canes Venatici* (the Greyhounds, Asterion, and Chars), *Lacerta* (the Lizard), *Leo Minor* (the Little Lion, in place of *Jordanus*, mentioned above), *Lynx* (instead of *Tigris*), *Sextans* (the Sextant of Urania), *Scutum Sobiescianum* (Sobieski's Shield), *Triangulum* (the Little Triangle), *Fulpecula et Anser* (the Fox and Goose), *Cerberus* and *Mons Mænalus*.

To the above, *Cor Caroli* (the Heart of Charles II.) was added by Flamsteed, and *Robur Carolinum* (the Oak of Charles) by Halley.

Notwithstanding the additions already made to the constellations in the southern hemisphere since the time of Ptolemy, Lacaille found so many clusters of unformed stars, while observing at the Cape of Good Hope, that he added

CONSTITUENT ASSEMBLY

to the list no fewer than fourteen new constellations, to which he gave the following names: *Officina Sculptoria* (the Sculptor's Workshop), *Fornax Chymica* (the Chemical Furnace), *Horologium* (the Clock), *Reticulus Rhomboidalis* (the Rhomboidal Net), *Caelum Sculptorum* (the Graver), *Equuleus Pictoris* (the Painter's Easel), *Pyzis Nautica* (the Mariner's Compass), *Octans Hadleianus* (Hadley's Octant), *Machina Pneumatica* (the Air Pump), *Circinus* (the Compass), *Quadra* (the Square), the *Telescope*, the *Microscope*, and *Table Mountain*. Some still more recent additions have been proposed, particularly by Bode; among which are the *Honours of Frederick*, the *Sceptre of Brandenburg*, *Herschel's Telescope*, &c.; but they do not seem to be generally used in astronomical catalogues.

If the question were to be asked, What good purpose can be served by this multiplication of arbitrary divisions and fantastic names? we apprehend that no very satisfactory answer could be given. Astronomers doubtless find it convenient to classify the stars under certain divisions; but when the number of divisions becomes so great as to be remembered with difficulty, the advantage disappears. The arbitrary nature of the divisions also leads to great inconvenience, inasmuch as they are liable to much uncertainty, and to frequent change of boundary. Not only have the names in several instances been changed, but it seems to have been a common practice with astronomers and chart-makers to take stars from one constellation and give them to another, without any other rule than that of pleasing their own fancies. On this account it is frequently extremely difficult to identify stars (particularly in the southern hemisphere) in the different catalogues. It is to be wished that the whole of the constellations (excepting perhaps the forty-eight of Hipparchus and Ptolemy) were obliterated from our celestial charts and globes, and that observers in describing the places of the stars would confine themselves to a simple statement of their right ascensions and declinations, at least until some better arrangement and nomenclature shall have been devised and agreed upon.

Constituent Assembly. In French History, the first of the national assemblies of the Revolution; elected in 1788 as the States-General, dissolved in 1791 after proclaiming the constitution of that year.

Constituents of a Matrix or Determinant. [MATRIX and DETERMINANT.]

Constituents of the Roots of an Equation. Algebraists give this name to certain linear functions of the roots which occur in the theory of equations. The equation being of the n^{th} degree, any one, p_m , of the $n - 1$ constituents of its roots is defined by the formula,

$$p_m = x_1 + \omega^m x_2 + \omega^{2m} x_3 \dots + \omega^{(n-1)m} x_n,$$

where $x_1, x_2 \dots x_n$ are the n roots of the equation, and ω an imaginary n^{th} root of unity. The following relation between any root x_{r+1} and

CONSTITUTIONS OF CLARENDON

its constituents is easily deducible from the above definition:—

$$n x_{r+1} = \omega^{r(n-1)} p_1 + \omega^{r(n-2)} p_2 \dots + \omega^r p_{n-1} + x_r,$$

x_r being the sum of the roots or the coefficient, taken negatively, of the second term of the equation.

Constitution (Lat. *constitutio*). The collective body of the fundamental laws of a state; either contained in written documents, or established by prescriptive usage. Constitutions have been divided into three kind by political writers: 1. Those granted (octroyées) by monarchs to their subjects; 2. Those springing out of rights enjoyed independently by the people, or classes of the people, which in monarchical countries are recognised by the sovereign in his contract with the people; 3. Those founded on compact between sovereign powers, i. e. federal constitutions. In a certain sense, all states in which the power of a sovereign over his people, or classes of his people, is limited by law or legal usage in any particular, may be said to possess *pro tanto* a constitution; but, in ordinary language, only a government in which the power of legislation, or that of granting and withholding supplies to the sovereign, is vested in the people, or in a body of representatives elected by them or by a class of them, is termed *constitutional*. Constitutions have again been divided into—1. Those in which legislative power is exercised directly by the people (as in some small modern commonwealths, and in all the free states of antiquity); and, 2. Representative constitutions. The last again, as prevailing in modern Europe and America, has been divided historically into—1. Those which have originated from compact between several independent interests, as the sovereign, clergy, nobles, and commons, in feudal kingdoms; 2. Those formed artificially, in modern times, on the model of the British constitution; which, although arising out of the same causes which produced the feudal constitutions, assumed in the course of time a different and more comprehensive character.

Constitutions. In Roman Law, decrees of regular authorities, as prætors, &c.; more particularly decrees of the emperors, whether by decree, edict, or letter.

CONSTITUTIONS, APOSTOLICAL. An ancient code of regulations respecting the doctrine and discipline of the church, said by some to have been promulgated by the Apostles, and collected by Clemons Romanus. They appear to have been at one time admitted into the canon of Scripture. Their authenticity has been a subject of much dispute. They have been printed together with the so-called Canons of the Apostles. (*Cotelerii Patres Apostolici*, vol. i.; Krabbe's *Dissertations on the Apostolical Constitutions and Canons*, Hamb. and Götting. 829; Gieseler, *Ecol. Hist.* 1st period, 3rd div. 66.)

Constitutions of Clarendon. In English History, certain propositions, defining the limits of ecclesiastical and civil jurisdiction, drawn up at the council of Clarendon, near Salisbury,

CONSTRUCTOR

held by Henry II. A.D. 1164. (Hallam's *Middle Ages*, ch. vii. part ii.)

Constrictor (Lat. *constringo, I squeeze*). A name applied to the larger serpents, which overcome and destroy a struggling prey by throwing themselves round it in overlapping folds, and crushing it by their muscular force. The *Boa Constrictor*, properly so called, is a native of South America.

Construction (Lat. *constructio*). That branch of the science of Architecture which relates to the practical execution of the works required to carry out the artist's designs. It is immediately connected with the distribution of the different forces, and the strains of the parts and materials of a building, the properties and qualities of the various materials used, and the effects which they are likely to produce in their several places.

Consubstantiation. The term by which Luther expressed the opinion which he held upon the nature of the elements in the Eucharist, as distinguished from *Transubstantiation*, the doctrine of the Romanists. The latter asserts, as the word they use implies, that the bread and wine are changed into the body and blood, and lose their former substance, although they retain its appearance miraculously to the senses. The Lutherans deny this change; but affirm that while the bread and wine do still remain in their natural substance, the body and blood are at the same time transfused into them, and thus that both are actually partaken of together.

Consul (Lat.). In Politics, a public officer whose functions partake of the diplomatic and commercial characters. Such officers appear to have been first employed by the Italian republics to protect their merchants engaged in trade in the cities of the Levant. The consuls of European states in that region, and in Africa, are at the present time officers of more importance than those established in the cities of Christendom; as they exercise, according to treaties, civil jurisdiction over the citizens of their respective states. [CONSULAR JURISDICTION.] In general, the consul is not regarded as a minister or diplomatic functionary, and is subject to the civil authorities of the place where he resides. A resident English merchant, acting here as consul of a foreign country, is not exempt from arrest on meane process. English consuls are now salaried officers, under the Consular Act, 6 Geo. IV. c. 87, and the fees which they are still allowed to take are specified. Much question has been raised as to whether they ought or ought not to be allowed to trade, nor is this susceptible of any general answer under English usage.

Consuls. The supreme magistrates of Rome after the expulsion of the kings. Their number was two, and the period of their office one year; but there was no restriction as to the number of times the same individual might be elected. The power of the consuls was nearly the same as that of the kings; i. e. they were the supreme executive officers, but had

CONSULAR JURISDICTION

no legislative authority. The consuls were originally chosen only from the patricians, but afterwards from the plebeians also. The age required by law was forty-three years; but besides this it was requisite to have passed through the inferior offices of quaestor, aedile, and praetor. They were elected at the Comitia Centuriata, some months before their entrance into office, which took place at different periods of the year at different times, but finally in January. During the interval they were termed *consules designati*, or appointed consuls. Soon after their entrance into office, they cast lots for the provinces to fall to the share of each, the superintendence of which was conferred on them by the senate. Under the emperors the nominal office of the consulate was preserved, but its substantial power destroyed; the elections also became merely forms, the emperor appointing whom he pleased. Then too the custom was introduced of having several sets of consuls in one year; those admitted on the first day, however, gave their name to the year, and were distinguished from the others, who were termed *suffecti* (i. e. substituted), by the title *ordinarii* (i. e. regular). Persons also were sometimes dignified merely with the title without enjoying the office, and were then styled *honorary consuls*. Under Justinian the year ceased to be denominated by the name of the consul.

CONSULS. In French History, were the persons to whom, after the dissolution of the Directory in November 1799, was intrusted the provisional government of the country, and at whose suggestion it was agreed that France should be permanently subjected to consular authority. According to the constitution framed on this suggestion, Bonaparte, Cambaceres, and Lebrun, called first, second, and third consuls, were elected by the conservative senate each for ten years, and invested with different degrees of authority. But the senate having passed various decrees which curtailed the powers of the second and third consuls and augmented those of the first, the government was gradually assimilated to a monarchy, and after the lapse of four years and a half an easy transition was made from the consular to the imperial form; the title of emperor was substituted for that of consul; and the exercise of the sovereign authority, which indeed had been only nominally shared with his colleagues, was delegated exclusively to Napoleon Bonaparte.

Consular Jurisdiction. Under various treaties with foreign countries, British consuls have special jurisdiction, both civil and criminal, over British subjects established in those countries. The most remarkable instances are those of Turkey and China. In the former empire the British consular jurisdiction is of great antiquity, and is now regulated by orders in council, consolidated by that of August 27, 1860, which creates an officer with considerable power (Judicial Assessor at Constantinople) charged with the supervision of its exercise. In China it was established in 1815, after the first

CONSULARS

Chinese war, and is administered by a consul-general, subject (in certain cases) to the interposition of the supreme court at Hong Kong.

Consulars. The title given to Roman citizens who had been dignified with the office of consul.

Consultation (Lat. *consultatio*). In ordinary Legal language, is a meeting of the counsel engaged by a party to a suit, for the purpose of deliberating on the best mode of proceeding in the case.

Consultation, writ of. In Law, a writ granted by the king's court, whereby a cause which had been removed into such court by prohibition out of the ecclesiastical court is returned thither again. It is so called because it issues in consequence of the judges, on consultation, having found that the suggestion on which the prohibition was granted is false or not proved. [PROHIBITION.]

Consumption (Lat. *consumptio*, from *consumo*, *I waste away*). This term is commonly applied to a diseased state of the lungs, attended by emaciation, debility, cough, hectic fever, and purulent expectoration. It may be produced by a variety of causes; but hereditary disposition and scrofulous habit are leading causes which predispose to its most alarming form, namely, that which arises from tubercles in the lungs. Its first symptoms are cough; at first dry, but afterwards attended by mucous expectoration, difficult breathing, lassitude, and impaired appetite. These are succeeded by more copious expectoration of viscid or purulent matter, sometimes streaked with more or less blood; greater difficulty of breathing, pain in the side, especially on coughing or taking a full inspiration; and inability to lie with equal comfort upon both sides. The emaciation becomes more perceptible; and the pulse, at first not much affected, becomes full, hard, and quick. Frequent flushings and fever of a remittent character ensue, attended by chills and red sediment in the urine, but the tongue is not much altered, and the mouth is usually moist; the bowels, at first irregular, become habitually relaxed; profuse perspirations, attended by extreme debility and rapid emaciation, follow; the legs swell; and the patient sinks, generally retaining the senses, and even in hope and spirits to the last. In the early treatment of this disease the tendency to inflammatory action must be most cautiously encountered by bleeding, cupping, or blisters; the bowels gently opened by saline aperients; and the cough and irritability quieted by opium, henbane, or hemlock, and by small doses of expectorants. Tonics and acids require to be given with the utmost prudence; and after all, little except palliation can be effected. The diet must from the beginning be scrupulously attended to, and should be mild and nutritive, but not stimulant; and sometimes a temporary benefit results from change of air; but where the disease is once established, its effect is uncertain, and it is in many cases worse than injudicious to advise change

CONTACT

of climate. The inhalation of vapours of chlorine and iodine, in very minute quantity, has appeared to give in some cases a little temporary relief; in others it has proved decidedly mischievous; in none, permanently useful; and we must with regret assume that there has been some mistake in the supposed cures of established and constitutional consumption. In its very early periods, change of country, diet, habit, and occupation will sometimes seem to suspend its progress; it has also been checked by other diseases, and not unfrequently it lies dormant in females who breed quickly; but at a later period it again shows itself, and proceeds to its fatal end.

Consumption. In Political Economy. In the ordinary definition of the science, this term is recognised as one of the three objects of enquiry especially connected with the theory of wealth. Consumption is said to be productive, when it is the result of the employment of capital; and to be unproductive, when neither directly or indirectly it is made to contribute to production. Much of the importance, however, of this distinction, is historical. It gave a colour to many of Adam Smith's reasonings, and perhaps was the prominent cause of his *Enquiry*; but it takes a far less significant position in the modern method of the science.

Contact (Lat. *contactus*, a touching). In Geometry, the term *contact*, as applied to two curves, implies that the latter do not simply intersect, but have two or more consecutive points in common. The number of such consecutive common points determines the order of the contact. Thus two curves which have two consecutive points in common, are said to have a *two-pointic* contact, or one of the *first* order; if they have three consecutive common points the contact is *three-pointic*, or of the *second* order; if four, *four-pointic*, or of the *third* order; and so on. In short, the number of consecutive common elements is equal to the order of the contact. Thus two curves which simply touch each other, or have a common tangent, have a contact of the first order both with each other and with that tangent. If they have the same curvature, they have contact of the second order with each other and with the common circle of curvature. When the number of common points is sufficient to determine one of the curves completely, the order of contact is a maximum, and the latter curve is said to *osculate* the former. [OSCULATION.] Thus a circle is determined by three points, so that we can only demand from it a contact of the second order with any given curve. It is then called the *osculating circle*, or *circle of curvature*. [CURVATURE.] A conic being determined by five points may have contact of the fourth order with any curve of higher order than itself. The determination of such an osculating conic, called also the *osic of five-pointic contact*, has frequently occupied the attention of geometricians. Memoirs on the subject by Cayley, Spottiswoode, and others, will be found in the *Philosophical*

CONTACT, ANGLE OF

Transaxions and most modern mathematical journals. The methods of determining the curve which has contact of a given order with a given curve, are explained in all good treatises on the differential calculus.

The contact and osculation of surfaces is determined by that of their plane sections. On this subject Dupin's *Développemens de Géométrie* may be consulted with advantage. Amongst other things, the author there shows that the curvature at any point of a surface is precisely the same as that of any one of the innumerable quadrics which can be drawn to touch the surface at that point, so that its principal normal sections shall have contact of the second order with those of the surface itself. In fact, Euler's and Meunier's formulæ [CURVATURES OF SURFACES] at once show that under these circumstances all sections of the surface and of the quadric, by a plane through their point of contact, will have contact of the second order. The section of this osculating quadric by any plane parallel to the tangent plane of the surface gives at once the *indicatrix*; thence the radii of curvature, conjugate and inflexional tangents, and directions of lines of curvature, &c., are at once determined.

Contact, Angle of. In Geometry, the angle made by a curve line with its tangent. It is also called *angle of contingence* [ANGLE OF CONTACT], and is equal to the *angle of curvature*. Formerly the angle of contact was the subject of much metaphysical controversy amongst geometers. See an excellent account of the writings of Wallis, Peletarius, Clavius, Vieta, and others, on this subject, in the notes to Camerer's *Euclid*, Berlin 1824.

Contact, Stationary. [STATIONARY CONTACT.]

Contagion (Lat. *contagio*). The propagation of specific diseases from person to person. *Contagious poisons* communicate the property of producing similar poisons; the *small-pox* is a characteristically contagious disease. By some writers the term has been limited to diseases requiring *actual contact* for their communication; but contagious matter appears often transmissible by the air: hence the terms *immediate* and *mediate contagion*. Where diseases are propagated through the medium of the air, they are generally called *infectious*.

Contempt (Lat. *contemptus*). In Law, disobedience to the rules, orders, or process of a court of competent authority. Contempt in court is punishable by fine or imprisonment: for contempt out of court an attachment may be granted. Contempt of the king's prerogative, by refusing to assist him in the exercise of his lawful authority, &c., is a high misprison or misdemeanour. A breach of privilege of either of the houses of parliament is punishable by that house by censure or commitment, in the same manner as courts of justice punish for contempt. See May's *Parliamentary Practice*, chap. iii, for a full exposition of the law on this subject.

CONTINUAL PROPORTIONALS

Context (Lat. *contextus*). The general series of a discourse; when we cite a particular passage, we mean by its *context* the parts immediately preceding and following it, which determine or affect its sense.

Continents (from Lat. *contineo*, *I hold together*). The large unbroken tracts of land on the earth, whether altogether or entirely disconnected, are included under this name. Thus Europe and Asia together, Africa, North America, South America, and Australia, may all be thus regarded. There is absolutely no natural separation between Europe and Asia; and thus, although in descriptive and political geography they are distinct, in physical geography they are one.

EUROPE AND ASIA occupy a remarkable position in the northern hemisphere. Their shores are deeply indented with inland seas, gulfs, and bays [COAST LINES], and they are flanked by some large and important groups of islands. They include all the most ancient seats and centres of civilisation, with the exception of Egypt, and contain the principal and loftiest mountain chain of the earth, besides many that are subsidiary. Its rivers are not less remarkable; its plains and plateaus are of great extent, and its groups of animals and vegetables eminently important and valuable to the human race. The two AMERICAS, connected by the mighty chain of the Andes, are also strikingly interesting and extremely distinct in all essential peculiarities. AUSTRALIA is equally distinct. AFRICA properly belongs to Europe and Asia, and repeats some of their phenomena, with many that are altogether exceptional owing to its physical condition. Of all parts of the world, the western coast of Europe seems the best adapted to human requirements.

Continental System. In Modern History, the celebrated plan of the Emperor Napoleon for excluding the merchandise of England from all parts of the Continent. It was commenced by the decree of Berlin, issued November 21, 1806, which declared the British islands in a state of blockade, and made prisoners of war all Englishmen found in the territories occupied by France and her allies. The blockade thus instituted was far from complete; and in the course of events licenses were expressly granted by the government for its evasion, and became a source of revenue. It is more than probable that the decree was inoperative from the first. It is certain that Napoleon's soldiers were clothed in British fabrics; and, in effect, the chief value of the expedient has been to show that no precautions can prevent the importation of commodities from one country to another, though they may make it difficult or circuitous.

Contingence, Angle of. [ANGLE OF CONTACT.]

Continual Proportionals. Quantities are said to be continual proportionals, or in continued proportion, when the first is to the second as the second to the third, as the third to the fourth, and so on.

CONTINUED BASS

Continued Bass. In Music, the same as *thorough bass*. It receives the name from its continuation through the whole of a composition.

Continued Fraction. An ordinary continued fraction is a complex fraction of the form

$$F = a + \frac{1}{b + \frac{1}{c + \frac{1}{d + \frac{1}{e + \&c. \dots}}}}$$

a more convenient notation for which is

$$a + \frac{1}{b} + \frac{1}{c} + \frac{1}{d} + \frac{1}{e} + \&c.$$

It is said to be a *terminating* continued fraction when the number of *quotients* $a, b, c, d, \&c.$, is finite. It is obvious that any quantity whatever may be expressed in the form of a continued fraction. An ordinary fraction is always expressible in the form of a *terminating* continued fraction, and conversely any part of a continued fraction, breaking off at any quotient, may be converted into an ordinary fraction. Such ordinary fractions are called the *convergents* of the continued fraction, since their values converge towards the value of the continued fraction more and more the greater the number of quotients they embrace. If

$$\frac{A}{A_1}, \frac{B}{B_1}, \frac{C}{C_1}, \dots, \frac{P}{P_1}, \frac{Q}{Q_1}, \frac{R}{R_1}, \&c.$$

be the successive convergents formed by breaking off at the quotients

$$a, b, c, \dots, p, q, r, \&c.$$

respectively, we shall have

$$A = a, A_1 = 1; B = a + b + 1, B_1 = b, C = B + a, C_1 = B_1 + a + 1,$$

and generally

$$R = Q + P, R_1 = Q_1 + P_1;$$

so that the quotients being given and the first two convergents calculated, the rest can be successfully deduced by a very simple and uniform rule. [CONVERGENT FRACTION.]

The numerator or denominator of a convergent has been called by Sylvester a *cumulant*. (*Phil. Trans.* 1853.) It can easily be expressed as a determinant thus—

$$\begin{vmatrix} a & 1 & 0 & 0 \\ -1 & b & 1 & 0 \\ 0 & -1 & c & 1 \\ 0 & 0 & -1 & d \end{vmatrix}, D_1 = \begin{vmatrix} b & 1 & 0 \\ -1 & c & 1 \\ 0 & -1 & d \end{vmatrix}$$

the law of which is obvious from inspection. A more concise notation for these cumulants is formed by enclosing their diagonal terms between brackets, thus: $D = (a b c d)$. The successive convergents are alternately greater and less than the continued fraction; they oscillate, as it were, from excess to defect with ever decreasing amplitude. Thus the first is greater than F ; the second smaller, but nearer to it than the first; the third again greater, but nearer to F than the second, and so on. The

difference between any two convergents $\frac{P}{P_1}$ and

CONTINUITY, LAW OF

Q_1 is the fraction $\frac{1}{P_1 Q_1}$, since it can be shown that $P Q_1 \sim P_1 Q = 1$. From this it follows that each convergent is in its lowest terms, and that the error committed by taking $\frac{P}{P_1}$ to represent the continued fraction F must be less than $\frac{1}{P_1 Q_1}$, and, therefore, a fortiori less than $\frac{1}{2 Q_1^2}$.

A non-terminating continued fraction whose quotients recur is termed a *periodic* or *recurring continued fraction*. Its value can be shown to be equal to one of the roots of a quadratic equation. On the other hand, every quadratic surd gives rise to an equivalent, periodic continued fraction.

Lord Brounker, president of the Royal Society (1670), appears first to have examined continued fractions, the theory of which was afterwards improved by Dr. Wallis, and many other English and Continental writers. Such fractions have many important applications in the theories of equations and of numbers, as may be seen on consulting the works of Euler, Legendre, Gauss, Dirichlet, &c., or the memoir by Sylvester above cited.

Continuity, Law of. A principle of considerable use in investigating the laws of motion, and of change in general, and which may be thus enunciated: *Nothing passes from one state to another without passing through all the intermediate states.* Leibnitz claims the merit of having first made known this law; but in so far as motion at least is concerned, it is distinctly laid down by Galileo, and ascribed by him to Plato. But though a perception of its truth seems to have been felt long before, Leibnitz was certainly the first who applied the principle to test the consistency of theories, or supposed laws of nature. The argument on which he attempted to establish it a priori is, that if any change were to happen without the intervention of time, the thing changed must be in two different conditions at one and the same instant, which is obviously impossible. A remarkable application of the law of continuity was made by John Bernoulli, in an *Essay on the Laws and Communication of Motion* which gained the prize of the Academy of Sciences at Paris in 1724, to prove that perfectly hard bodies cannot exist; because, in the collision of such bodies, a finite change of motion must take place in an instant, an event which, by the law now explained, is impossible. This conclusion was objected to by D'Alembert and Maclaurin, who on account of it were disposed to reject the law of continuity altogether; but the difficulty is got over by supposing (which on various grounds is extremely probable) that there is no real contact, and that bodies begin to act on each other when their surfaces, or what seem to be their surfaces, are yet at a distance.

CONTINUITY, PRINCIPLE OF

Continuity, Principle of. In Geometry, is a kind of postulate of immense utility as a mode of discovery. According to it any property of a geometrical figure which has been once established will still hold, though it may possibly have to be differently enunciated and demonstrated, through all the successive states through which the figure may be conceived to pass. Thus since two conics which do not intersect in more than two real points may always be projected into two circles, it is obvious that all *descriptive* properties of two circles, e.g. those concerning their centres of similitude, &c., remain true for the projected conics. The property of intersecting, however, being merely *contingent*, or dependent upon position solely, the principle of continuity teaches that two conics which intersect even in four real points, and which, consequently, cannot be projected into two circles, also possess the descriptive properties in question. The works of modern geometers, since the time of Monge, abound in successful applications of this principle, a discussion of which will be found in the writings of Poncelet (*Propriétés Projectives des Figures*), Chasles (*Aperçu Historique et Géométrie Supérieure*) and of several others.

Contorniat. In Numismatics, medals supposed to have been struck about the period of Constantine the Great and his immediate successors; they are of bronze, with a flat impression, and marked with peculiar furrows (Ital. *contorni*, whence their name). They bear the figures of famous emperors or celebrated men. Their object is uncertain; but they have been supposed to be tickets of admission to the public games of the circus in Rome and Constantinople.

Contour (Fr.; Ital. *contorno*). In the Fine Arts, the external lines which bound and terminate a figure. The beauty of contour consists in those lines being flowing, lightly drawn, and sinuous. They must be carefully and scientifically drawn; and this cannot be done without a thorough knowledge of anatomy.

Contouring. In Military sketching, signifies describing on paper the form of any piece of ground, or work of defence, by means of drawing outlines of horizontal sections of this ground or work, taken at some fixed vertical interval from each other.

Contraband (Ital. *contrabando*, *contrary to proclamation*). In Commercial language, goods exported from or imported into a country against its laws. *Contraband of war*: such articles as a belligerent has, by the law of nations, the right of preventing a neutral from furnishing to his enemy. Articles contraband of war are, in general, arms and munitions of war, and those out of which munitions of war are made. All these are liable to be seized: but very arbitrary interpretations have been affixed to the term by powerful states, when able to enforce them by arms. Thus provisions are held contraband of war when it is the object to reduce the enemy to famine. But with respect

CONTRACT

to these and other articles not in their nature contraband, it seems to be the practice that the belligerent should purchase them from the neutral for a reasonable equivalent, instead of confiscating. Despatches from the ambassadors of a belligerent country to their own government, and from hostile governments to consuls in a neutral country, are also deemed contraband; and so are military and some other persons in the service of a belligerent power. (Phillimore's *International Law*, part x. ch. i.)

Contrabasso (Ital.). Usually called in England the *double bass*. The largest of the violin species of string and bowed instruments, of which it forms the lowest bass.

Contract (Lat. *contractus*). In Civil Law, the term usually applied to such agreements, whether express or implied, as create, or are intended to create, a legal right, and corresponding liability; such right not attaching to the possession of the subject-matter of the contract, except in equity, and that indirectly, but subsisting both in equity and law against the contracting party.

The conditions essential to the legal validity of a contract relate either to the competency of the parties, the sufficiency of the consideration or inducement, the nature of the thing contracted for, the fairness of the transaction, or, lastly, to the form of the agreement.

And, first, as to the competency of the parties. The party to be sued must have been at the time of the contract of sound mind, and, unless it was for the supply of necessities, of full age; and if a woman, she must have been unmarried, subject as to the latter condition to some exceptions established either by local custom or by the doctrines of equity.

Secondly, as to the sufficiency of the consideration on the part of the person suing. It must have been either future marriage since performed, or money, or something capable of being estimated in money; or some act, whether of performance or abstinence, whereby some undoubted advantage, though not capable of being exactly valued, accrues to the party sued.

Thirdly, the act contracted for must be neither contrary to written law, nor to public policy; and it must be beneficial to the party seeking either performance or compensation, or to some one on whose behalf he gave the consideration.

Fourthly, there must have been neither fraud (either by concealment or misstatement) nor compulsion on the part of the plaintiff in obtaining the agreement; and fraudulent acts subsequent to the agreement having reference to it are also sufficient to deprive the guilty party of all right under it. Some circumstances are in equity considered either as conclusive evidence of fraud, or as substantive acts of coercion, which are not strictly of such a nature, and are not so deemed at law.

Lastly, as to the form of the agreement. Where it relates to an interest in land of three years' duration or more, or to goods of the

CONTRACT

value of 10*l.* or upwards, unless there be earnest or delivery, or where it is an agreement as surety, or where it is upon marriage as a consideration, it must by English law be in writing; though the want of a written instrument may be supplied in equity by partial performance, that is, by acts evidently done in pursuance of the alleged contract.

Contracts are sometimes implied either in the whole from the acts of the parties, as from the ordering of goods a contract is inferred to pay for them; or in part, and as incidental to the principal agreement, as, in the case of a lease, a contract by the tenant to use fairly and take due care of the thing leased. And at law some obligations not arising in any manner from contract are, as regards the mode of enforcing them, placed on the same footing as those which do arise from contract; the remedy, and not the right, being assimilated by statute.

Such are the general requisites to the validity of agreements; but at law the extent of the right and liability arising under them varies according to their form; agreements being there divided into those under seal, which are called agreements by speciality, and those not under seal, which are called simple contract or parol agreements, including not only such as are merely verbal, but such as are written and unsealed. The first sort alone are binding upon the land, and that only when the heir is named; and they possess this further advantage over agreements by simple contract, that being executed as the *deed* of the contracting party, a sufficient consideration will always be implied in their favour, unless an insufficient one be actually stated on the face of them. Again, agreements both by speciality and simple contract are either to pay a sum certain actually stated in the agreement, or a sum uncertain to depend upon the value of the thing received; or they are agreements to perform certain acts. In the first case, the remedy is by action of debt either on bond or covenant, or upon simple contract, as the case may be. In either of the latter cases the remedy is by action for breach of covenant where the agreement is under seal, or by action of assumpsit where it is by simple contract; the relief given in each of the two last-mentioned sorts of action being compensation in damages for the injury accrued from non-performance of the agreement. [ACTION.]

The remedy in equity, where there is any, is in all cases alike—specific performance of the act agreed to be done; and such relief will be given to the same extent and against the same parties, whether the contracting party himself or his real or personal representatives, without any distinction between agreements under seal and those which are not so.

But though courts of equity have jurisdiction in all cases of agreements, at least in all such as do not constitute an actual debt at law, yet the exercise of that jurisdiction is, subject to certain rules, a matter of discretion; for the

CONTRAGREDIENT

reason that the denial of the equitable relief will not leave the party without some remedy, namely, that of damages at law: and on this account specific performance can only be obtained in equity in those cases where pecuniary damages would not afford to the disappointed party an adequate compensation. Thus such relief will not be granted in any of those cases where the inducement to the bargain or agreement was merely the expectation of profit, as it is in agreements for the sale or purchase of personal chattels; and other circumstances also are a bar to equitable relief, which are no defence to an action at law, as, for instance, the want of mutual liability, apparent laches, and indifference in following up the agreement; or particular consequences of collateral hardships arising to one party from actual performance; or the impropriety in equity of the agreement, as where performance would be a breach of trust. And on the other hand, though the equitable jurisdiction is founded upon a supposed legal right, there are cases in which the right having been lost at law, as by default in literal compliance with the terms of the agreement, will yet be enforced in equity.

CONTRACT, ORIGINAL OR SOCIAL. In Politics, that which is supposed to exist ab initio, according to some theories of government, between the sovereign power and the subject. So prevalent was this doctrine at the period of the Revolution of 1688, that the Convention Parliament pronounced James II. to have broken the 'original contract between the king and the people.' The original contract, with the reciprocity of rights and duties which it engenders, is clearly a supposition having no historical foundation in the annals of any people; but it is, nevertheless, the only hypothesis in which men can consistently proceed in framing a theory of government which shall satisfy at once the moral and economical wants of society.

Contractility. In Physiology, is the power which certain tissues have, during life, of shortening themselves in a peculiar manner: it is usually observed in muscular and some kinds of fibro-cellular tissue; but is also exercised by a series of cells, as in the *Hydra* polype.

Contradictory Propositions. In Logic, are those which having the same terms differ in quantity and in quality. *Contrary Propositions* are two universals with the same terms, the one negative and the other affirmative. [PROPOSITION.]

Contragredient (from Lat. *contra*, and *gradior*, *I go*). Two or more variables are said to be contragredient to as many others when, on replacing those of the first set by linear functions of themselves, those of the second set become replaced by linear functions of themselves respectively inverse (or reciprocal) to the former; in other words, when the new variables, of the one set, bear to the old the same relations that the old do to the new, of the other set. One of the characteristic properties of a set of variables x, y, z, \dots respectively contragredient to ξ, η, ζ, \dots is that the sum of the

CONTRALTO

products $s\xi + y\eta + z\zeta + \dots$ is unaltered by transformation; in other words, this sum is a mixed concomitant of any system of quantities, or a *universal mixed concomitant*. [CONCOMITANT.]

Contralto (Ital.). In vocal Music, the part immediately below the treble; called also the *counter-tenor*.

Contrast (Fr. *contraste*, Ital. *contrastanza*). In the Fine Arts, an opposition of lines or colours to each other, so contrived that the one gives greater effect to the other. By means of contrast, energy and expression are given to a subject, even when employed on inanimate forms. All art is indeed a system of contrasts: lights should contrast with shadows, figures with figures, members with members, and groups with groups. It is this which gives life, soul, and motion to a composition. The very principle of harmony or symmetry, in ornamental art, is contrast, one half of a symmetrical figure being the exact opposite or contrast of the other. Any form, or group of lines without meaning in itself, may become when repeated in reverse, or contrasted with itself, a beautiful form, because it at once acquires the elements of symmetry.

Contratenore (Ital.). In Music, the same as CONTRALTO.

Contravallation (Lat. *vallum, rampart*). In Fortification, an intrenchment formed by the besiegers between their camp and the place besieged, to secure themselves and check the sallies of the garrison. The line of *contravallation* is thus, as the name implies, a sort of *counter* fortification.

Contravariant. Any quantic so derived from a given system of quantities as to be equal, in virtue of any unimodular and linear transformations of its variables, to the quantic derived in the same manner from the system to which the given one is transformed by linear substitutions reciprocal or opposite to the first. Thus

$(bc-d^2, ad-b^2, af-ad, fd-bc, de-cf, \xi\zeta, \eta\zeta)$ is a contravariant of the ternary quadric

$$(a, b, c, d, e, f, \xi, \eta, \zeta)$$

if x, y, z , and ξ, η, ζ be understood to be contragredient sets of facients. [CONTRAGREDIENT.] Geometrically the two quantics represent in trilinear coordinates two reciprocal quadric curves. Any invariant of the system consisting of a quantic

$$(*\xi\xi, \eta\eta, \zeta\zeta, \dots)$$

and a linear function

$$x\xi + y\eta + z\zeta + \dots$$

formed on the hypothesis that ξ, η, ζ, \dots are constants, is a contravariant of the n -ic when these constants are treated as facients contragredient to x, y, z, \dots

Control, Board of, or Board of Commissioners for the Affairs of India. This board was constituted under the authority of Mr. Pitt's celebrated Act, passed in 1783, as a check on the political power of the East India Company, and continued to act until the abolition of that power in 1858.

CONVENTION

Contrôller (Fr. *contrôleur*). An officer appointed to control or oversee the accounts of other officers, and to certify whether the matters confided to his care have been controlled or examined. In England, there are several public functionaries of this title, as the Controller of the Mint, Customs, Stationery, &c.

Contumacy (Fr. *contumace*, Lat. *contumacia*). In Civil and Ecclesiastical Law, a wilful disobedience to any lawful summons or judicial order. The term is in use in the law of Scotland and of France. In that of England it was significant only in connection with EXCOMMUNICATION [which see].

Conus (Lat.). The name of a Linnæan genus of *Vermes Testacea*, characterised by the conical form of the shell, the base of which is formed by the spire, which is accordingly flat, or very slightly projecting; the aperture is narrow and rectilinear, or nearly so, without any enlargement or plication. The genus is retained without subdivision, and forms, with *Pleurotoma*, *Lachesis*, and *Terebra*, the family Conidae of the Pectinibranchiate order of Gastropods in the system of Woodward.

Convent (Lat. *conventus*, from *convenio*, *I come together*). A religious house, inhabited by a society of monks or nuns. [MONACHISM.]

Conventicle (Lat. *conventiculum*, dim. of *conventus*). An assembly for the purpose of divine worship; first used in a contemptuous sense for the meetings of the followers of Wicliffe (stat. 2 Hen. IV. c. 15), and since applied to the places of meeting of petty sects and of Dissenters in general in the Conventicle Act, 16 Ch. II., repealed by 52 Geo. III. c. 155. Originally the word had no such peculiar application, but was used by the fathers and ancient writers for a church.

Convention (Lat. *conventio*). In Political language, this name has been applied to assemblies of national representatives meeting on extraordinary occasions without being convoked by the legal authority. Two parliaments have been so called in English history. The first, that which met in April 1660, and restored Charles II. to the throne—the Lords assembling by their own authority; and the Commons, by virtue of writs issued in the name of the keepers of the liberties of England, by the authority of parliament. The second, that which met in 1688, each house by its own authority and on the summons of the prince of Orange, and declared that King James II. had abdicated the crown, which was transferred to William and Mary. In French History, the name *convention* is applied to that assembly which met after the legislative assembly had pronounced the suspension of the royal functions, in September 1792, and proclaimed the republic at its first sitting. This body dissolved itself on the establishment of the Directory, in October 1796. The Scottish assembly which met on the flight of James II. was entitled the Convention of Estates. In the United States, meetings of the people of separate states by specially chosen representatives, to

CONVENTION

review and amend the state constitutions, have been termed *conventions*.

CONVENTION. In the language of Diplomacy, is generally used as synonymous with *treaty*. Contracts between belligerents as to certain rules to be adopted, on both sides in carrying on the war are technically termed *general conventions*.

CONVENTION, MILITARY. A treaty between military commanders concerning terms for a temporary cessation of hostilities; generally between a victor and a defeated general, for the evacuation of a district or position by the latter. Such, at least, were the two most celebrated conventions of modern times: that of Closter-Seven (1757), between the dukes of Cumberland and Richelieu; that of Cintra (1808), between Junot and the English generals.

Convergent Fraction. The ordinary fraction which is equal to any portion of a continued fraction obtained by neglecting all that follows any particular quotient. Thus, $1, 1 + \frac{1}{2} = \frac{3}{2}, 1 + \frac{1}{2 + \frac{1}{2}} = \frac{4}{3}, 1 + \frac{1}{2 + \frac{1}{2 + \frac{1}{2}}} = \frac{5}{4}$ &c. are three successive convergents of

$$1 + \frac{1}{2 + \frac{1}{2 + \frac{1}{2 + \frac{1}{2}}}} \&c.$$

[CONTINUED FRACTION.] To obtain the numerator (or denominator) of any convergent corresponding to a certain quotient, multiply the numerator (or denominator) of the preceding convergent by that quotient, and to the product add the numerator (or denominator) of the next preceding convergent. Thus $43 = 10 \times 4 + 3$.

Convergent and Divergent Series. An infinite series is said to be *convergent* when, however many of its terms may be added together, the sum never exceeds, numerically, some finite quantity. On the other hand, it is said to be *divergent* when, by adding a sufficient number of terms, a sum can be obtained which numerically exceeds any given finite quantity, however great. A series is not necessarily convergent when its terms continually decrease in magnitude; for instance the series $1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} \&c.$ is divergent. If, however, besides decreasing numerically, the terms have alternate signs, the series will be convergent; thus, $1 - \frac{1}{2} + \frac{1}{4} - \frac{1}{8} \&c.$ is convergent. A series will be convergent if the quotient obtained by dividing each term by the preceding one is numerically less than some assignable proper fraction, or if this property obtains from and after a certain term. On the other hand, the terms being all of the same sign, the series will be divergent if the quotient in question is equal to or greater than unity. This test of convergency and divergency cannot be always applied, however, and recourse must be had to others. For instance, the ratio of the n^{th} to the $(n-1)^{\text{th}}$ term of the series $1 + \frac{1}{2} + \frac{1}{4} \&c.$ being $\frac{n-1}{n}$,

is always less than 1, but no proper fraction can be assigned than which it is always less, for it approaches unity without limit as n increases. The series is, in fact, divergent; for the third and fourth terms are together greater than $\frac{1}{2}$, the four following terms are

CONVEYANCE

greater than four times the last or $\frac{1}{8}$, the eight following terms are together greater than $\frac{1}{8}$, and so on, so that the whole series has a greater sum than $1 + \frac{1}{2} + \frac{1}{4} + \&c.$. . . which is manifestly divergent. For further details on this subject, see Cauchy's *Cours d'Analyse*; *Penny Cyclopædia*; *Encyclopædia Metropolitana*, art. 'Calculus of Functions'; Catalan's *Traité Élémentaire des Séries*, Paris 1860, &c.

Convergent-nerved. In Botany, a term used in describing the venation of leaves, to denote cases where the ribs form a curve and meet at the point, as in *Plantago lanceolata*.

Converse of a Proposition. In Mathematics, is another proposition which has for its hypothesis and predicate, respectively, the predicate and hypothesis of the original proposition. Thus the converse of Euclid's fifth proposition, first book, wherein it is affirmed that if two sides of a triangle be equal, the opposite angles will also be equal, is, If two angles of a triangle be equal, so also will be the sides opposite to these angles. The converse of a proposition is not necessarily true, and consequently requires demonstration. Euclid generally establishes his converse propositions indirectly, that is to say by a *reductio ad absurdum*.

Conversion (Lat. *conversio*). In Logic, a proposition is said to be *converted* when the terms are so transposed that the subject is made the predicate, and vice versa. All logical conversion is illative; i.e. the truth of the converse follows from that of the original. Conversion is either *simple* or *per accidens*. Universal negatives (denoted by the sign E) and particular affirmatives (I) can be converted simply, retaining both quantity and quality: thus, 'No virtuous man is a rebel'; 'No rebel is a virtuous man.' Conversion per accidens changes either quantity or quality. Universal affirmatives (A) are converted by changing the quantity; as, 'All oaks are trees'; 'Some trees are oaks.' Particular negatives (O) are converted by changing the quality, considering the negative as attached to the predicate instead of the copula; the proposition is thus changed into I, 'Some poets are not learned'; 'Some not learned (unlearned) men are poets.' [PROPOSITION.]

Convert. A person who changes his religion. Persons, of what faith soever, who abandon their own creed and embrace Christianity are called *converts*, in contradistinction to *apostates*, applied generally to *Christians* who adopt another religion.

Convex. [CONCAVE AND CONVEX.]

Conveyance (from *convey*). In Law, a deed which passes land from one to another. [REAL PROPERTY, LAW OF.] A *conveyancer* is a lawyer whose business consists in advising and preparing such deeds. It is not necessary to be called to the bar to practise as a conveyancer; but most conveyancers take that step soon after beginning their business, and frequently combine it with that of equity draftsmen.

CONVICTION

Conviction (from Lat. *convincere*). At Common Law, is the finding of one guilty of an offence by the verdict of a jury; and may take place where one is outlawed, or appears and confesses, or is found guilty on the inquest. [JURY; VERDICT.] By various statutes summary proceedings, without the intervention of a jury, are authorised for the trial and conviction of minor offenders. Such are those before commissioners of excise, &c., for breaches of the revenue laws, and before justices of the peace for various disorderly offences. The party charged must be summoned to attend; and a conviction by a magistrate must be in writing, but need not (as formerly) state the evidence for and against the defendant.

Convocation (Lat. *convocatio*). In English Ecclesiastical Law, the council of the church, derived, first, from the custom of the bishops assembling their diocesan clergy for the sake of considering spiritual matters; and, secondly, of the archbishops holding convocations of the clergy of a whole province. Convocations were first assembled in England under the king's authority by Edward I., who summoned them by their provinces, for the sake of obtaining subsidies from the clerical body. They met in each province in two houses—one, of the suffragan bishops; the other, of deans, archdeacons, and representatives of the inferior clergy. The taxation of their own body was withdrawn from convocation in 1664; and, on the other hand, the privilege of voting for knights of the shire was then conceded to ecclesiastics. As the power of enacting canons had been already virtually abolished by statutes of Henry VIII., Elizabeth, and Charles II., there now remained no business for convocation to transact; and it was only in the reigns of William III. and Anne, when attempts were made by the high church party to impart fresh activity to it as an ecclesiastical tribunal, that its meetings were attended with any historical importance. After that period it became customary to prorogue convocation every year immediately upon its assembling. Within the last few years it has become the practice for the crown to allow convocation to sit and transact business for some days at the commencement of every session of parliament. Committees have been appointed for reporting upon church grievances or abuses, and their reports and recommendations have been discussed in both houses. No legislation has hitherto issued from these proceedings. The rights and history of the convocation are treated of at length in several writings of the learned Bishop Gibson, especially his *Synodus Anglicana*, Lond. 1702.

CONVOCA-TION; HOUSES OF. In the university of Oxford, is the assembly which ratifies decrees and statutes. It is composed of all members of the university who have at any time been regents (RECTOR), and who, if independent members, have retained their names on the books of their respective colleges. No

CONVULSION

proposition can be entertained in convocation unless it has been first submitted to the Hebdomadal Council, or Congregation, by whom it must be in the first instance sanctioned or rejected.

Convulsions (from *convolutus*, part. of *convolvere*, *I roll together*). In Anatomy, the winding folds of the superficial layer of the brain; and also the coils and turns of the intestinal tube.

Convolvulaceæ (*Convolvulus*, one of the genera). A natural order of herbaceous or shrubby Exogens, twining and producing a milky juice when wounded. They are very abundant in the tropics, and possess purgative qualities in their roots, depending upon a peculiar resin, of which scammony and jalap, yielded by the *Convolvulus Scammonia* and *Eragonium Purga*, may be taken as examples. Many of these plants are objects of striking beauty. Some, which unfold their pure, white, magnificent flowers at night only, are called in tropical countries *Belle de Nuit*; others expand only beneath a warm and brilliant sunshine. The *Lignum Rhodium* of the old pharmacologists is produced by an upright bushy species, called *Convolvulus* or *rhiza scoparia*. They belong to the Solanaceæ alliance, and have monopetalous corollas, five free stamens, a basal placenta, and leafy doubled-up cotyledons.

Convo-y (Fr. *convoyer*, *to conduct*). In Navigation, the term applied to designate a ship or ships of war, appointed by government, by the commander-in-chief on a particular station, to escort or protect the merchant ships proceeding to certain ports. Convoys are mostly appointed during war; but they are sometimes also appointed during peace, for the security of ships navigating seas infested with pirates. For an account of the various regulations and conditions relative to convoys, see *McCulloch's Com. Dict.*

Convor. In the Military service, signifies a detachment of troops appointed to guard supplies of provisions, ammunition, or money, in their progress to a distant part of any country, or to an army in the field, against an attack which might be made upon them either by the peasantry or by parties of the enemy.

Convulsion (Lat. *convulsio*, from *convellere*, *I pull together*). A writhing and agitation of the limbs, and involuntary action of the muscles in general. The fits vary much in extent and violence, sometimes attacking the whole body, and at others confined to particular parts; in the former case the mind is affected, but in the latter it often remains undisturbed; they also vary in duration, lasting from a few minutes to some hours. They are sometimes preceded by dizziness, double or disturbed vision, and coldness, and are followed by great languor; but at others they come and go without much disturbance. Teething, worms, and overloaded bowels are common causes of convulsive attacks in children; and these are relieved by freely and timely lancing the gums, and by the adminis-

COOLER

tration of proper purges. In *puerperal convulsions*, bleeding and opiates are the usual remedies; and in cases where convulsive attacks arise from violent affections of the mind, the exciting causes must be studiously avoided. Warm baths, bleeding, and nerrine stimulants are the usual medical aids; and where there is difficulty of swallowing, a glyster, composed of half a pint of gruel with a drachm of tincture of opium and two drachms of tincture of assafetida, has, in adults, proved eminently useful. Cold affusions often do harm. The after-treatment consists in the judicious use of tonics and nervous stimulants, and in avoiding all obvious exciting causes.

Cooler. An apparatus used by brewers and distillers for cooling worts. The coolers generally consist of very shallow vessels exposing great surface, and placed in the high and airy parts of the brewery; the cooling is sometimes assisted by fans, which agitate the air over their surfaces. Worts are also occasionally cooled by causing them to traverse metal pipes, which are surrounded by a counter-current of cold water.

Cooperation. The association of two or more persons in some industrial process. If the labour undertaken is of the same character, as that of two men sawing timber, the cooperation is said to be *simple*; if the parties are engaged in different occupations, all of which, however, tend to one result, as is the case with the very numerous workmen who contribute towards the manufacture of a watch, the cooperation is called *complex*. It is by such a cooperation that the division of labour is made most effectual.

Of late years this word has been employed in a different but analogous sense: viz. for the association of workmen and others, either for the purpose of distributing commodities in the manner of retail trade, or for actual manufacture. The latter is becoming very common in Continental towns: the former has been successfully attempted in the north of England; and in some cases workmen have associated with a view to engaging in production.

In cooperation of this kind, capital and labour are united in the same persons. The capital is subscribed by the workmen, and the subscriber works in the occupation for which the capital is employed. Or in case the capital is employed for trade, a fixed sum is generally paid as interest on the amounts subscribed, and the remaining profits are divided according to the evidence of consumption. Generally the purchaser of articles at a store or shop of this description receives a tally or token; and when a division of profits takes place, can claim out of the accumulations a sum proportioned to the number of tokens or tallies produced. In almost all cases, the rule is to give no credit for goods supplied.

The association at Rochdale known by the name of 'the Equitable Pioneers,' is that which is most commonly cited as one of the earliest and most successful of these com-

COORDINATES

binations. The origin of the scheme was the failure of the local savings-banks. It is said that, beginning with a wheelbarrow full of goods, the business done at this 'store' in 1864 reached nearly 200,000l.

Cooperative societies are in general looked on by economists and philanthropists with a very favourable eye. The system appears likely to harmonise, or at any rate to throw great light on the mutual and apparently conflicting interests of labour and capital, and ultimately to form a practical refutation of some among the worst features in the action of trades unions and other combinations of workmen and employers more or less coercive and irritating. The moral effects of such associations are more obvious. They inculcate economy, freedom from indebtedness, and the best forms of self-respect and honest independence. Nor are they less useful (the cooperation taking the form of retail trade) in obviating the practice of adulterating commodities which we are told prevails to so serious an extent among many shopkeepers, especially those whose business lies chiefly with working people. As the dealers are also the buyers, the interests of honesty are thus on the side of the shop, and the motives to adulteration are eliminated. No man would willingly sell himself inferior, disguised, or unwholesome commodities.

It is not quite clear whether the cooperative system can be made to apply to production with as much safety and success as it does to consumption. There is greater complication in the business, more risk of mismanagement, and the necessity arises of adopting the credit system of ordinary business. But the experiment has been tried and has not hitherto failed. It is acknowledged that on the Continent the success has been continuous, and that the condition of the workmen has been materially improved where the system is adopted. Similar testimony is given on the whole to the working of cooperation for production in this country, in so far as its effects have hitherto been estimated.

Cooperative Stores. [COMBINATION.]

Coordinates (Lat. *con, together, and ordinis, I arrange*). In Algebraic Geometry,

the system of magnitudes by which the position of a point is determined. Of the many systems of coordinates now in use, the most important are distinguished as *Cartesian* (rectangular and oblique), *polar*, *trilinear*, *triangu-*

COORDINATES

lar, quadriplanar, tetrahedral, three-point, four-point, elliptic, spherical, &c.

In the *Cartesian system*, the invention of which by Descartes marked one of the greatest epochs in the history of mathematical science, two fixed right lines or *coordinate axes* are assumed; one of which XX' is usually distinguished as the *abscissa axis* and the other YY' as the *ordinate axis*; the point O in which they intersect is termed the *origin of coordinates*, the coordinates themselves, of any point in the plane, being the lengths of the segments intercepted upon each axis between the other axis and a parallel to the latter through the point in question. To distinguish between the four points M_1, M_2, M_3, M_4 , which according to this would have the same coordinates, the latter are regarded as positive or negative according as the corresponding intercepts fall on one or the other side of the origin. The intercept on the abscissa axis OX is called the *abscissa* of the point in question and denoted by x , that on the ordinate axis OY its *ordinate* and represented by y . Innumerable points may be found whose coordinates will satisfy any given equation in x and y . The curved line on which all such points lie is called the *locus of the equation*, and the latter in its turn is termed the *equation to the curve*. If the equation is of the first degree in x and y , the locus is a right line; if of the n^{th} degree, every right line will cut the locus in n points; in other words, the latter will be a curve of the n^{th} order. To render the equations homogeneous, and thus secure greater symmetry, the coordinates x and y are frequently expressed as ratios $\frac{x}{a}, \frac{y}{b}$ where a may be regarded as the symbol for the linear unit.

In a similar manner to determine a point in space by the *Cartesian system*, three fixed lines OX, OY, OZ (*coordinate axes*) meeting in a point O (the *origin*), and determining three distinct planes XOY, YOZ, ZOX (*coordinate planes*) are assumed, and the coordinates of any point are the intercepts, positive or negative, determined on each axis by two parallel planes, one of which passes through the other two axes, and the other through the point in question.

Polar Coordinates.—In this system a fixed *initial line* or *polar axis* OX is assumed, one extremity O of which is called the *pole*. The *polar coordinates* of any point M in the plane are then the *radius vector*, $OM = r$ or distance of the point from the pole, and the *vectorial angle* $MOX = \theta$, which latter is regarded as positive or negative according to the direction in which the initial line must rotate in order to coincide with the radius vector. To determine a point in space by means of polar coordinates, it is necessary to assume as fixed elements a *pole* O , an *initial line* OZ through the pole, and an *initial plane* OZX through this line. The *polar coordinates* of any point M are then the *radius vector* $MO = r$, the *plane vectorial angle*

$MOZ = \theta$, and the dihedral angle ϕ between the *vectorial* and *initial planes* MOZ, XOZ .

Trilinear Coordinates of a point M are the lengths α, β, γ of the perpendiculars let fall from the point upon the sides, opposite to the angles A, B, O of an assumed and fixed *fundamental triangle* or *triangle of reference*. It is to be observed that the trilinear coordinates of every point in the plane satisfy the relation

$$\alpha a + \beta b + \gamma c = 2\Delta,$$

where a, b, c, Δ represent, respectively, the sides and area of the triangle of reference. In virtue of this relation all equations may be rendered homogeneous, and thereby all the advantages of symmetry secured in the analytical treatment of geometrical questions.

Triangular Coordinates of a point in a plane are the ratios to the triangle of reference of the three triangles which have its sides for bases, and the given point for common vertex. The triangular coordinates x, y, z of any point in the plane obviously satisfy the relation

$$x + y + z = 1.$$

Quadriplanar Coordinates of a point in space are the lengths $\alpha, \beta, \gamma, \delta$, of the perpendiculars let fall from that point upon the faces, opposite to A, B, C, D , of a fixed *fundamental tetrahedron* or *tetrahedron of reference*. The quadriplanar coordinates of every point in space will satisfy the relation

$$A\alpha + B\beta + C\gamma + D\delta = 3V,$$

where V is the volume of the tetrahedron of reference, and A, B, C, D the areas of its faces.

Tetrahedral coordinates of a point in space are the ratios to the tetrahedron of reference of the four tetrahedra which have the faces of the former for bases and the point in question for common vertex. The relation

$$x + y + z + w = 1$$

is satisfied by the coordinates of every point in space.

Tangential Coordinates.—In the Cartesian system a point is determined by its coordinates x, y , and a line by any linear relation between these coordinates, such as

$$\xi x + \eta y + z = 0,$$

or rendered homogeneous by putting for x and y the ratios $\frac{x}{s}, \frac{y}{s}$,

$$\xi s + \eta y + z = 0.$$

In the tangential system, on the other hand, a line is determined by two coordinates, and a point by a linear relation between the same. In fact the above plane is perfectly determined by the ratios ξ, η, z , which denote, in fact, the

reciprocals, taken negatively, of the intercepts on the axes between the origin and the line in question. It can easily be shown that if η, ξ, z satisfy any linear homogeneous equation, the corresponding lines will all pass through a point whose Cartesian coordinates x, y, z are proportional to the coefficients of that equation.

COORDINATES

Thus according as x, y, s or ξ, η, ζ are regarded as variable,

$$\xi + \eta + \zeta = 0$$

may be interpreted as the Cartesian equation of a line whose tangential coordinates are ξ, η, ζ or as the tangential equation of a point whose Cartesian coordinates are x, y, s . Just as in the Cartesian system a homogeneous equation of the n^{th} degree in x, y, s represents a curve of the n^{th} order, since by the theory of equations there are n values of x, y, s which simultaneously satisfy this equation and that of any line

$$\xi + \eta + \zeta = 0,$$

so in the tangential system a homogeneous equation of the n^{th} degree in ξ, η, ζ represents a curve of the n^{th} class, since there are, in general, n distinct values of the coordinates ξ, η, ζ which satisfy, simultaneously, the equation in question and that of any point

$$\xi + \eta + \zeta = 0.$$

From the foregoing the meaning of tangential coordinates in space will be at once evident.

Three-point Coordinates of a line are the lengths of the perpendiculars α, β, γ , let fall upon the line from the vertices A, B, C of the fundamental triangle. Between the coordinates α, β, γ of any line whatever exists the relation

$$\alpha^2 \beta^2 + \beta^2 \gamma^2 + \gamma^2 \alpha^2 - 2\alpha\beta\gamma \cos A - 2\alpha\gamma \alpha \cos B - 2\alpha\beta \alpha \cos C = 4\Delta^2,$$

where $\alpha, \beta, \gamma, A, B, C, \Delta$ represent the sides, opposite angles, and area of the fundamental triangle.

Four-point Coordinates of a plane are the lengths of the perpendiculars from the vertices of the fundamental tetrahedron upon that plane.

Elliptic Coordinates.—Through any point in a plane two, and only two, quadrics confocal with a given one can be drawn, and conversely two quadrics confocal with a given one may be said to determine, by their intersection, the position of any point in the plane.

Two such quadrics, one of which is always an ellipse and the other a hyperbola, are of course defined by the magnitudes of their respective major-axes; so that the latter may be said to determine the position of a point on the plane. These major-axes, or suitable functions of the same, are termed for this reason the elliptic coordinates of the point in question. In a similar manner the elliptic coordinates of a point in space are the major-axes, or certain functions of the same, of the three quadrics confocal with a given one which intersect in that point. Thus, whatever value λ may have, the quadric

$$\frac{x^2}{a+\lambda} + \frac{y^2}{b+\lambda} + \frac{z^2}{c+\lambda} = 1$$

will be confocal with

$$\frac{x^2}{a} + \frac{y^2}{b} + \frac{z^2}{c} = 1,$$

and the three roots of the cubic equation in λ will determine the three confocal quadrics, an ellipsoid and two hyperboloids, which intersect

COPAL

in the point (x, y, z) . These three values of λ are usually considered as the elliptic coordinates of the point in question. [CONFOCAL QUADRICS.] In pure and applied mathematics the use of elliptic coordinates often secures elegance, simplicity, and symmetry. In every good treatise on algebraic geometry and the calculus, therefore, full details will be found. The subject has been recently treated with great skill by Hesse in his *Vorlesungen über Analytische Geometrie des Raumes*, Leipzig 1861.

Elliptic coordinates are themselves merely particular cases of far more general systems, where, for instance, a point in space is defined by the values of three parameters which determine the three individuals, of as many systems of given surfaces, which intersect in that point. The choice of the three systems of surfaces will depend, of course, upon the nature of the investigation.

Spherical Coordinates.—Points on a sphere may obviously be determined in a similar manner to those on a plane; arcs of great circles in the former case taking the place of segments of right lines in the latter. To each system of coordinates in a plane will correspond therefore a system of coordinates on a sphere; these are called *spherical coordinates*.

Coordinates, Transformation of. The passage by algebraic substitution from one system of coordinates to another is frequently required in geometrical investigations, and the formulae necessary for so doing are, in the cases of ordinary coordinate systems, given in all treatises. The general method pursued is to establish a sufficient number of equations by whose solution the coordinates of a point in one system may be expressed as functions of the corresponding coordinates in the other. Thus the passage from Cartesian to trilinear coordinates is effected by means of the system of linear equations,

$$\begin{aligned} a_1x + b_1y + c_1z &= \alpha, \\ a_2x + b_2y + c_2z &= \beta, \\ a_3x + b_3y + c_3z &= \gamma, \end{aligned}$$

where the equations obtained by putting the trilinear coordinates $\alpha = \beta = \gamma = 0$ are the Cartesian equations, rendered homogeneous, of the sides of the triangle of reference in the trilinear system.

Copaiba or Copivi Balsam. An exudation from the *Copaifera officinalis*, a South American tree; it is a liquid resin, and yields by distillation a considerable quantity of a pungent volatile oil. It is used in medicine chiefly as a diuretic.

Copal (an American name applied to clear gums). This substance is often improperly called *gum copal*. It is a peculiar resin, very difficultly soluble in alcohol; hard, brittle, and inodorous: its specific gravity varies from 1.04 to 1.13. It is the produce of the *Rhus copallina*. Brazilian Copal is the product of several

Indians. Indian Copal is produced by *Faleria indica*. Another kind of copal is also brought

COPALINE

from the coast of Guinea. It is used varnishes.

Copaline or Highgate Resin. A fossil resin found in irregular pieces of a brown colour, resembling copal. It was originally discovered in the London clay of Highgate Hill.

Coparcenary (Lat. con, and particeps). In Law, an estate is said to be held in coparcenary, the tenants being termed *coparceners*, where it descends from an ancestor to two or more persons. Sisters are coparceners at common law; tenants in gavelkind by common law in Kent, and by the *custom of the manor* in some other localities. No right of survivorship exists between coparceners. They may agree, or anyone may force the rest to make partition.

Copernican System. The system of Astronomy propounded by Copernicus. It affirms the sun to be at rest in the centre, while the planets revolve round it. [ASTRONOMY; PROLAMAIO SYSTEM.]

Copernicia (after Copernicus the astronomer). Tropical American palms, with tall stems and fan-shaped leaves. *C. cerifera*, the Carnaúba Wax Palm of Brazil, has a very hard trunk, forty feet high and six or eight inches thick, commonly employed for building purposes. The young leaves are coated with wax, called *Carnaúba wax*, harder than bees-wax and of a lemon tint, which has been employed for candle-making.

Copiapite or Yellow Copperas. A hydrated sesquisulphate of iron, occurring in the district of Copiapo in Chili. [FERRUGINITE.]

Coping. In Architecture, the upper covering, or top course of a wall, usually of stone, and wider than the wall itself, in order to let the rain-water fall clear of the wall: in brick walls the coping is often executed with a course of plain tiles, and brick laid upon it on edge and bedded in cement.

Copper (Lat. cuprum; Ger. kupfer). This metal was known at a very remote period; and in the early ages of the world, before iron was in use, copper was the chief ingredient in domestic utensils and instruments of war. It is an abundant metal, and is found native, and in many ores; of these the most abundant are the varieties of *pyrites*, which are sulphides of copper and iron. The richest British mines are those of Cornwall, but it is also abundantly produced in North and South America, in Australia, and elsewhere. A mass of native copper weighing 500 tons is said to have been found in the mines of Lake Superior. Copper is distinguished by its colour. Its specific gravity is 8.9. It is ductile and malleable, and requires a temperature somewhat lower than gold, but higher than silver (estimated somewhat above 2,000° Fahrenheit) for its fusion. Exposed to air and moisture, copper gradually becomes covered by a green rust; when heated red hot, it absorbs oxygen, and is superficially converted into a black oxide, which is the basis of the principal salts of copper: it consists of 32 copper and 8 oxygen. It forms

COPPERAS

blue or green salts with the acids; of these the *sulphate of copper*, or blue vitriol, is a good example. The salts of copper are poisonous; and in consequence of the use of copper vessels for culinary purposes, food is sometimes contaminated by them. It is detected when in very minute quantities by the bright blue colour produced by the addition of liquid ammonia, and by a brown precipitate with ferrocyanide of potassium. A clean slip or wire of iron dipped into a solution containing copper becomes covered with the latter metal, in a metallic state.

Commercial copper is never perfectly pure, but almost always contains traces of silver, arsenic, and bismuth, which interfere more or less with its malleability and ductility. Among the alloys of copper, those with tin (bronze and bell metal) and with zinc (constituting the varieties of brass) are the most important. Standard gold and silver are also alloys of these metals with copper.

Copper Glance or Vitreous Copper-ore. A native disulphide of the metal, containing when pure about 80 per cent. of copper.

This ore occurs massive and crystallised in six-sided prisms. Its colour is grey with a metallic lustre; but the surface is sometimes dull, or iridescent. It is sectile and breaks with a conchoidal fracture.

Copper Glance is one of the richest ores of copper, and forms veins and beds together with Copper Pyrites, Malachite, &c.

Copper Nickel. Native di-arsenide of nickel, composed of about 60 per cent. of arsenic and 40 nickel, with small quantities of antimony, cobalt, lead, iron and sulphur. It occurs crystallised and massive. The colour is copper-red. It emits an arsenical odour when struck with steel; and breaks with a conchoidal fracture.

Copper Pyrites or Yellow Copper-ore. A double sulphide of copper and iron, composed of about 35 per cent. of sulphur, 35 of copper and 30 iron.

It occurs crystallised in tetrahedrons, and stalactitic, mammillated, and amorphous. When pure, the colour of a newly fractured surface is bright brass-yellow with a metallic lustre. Frequently the surface displays variegated tarnish; it is then called *Peacock-ore*.

Copper Pyrites occurs in lodes or beds, with other ores of copper, lead, and iron, in rocks of various geological ages, but generally in primary and metamorphic rocks. It is the most abundant ore of copper in England.

Copper Schaux or Copper Froth. [TYROLITE.]

Copper Slate. [KUPFER-SCHIEFER.]

Copper Uranite. [CHALCOLITE.]

Copper Vitriol. [CYANOSITE.]

Copperas or Green Vitriol. Hydrated protosulphate of iron, composed of 28.9 per cent. of sulphuric acid, 25.7 protoxide of iron, and 45.4 water. This salt, which is largely manufactured for commercial purposes, also occurs *native*, and is generally produced by the

decomposition of Iron Pyrites. It is used in dyeing, and in the manufacture of writing-ink, Prussian blue, &c. It effloresces when exposed to air; absorbs oxygen, and becomes of a reddish colour, whence the French term, *Cuivreuse*, corrupted into *copperas*.

Coppice (Old Fr. *coppes*). Woods which cut down at stated periods to be manufactured into poles, rods, stakes, faggots for fuel, bark for the tanner, or charcoal. When wood of this kind has no standard trees, it is called simply a *coppice* or *coppes wood*; but when it has standard trees interspersed through it, it is called a *wood*. When coppices are cut down for hoops, rods, and small stakes for manufacturing into crates, hoops, wicker hurdles, &c., the period at which they are cut varies from six to ten years, according to the soil. When they are cut down for poles for hops and similar purposes, the periodical cuttings are commonly between twelve and fourteen years apart; and when they are cut down chiefly for the sake of the bark, they are seldom cut oftener than from fourteen to twenty-one years. A country abounding in coppice wood generally abounds also in singing birds, which are comparatively rare in countries where all the woods are of the pine and fir tribe.

Coprolite (Gr. *κόπρος, dung*; *λίθος, a stone*). The fossil excrement of animals. This name, given originally by Dr. Buckland to certain deposits which he discovered in the lias and determined to be the fecal remains of the gigantic saurians of that period, has since become universally applied in consequence of the discovery of other large deposits of similar material in rocks of various ages. The true coprolites of the lias are like kidney potatoes, but of black or ash-grey colour, earthy texture, and glassy fracture. They are twisted, showing the mark of the intestine, and have been evidently voided of different degrees of hardness. They are generally accumulated in heaps in particular parts of the deposit.

Besides these coprolites of the lias, phosphatic nodules bearing the same name, but far more abundant, have been found below the chalk in various parts of England, and also in the crag beds of Suffolk. The former are in an earthy state, semi-indurated, and the latter stony.

The value of these minerals is derived from the phosphate of lime of which they are partly made up, and which is used with great advantage as mineral manure, after having undergone a cheap chemical treatment. In all parts of the country where either the crag or the upper greensand is found at the surface, search is now being made for this coprolite bed, and if found there is no want of candidates to purchase and utilise it. It is usually converted into a soluble superphosphate by the action of sulphuric acid; but in whatever form it is applied, it constitutes a valuable manure.

It is now many years since certain fancied flints in the crag of Suffolk were proved by Professor Henslow to contain animal matter, and their special value was soon proclaimed;

but it was not till long afterwards that the yet more valuable accumulations were found in the greensands of Cambridgeshire and Sussex. The trade is now of great importance, and the production very large. The crag specimens yield, when washed and powdered, about 56 per cent. of phosphates, and are obtained from various places in Suffolk. The total yield in 1861 was estimated at about 10,000 tons. At present (1864) it is estimated at not more than from 2,000 to 3,000.

The greensand varieties are rougher externally, but yield as much as 60 per cent. of phosphates, and are more soluble than those from the crag. The principal localities are in Cambridgeshire and Hertfordshire. The annual yield is from 30,000 to 40,000 tons.

These coprolites contain from 4 to 5 per cent. of organic matter and a little silica; out from 70 to 80 per cent. of their whole substance is a mixed phosphate and carbonate of lime.

Coprophagans, Coprophaga (Gr. *κόπρος, dung*, and *φάγω, I eat*). A section of Lamellicorn beetles which live in and upon the dung of animals.

Copula (Lat. *a bond or tie*). In Logic, that part of the proposition which affirms or denies the predicate of the subject. The only true logical copula is the present tense of the verb *to be*, with or without the negative sign, 'is' or 'is not.'

Copy (Fr. *copie*). In the Fine Arts, a transcript from an original work of art. When an artist copies his own work, it is called a *duplicate* or *replica*.

Corr. In Printing, is the subject-matter to be printed, whether it be an original work in manuscript or a reprint: in the first case it is termed *manuscript copy*, or written copy; in the second, *printed copy*.

Copyhold. In Law, is a species of *customary estate*, said to be held by copy of court roll; i. e. where the tenant's title is evidenced by a copy of the rolls of a manor made by the steward of a lord's court. Customary estates are those which exist in real property subject to the custom of manors; and their peculiar characteristic is, that all alienations of them must be transacted, in part at least, in the lord's court, the ordinary mode of alienations being by surrender to the lord and admittance of the new tenant. The peculiar tenure called *copyhold* is derived from the tenure in *villain socage*, as it was termed, held formerly under a manor. This was in its origin a mere permissive tenure by serfs attached to the soil; and copyhold estates are still expressed in legal vocabulary to be held 'at the will of the lord by the custom of the manor.' With respect to the incidents of dower, and other characteristics, they are frequently governed by the custom of the manor; but where this is not the case, they are under the same rules which govern the transmission and alienation of freehold property. By the Reform Act, copyholders for life, or a greater estate to the amount of 10l. per annum, are admitted to the exercise of the

COPYRIGHT

electoral franchise in counties. The enfranchisement of copyholds has been promoted by various statutes, of which the latest is 21 & 22 Vict. c. 94 (1858). Its provisions are administered by the Copyhold Commissioners.

Copyright. In Law, the right of property in a literary composition vested in the author. By 64 Geo. III. c. 156, s. 4, the term of copyright in an author and his assignee extended to twenty-eight years absolutely, and for the life of the author if he survived that period. But by the 5 & 6 Vict. c. 45, the duration of all copyrights, whether the author be dead or alive, was extended to *forty-two* years; and it further provided, that if the author be alive at the expiration of this period of forty-two years from the publication of his works, he shall enjoy the copyright to his death, and that his heirs or assignees shall enjoy it for seven years after that event. A book of registry is kept at Stationers' Hall. The author of assignee of a pirated work has his remedy by action. The Act requires that five copies of every work should be delivered at the expense of authors and publishers, on demand in writing, for the use of a few favoured public and private libraries in the United Kingdom. In France, copyrights continue for twenty years after the death of the author. In most of the German states, they are perpetual; and a copyright secured in one state is good in all. Both in England and on the Continent, various other compositions, such as engravings, etchings, prints, photographs, maps, charts, sculpture of all kinds, and designs for articles of ornament and utility, receive from statute a protection analogous to that of literature.

Copyright, International. International copyright has been introduced as yet only to a very limited extent between civilised nations. The German Diet framed a convention on the subject between its own members in 1837. The crown has power under 7 & 8 Vict. c. 12 (1845) to allow foreign authors privilege of copyright. In 1846, Great Britain entered into treaty with Prussia; in 1847, with Hanover; in 1861, with France; in 1864, with Belgium.

Coquilla Nut. The seeds of *Attalea funifera*, a South American palm. They are much used in turnery.

Coquimbite or White Copperas. A hydrated tersulphate of iron found in a felspathic rock, in the province of Coquimbo, in Chili. It appears to have been produced by the weathering of Iron Pyrites.

Coracite. An amorphous variety of Pitchblende, found in the syenite of the north coast of Lake Superior.

Coracle (Welsh, *cwrwg*). A boat made of wicker-work covered with leather, still commonly used in Wales.

Coracoid (Gr. *κορακοειδής*, like a crow). A name first applied to a small process of the blade-bone of apes and man, on account of its resemblance to the beak of a crow; and now extended to a large flattened bone passing from the shoulder-joint to the sternum in birds,

CORAL ISLANDS

reptiles, and monotremes, and of which the process above mentioned is the rudimental representative.

Coral Islands (Gr. *κοραλλίων*, coral). In various parts of the ocean, but chiefly within the tropics, there are islands and groups of islands or long lines of reef rising to low-water mark, which are due entirely to the labour of the coral animal, and are among the most striking of the phenomena that connect organic with inorganic nature.

Coral reefs are usually of a form approaching to the circular, and the water is shallow in the centre, but surrounded by a very deep and even unfathomable sea. When the reef is so high as to remain nearly dry at low water, the animals leave off building; and then the rim or edge of the great basin becomes covered by calcareous sand, which offers a foundation for the growth of marine vegetables, and afterwards a resting-place for the seeds of trees and plants cast upon it by the waves. Trunks of trees also, carried by rivers from continents and islands, after their long wanderings are often pitched ashore; and sometimes carry with them small animals, such as lizards and insects, which become the first inhabitants of the new island. The Pacific Ocean, throughout a space comprehended between the thirteenth parallels of latitude on each side of the equator, is a great nursery of coral islands; as are also the Arabian and Persian gulfs. Between the coast of Malabar and that of Madagascar there is a great sea of coral. Flinders describes an unbroken reef 350 miles long upon the coast of New Holland; and between that country and New Guinea coral formations extend throughout a distance of 700 miles, interrupted by no intervals exceeding 30 miles in length. The growth of coral seems, when compared with human epochs, extremely slow; but the facts just cited show that they have produced results of no mean importance, as influencing the general aspect of the earth's crust. Their circular form, the steep angle at which they plunge into the sea, and the countries in which they occur, render it probable that they are the crests, as it were, of submarine craters; and occasionally lava, and volcanic rocks have been found in their central lagoons, which have generally a deep narrow passage, kept open by the efflux of the ocean at low tides. Such

Whitsunday Island in the Pacific, with its enclosed Lagoon.

openings are almost always on the leeward side, the windward side of the islands being more complete and perfect than the other. Owing to this fortunate circumstance, ships can enter and sail out with ease; indeed, the safety of many of these harbours is entirely

CORAL ORE

dependent upon this cause. It would to arise from the large masses of coral rock that are thrown up by the waves on the windward side. These rocks are probably subject to elevations and depressions connected with volcanic agencies. Perhaps the carbonate of lime, which is the building material employed by the busy little architects of these islands, is partly derived from calcareous springs issuing into the sea from fissures in the volcanic bottom. There is, however, an inexhaustible supply in sea-water itself. The following sections illustrate the peculiar mode of growth of coral:—

Section of a Coral Island.—*a a* the habitable part,
b b the lagoon.

Section of a Coral Island upon a large Scale.—*a b* the habitable part; *b c* slope of the side; *c c* parts of the lagoon; *d d* knolls of coral.

Coral formations are among the oldest and the newest rocks that come under the notice of the geologist. The ancient limestones of the Silurian and Devonian periods, the vast masses of carboniferous limestone underlying the coal measures, the limestones of the coral rag, and many others of secondary age, with those at present in course of formation in many parts of the world, are all essentially the same. The species of coral are no doubt different, but the general resemblance of a group of the larger building species is wonderfully perfect. In most of the fossil reefs the limestone is much more compact than in those of recent date; and the interstices are partly occupied by drifted shells and fragments of smaller species. They are partly filled also by subsequent metamorphic action and the infiltration of carbonate of lime.

Coral Ore. A variety of Hepatic Cinabar found at Idris in Carniola. It consists of curved lamellar concretions, with the form and apparent structure of fossil shells.

Coral Rag. A remarkable deposit consisting almost entirely of large corals resembling the kinds found in modern coral reefs. This bed occurs in the upper part of the middle division of the oolitic group in England. It is about forty feet thick, and large portions of it are frequently made up of one species of coral. It is also full of fragments of shells mixed with and occupying interstices between the corals. The typical coral rag is chiefly confined to Wiltshire, near Calne and Steeple Ashton; but it is imperfectly represented in Yorkshire.

Corallina. A name applied by Linnaeus to a genus or group of marine organised bodies of arborescent habit, with jointed stems, supported on a kind of root, divided into branches, which are likewise jointed. Neither pores nor polypes are distinguishable on the surface of these beings; their chief purpose in the economy of nature is to prepare during life, and

CORIANDER

precipitate by their decay, fine particles of carbonate of lime or chalk: they thus lend their aid to the Lithophytous corals in covering submerged land with the elements of a fertile soil, which the expansive subterranean forces may afterwards convert into dry land.

Corallines. The name commonly applied to the tubular or nudibranchiate order of Polypes which have an external jointed calcareous or horny covering: the true nature of these plant-like animals was discovered by our countryman Ellis. [TUBULIFERA.]

Coran. [ALCORAN.]

Corbells (Fr. corbeau). In Fortification, small gabions. [GABIONS.]

Corbel (Fr. corbeau). In Architecture, a projecting bracket often sculptured like a modillion, sometimes in the form of a basket, for the purpose of supporting a superincumbent object, or for receiving the springing of an arch. A corbel table is a projecting battlement, parapet, or cornice, resting upon a series of corbels.

Corculum (Lat. dim. of *cor*, the heart). An old name for what botanists now call the embryo of a plant.

Cordate (Lat. *cordatus*). In Botany, a term used in describing the general form of organs, to denote anything having two round lobes at its base, the whole resembling the heart in a pack of cards; as the leaf of *Alnus cordifolia*.

Cordellera. The monks of the Franciscan order are so called, from the cord or girdle which they wear round the waist. They were originally called Friars Minor, or Minorites.

This name was also assumed by one of the Parisian political clubs, which numbered Danton and Marat among its members. [JACOBINS.]

Cordiaceæ (Cordia, one of the genera). A natural order of arborescent Exogens, inhabiting the tropics of both hemispheres. They are nearly allied to *Convolvulaceæ*, from which they are separated by their inverted embryo and drupaceous fruit. They are sometimes associated with *Boraginaceæ*; but their plaited cotyledons and dichotomous style serve to distinguish them. The flesh of the fruit is succulent, as seen in the Sebesten plums, the produce of the *Cordia Myxa* and *C. Sebestena*; but otherwise they are of no value. It has been asserted that the wood from which the mummy cases of the Egyptians are made was that of *Cordia Myxa*; but there is no doubt that it was really produced by *Sycomorus antiquorum*, formerly called *Ficus Sycomorus*.

Cordierite. A mineralogical synonym for iolite.

Cordon (Fr.). In Fortification, the coping of the escarp or inner wall of the ditch. It is usually rounded in front, and projects one foot over the masonry. A line of troops drawn round a town or tract of country, so as to prevent ingress or egress, is also called a cordon.

Coriander (Gr. *korivros*). The seed of the *Coriandrum sativum*. This plant is a native of Europe, and is cultivated on account of its

seeds, which are occasionally used in medicine; they have a peculiar perfumed flavour, with some bitterness, and form one of the ingredients of *curry powder*.

Coriariaceæ (Coriaria, the only genus). A natural order of shrubby Exogens, inhabiting Chili, Peru, the south of Europe, and a few other places. It is placed by De Candolla directly after *Ochnaceæ*, a member of the Rutal alliance, with which it agrees in some respects, but from which it differs essentially in being apocarpous. Some botanists consider them apetalous, and allied to *Phytolaccaceæ*; but the question of their affinity is still unsettled. Their sensible properties are of a poisonous nature.

Corinthian Order. In Architecture, one of the five orders. The capital is a vase elegantly covered with an abacus, and surrounded

3

by two tiers of leaves, one above the other; from amongst which stalks spring out, terminating at their summits in small volutes at the external angles of the abacus, and in the centre. The capitals of the Tuscan, Doric, and Ionic orders appear to be added to the tops of the columns; but the Corinthian capital seems to grow out of its shaft. The height of the column varies from $9\frac{1}{2}$ to $10\frac{1}{2}$ of the

diameter; and the capital from $1\frac{1}{2}$ to 1 of the same dimension; the latter being their height in the celebrated example of the temple of Vesta at Tivoli. The entablature of this order is variously decorated. The architrave is usually profled with three fasciæ of unequal height; though in some examples there are only two. The frieze is often sculptured with foliage, and the cornice decorated both with modillions and dentils: the former having a sort of baluster front with a leaf under them; and the latter, which are cut into the body of the band, being occasionally omitted, as are sometimes even the modillions. Among the principal remaining examples of the order at Rome, are the temple of Mars Ultor, the temple of Jupiter Stator, the portico of Severus, and the Pantheon; the temple of Vesta at Tivoli is a good example of the order slightly modified. The Tower of the Winds and the Choragic monument of Lysicrates at Athens are the only specimens of the Corinthian order, not being Roman work, to be found in Greece. [ARCHITECTURE.]

Corium (Lat.). In Anatomy, is the basis of the skin, or *true skin*, and consists of a vascular and fibro-cellular tissue, of interlaced dense, but elastic, filaments. It rests on the

subcutaneous cellular tissue, and is covered by the cuticle or *scarf skin*.

Cork (Ger. kork, Span. corcho). The bark of the *Quercus Suber*, a species of oak growing in the southern provinces of Spain, France, and Italy. When rasped cork is digested in water and alcohol, it leaves from 70 to 80 per cent. of insoluble matter, which has been called *suberine*, and which by the continued action of nitric acid is converted into *suberic acid*.

Corm (Gr. κόρυς, a trunk or stem). In Botany, a short roundish bulb-like underground stem, solid and not scaly; as in the Crocus and Gladiolus.

Corn. The seeds of certain grasses which have been immemorially used as food, for man or animals, are called *corn*; and those which are used exclusively or principally by man are called *bread corn*. The term is also sometimes applied to the seeds of other plants which may be ground into meal and used as food, such as the seeds of the buckwheat, the quinoa, and of certain leguminous plants, which, however, are more properly denominated *pulse*. The principal bread corns of temperate climates are wheat, rye, oats, and barley; those of warm climates are maize, rice, and millet; and those of cold climates, oats and barley.

Value of the Produce of Corn.—In agricultural countries, not in a very high state of civilisation, the culture of corn is the principal employment of the great bulk of the community; and in all considerable countries, how far soever they may be advanced in arts and refinement, its culture is always by far the most extensive as well as the most important branch of national industry. No great country, perhaps, ever existed, the population of which was so extensively engaged in manufactures and commerce as that of Great Britain. Still, however, we employ about a quarter of our inhabitants in agriculture; and of these, fully three-fourths are directly or indirectly engaged in the raising of corn. Unfortunately, there are no accounts, on which it would be safe wholly to rely, of the ordinary produce of corn, either in this or any other great country. But, without pretending to peculiar accuracy, we are inclined to think that the present (1866) average growth of all sorts of corn in the United Kingdom may be safely estimated at about 70,000,000 quarters, of which about 62,000,000 may be consumed by man and the lower animals. Now supposing this estimate to be nearly accurate, and taking the average price of the different descriptions of corn at 30s. a quarter, the total value of the corn annually produced will amount to the sum of 100,000,000*l.* sterling, quite sufficient to evince the paramount importance of agriculture as a source of wealth as well as a means of subsistence.

Corn-Laws.—This superior importance of corn as an article of culture, and the dependence so generally placed upon it as an article of food, are the causes why the trade in it has been so very generally subjected to regulation. It is long even before the most enlightened portion

CORN

of an instructed community become satisfied the advantage of permitting the supply of corn or any indispensable article to be adjusted like that of less important things, by the unfettered competition of private individuals.' It seems, at first sight, reasonable to suppose that the most likely way to secure plenty at home is to impose restrictions on exportation; but in truth and reality, this is very far from being the case. However fertile it may be, no country that imposes restrictions on exportation need hope to escape perpetually recurring scarcities for wherever free exportation is prevented, the excess of supply that occurs in plentiful years, being thrown wholly upon the home market, depresses prices to such an extent as to be ruinous to the farmer; and thus, by injuring agriculture and lessening the quantity of the land in corn, never fails to occasion a scarcity on the occurrence of a deficient harvest. In Great Britain, however, the policy has long been to give every facility to exportation, and even to lay restrictions on importation. This has arisen from our legislature being principally composed of individuals dependent on and connected with the land; and whose interest consequently has led them to endeavour to secure as high a price as possible for its produce. But it is needless to add that this policy is, if possible, even more objectionable than the other. Instead of being publicly advantageous, high prices are, in every instance, distinctly and completely the reverse. The less the sacrifice of money or of labour for which corn or any other article can be procured, so much the better. But to make sure that the price of corn, or of anything else, will be fixed at the lowest limit at which the required supply can be obtained, all that is necessary is to abolish all restrictions, whether on exportation or importation. Freedom is the parent of abundance, cheapness, and equality of price; restriction, of scarcity, dearth, and uncertainty. Any interference with the trade in corn, or with any other great department of trade, that has not the removal of natural or artificial restraints for its object, is not only inconsistent with the best established principles, but is sure to be pernicious. In this, as in all other things connected with national industry, the short and only safe rule is to leave individuals to pursue their own interest in their own way.

Our limits forbid our attempting to make any enumeration of the various statutes that have been passed at different periods for regulating the trade in corn. Down to the Revolution, the policy was to restrict exportation; but from that period the contrary policy has been pursued, and the legislature has pretty uniformly endeavoured to facilitate exportation, and to prohibit or fetter importation. It was not, however, till about 1770 that the restrictions on importation began to have much practical influence. But about that time, population having begun rapidly to advance in consequence of the extraordinary impulse given to manufacturing industry by the inventions

and discoveries of Watt, Arkwright, Wedgwood, and others, the price of corn in England began to rise above its price on the Continent; and from being an exporting we became an occasional, or rather a pretty constantly, importing country. Had there been no restrictions on importation, our prices, it is plain, could not have exceeded those of the adjoining Continental states by a greater sum than might have been required to defray the cost of importing into this country. The restrictions, however, overturned this natural principle; and in deficient years added materially to the difference between our prices and those of the Continent.

At the close of the war, in 1814 and 1816, the renewed intercourse with the Continent led to a great importation of corn, which occasioned a sudden and heavy fall of prices, productive of much severe distress amongst the farmers. Parliament endeavoured to obviate this by increasing the restrictions on importation; a device which had, in part, the anticipated effect. But since 1820, the influence of improved communications and of ameliorations in agriculture has been so very great, that, notwithstanding the vast increase of population, prices have been progressively falling, and were, in 1836, lower than in any previous year since 1787. Practically, therefore, the influence of the restrictions was materially diminished, and a much greater effect was usually ascribed to them in ordinary years than they really exerted. No doubt, however, they tended materially to aggravate the scarcity and suffering originating in a deficient harvest, and were, therefore, very mischievous to the public; and as inducing great fluctuations in price at all times, they were a serious inconvenience to the farmer.

But despite these defects the corn laws might have maintained their place on the statute-book indefinitely. It is true that they were assailed by the highest authorities on political economy, and were attacked by the formidable organisation of the leaders in the free-trade movement. But, like many other protective schemes, they seemed to offer a security, or at least an advantage, to a particular class of persons, and were therefore clung to with great tenacity. But the unsatisfactory corn harvest of 1846 and the failure of the potato crop of that year made it necessary to adopt extraordinary measures for making good the deficiency in the supply of food. Under the circumstances the suspension of the corn laws could hardly have been avoided. But if once suspended, their re-enactment would have been all but impossible; and it was better, by it once providing for their repeal, to make an end of the system, and of the dissatisfaction and agitation to which it had given birth, than to endeavour to continue it in any modified shape. Such was the view of the matter taken by Sir Robert Peel, and he fortunately succeeded, notwithstanding the most formidable opposition, in carrying the Act 9 and 10 Vict. c. 22, which provided for the immediate

CORN

modification of the corn laws, and for their final abolition on February 1, 1849. From that period all varieties of corn, with meal, flour, &c., have been admitted to consumption under the all but nominal duties, the former of 1s. a quarter, and the latter of 4½d. a cwt.

Rate of Production in England, and Amount of Imports.—There is no doubt that the agricultural produce of this country has increased largely in quantity during the present century, and still more largely when its amount is contrasted with that derived from the soil by ancient systems of agriculture, and in the middle ages. We know that Sicily was considered the granary of ancient Rome, and yet Cicero tells us that the amount of produce was, in very favourable years, ten times the seed sown, and in a fair average year eight. It could be proved incontestably by existing documents, that the same, or even a less rate, characterised the agriculture of this country in the thirteenth and fourteenth centuries, and that, consequently, imports being insignificant or uncertain, the population maintained on the soil could not have exceeded two millions, and probably did not equal one million and a half.

Agricultural science has not only made it possible that the actual return to the seed should reach sixteen, twenty, and, in some cases, thirty and thirty-five times, but by the discovery of certain processes has, even under the supposed discouragement of corn cultivation by the cheapness of imported grain, certainly enlarged, and perhaps doubled, the area devoted to cultivation. The ancient system of agriculture, to which deep ploughing, efficient draining, and artificial manures were unknown, necessitated, in order to reinvigorate the soil, frequent fallows. Our forefathers were unacquainted with root crops: the turnip, the swede, the carrot, and the mangold being of comparatively recent introduction. One of the purposes which these roots fulfil is the fertilisation of the soil for grain crops; another is the possibility of keeping large stocks of sheep and cattle, and of at once supplying the market with meat, of diminishing the time at which stock is ready for sale to one-third of that which was required of old, and of furnishing an enormous increase of natural manures. Concurrently with these improvements in agriculture, the breeding of stock has, in consequence of the care devoted to selection, become almost an exact science, and the clumsy and unprofitable sheep, pigs, and cattle of our forefathers have been replaced by herds carefully chosen for their symmetry and fitness, the breeder giving all his attention to the purpose of producing the greatest possible result at the least possible cost. Again, our forefathers were constrained to be content with natural grasses only, whereas modern science has been able to appropriate, by means of careful observation and judicious experiment, a multitude of foreign or artificial grasses, the produce of which is more certain and more abundant. Lastly, mechanical appliances have been largely employed in agriculture. Hand-

sowing has been generally superseded by drilling, the steam-engine has taken the place of the flail, the reaping and mowing machine are rapidly being employed for harvest labour, and it is likely that before long the steam plough will be generally adopted. In short, the cultivation of corn, instead of being carried on as of old by rude implements and imperfect experience, is now either directly or indirectly connected with and dependent on mechanical science, chemistry and even physiology; and consequently an enormous increase of absolute production is achieved at a diminishing cost.

It is not possible to determine with any precision the amount of the grain produce of this country. With an obstinacy seriously disadvantageous to their ultimate, and probably to their immediate interests, the landowners and tenant farmers in England have resisted the proposal to collect agricultural statistics, on the plea that such enquiries would be inquisitorial and vexatious. But if so, the inquisition and vexation is inflicted and endured with patience, and even thankfulness, by other trades. Merchants and manufacturers are glad to know the amount of foreign produce at present in the market, or available for sale; and they are possessed of all such information to the full. Nay, the quantity of those commodities which seem to compete most notably with the possible profits of the British farmer, corn and wool, with what is annually imported and what is held for consumption, are known to the quarter and the pound, while the amount of British produce can only be guessed at. It is almost needless to say, that when buyers are ignorant or ill-informed of the quantity of the commodity available for sale, the greatest inconveniences are experienced from fluctuations in market prices.

The imports of grain have latterly been extremely large, indicating that, considerable as has been the improvement in agriculture, the gross amount is insufficient for the demands of the population. The annual import of wheat and flour of wheat, reckoned together, which amounted in 1845 to 315,615 quarters, and in 1846 to 2,962,928 quarters, varied between 3 and 6 millions of quarters per annum between 1847 and 1859. In 1860 it exceeded 7,000,000, in 1861 it exceeded 8,000,000, and in 1862 it amounted to 11,528,445 quarters—more than ten-fold what it was in 1845. And the annual importation of other kinds of grain and meal has also increased during the same period. Varying in general from 4 to 5 millions of quarters between 1846 and 1859, it exceeded 7,000,000 in 1860-61-62.

Although, however, we are not able to determine with any degree of precision the amount of cereal produce in Great Britain, the figures supplied by the comptroller of the corn returns as to the amount of wheat and flour imported into the United Kingdom enable us to determine with some accuracy the annual deficiency.

In the three years 1860-1-2, the amount far exceeded the quantity imported in any previous

CORN

year. These harvests were known to have been very scanty, and by far the largest portion of the foreign supply reached this country from the western portion of the United States. Indeed, the dependence of this country on the regular transmission of grain from these regions is nearly as complete as that of the cotton

in the southern part of the same regions, and of far greater significance both from an economical and political point of view.

There do not appear to be any reasonable grounds for the alarm entertained by some economists, as to the cessation or straitening of supplies of grain from foreign countries. The corn-producing regions of Western America are almost boundless, and the facilities of transit keep pace with the occupation of the soil. The country is traversed by vast navigable rivers, and the people rapidly construct railways and canals for the purpose of traffic. The town of Chicago, the entrepôt of the corn trade, increased its population from 30,000 in 1850 to more than 100,000 in 1860, and is still progressing at the same rate. A rise of a few shillings in the market price of wheat in England makes it advantageous to export the produce of many farms, which cannot yet, in consequence of the cost of carriage, secure a profit at a lower price. And while the soil is boundless, its fertility is astonishing. It is a common thing for the same field to be cropped with Indian corn for twenty years successively, and this without the application of a particle of manure, and without apparently any diminution in the amount produced. Cargoes of wheat of the finest quality have even been imported from California by the Cape Horn passage.

The great increase of consumption in the article of foreign corn does not necessarily indicate that the general produce of the United Kingdom has fallen. It only proves that by reason of abundant foreign supply the people are better fed. Nor is this the only advantage. A well-fed people has always more means in its power for the consumption of other commodities; for it is clear that the demand for commodities other than necessities of life will always be in proportion to the margin left over after these exigencies are satisfied. Plenty of food, then, if it does suggest that the profits of the agriculturist are diminished in one quarter, is equally demonstrative of the fact that his profits are enlarged in another, and that the general consumption of the people is proportionately increased. This inference, which may be established on purely abstract grounds, is verified in fact by the increased value of real property, and the notoriously general rise in rents.

It may be observed that wheaten bread has been the customary food of the English people from the earliest times. This kind of grain is, as far as quantity goes, the least productive of all cereals, needs soil of good quality for its growth, and requires careful preparation in order that the produce may be remunerative.

Hence a scarcity of wheat makes a resource to other kinds of grain possible, and interposes a considerable distance between want and famine. Far different was the case with the Irish before the failure of their staple crop. In that country the peculiar occupancy of land, among many other causes, led to absolute dependence on the potato for subsistence. When this crop failed, the people could get no other food, because they had subsisted on the cheapest kind procurable. Hence the extreme distress of the Irish famine.

Information as to the average annual price of wheat in England has been supplied by official authority since the year 1583. At this period, the result of the great additions to the currency, consequent upon the discovery of large and very productive mines of silver in South America, was beginning to be generally felt, and was producing serious effects on fixed rents and payments. The purpose of the statute was to determine a portion of these rents into wheat and malt, and returns of the highest price at which these commodities were sold on particular days in the year were ordered to be registered in the principal market towns. For those of an earlier date than that at which the subjoined table commences, the reader is referred to Lloyd's *History of Corn Prices*. Trustworthy information on the period preceeding 1583 is, however, still a desideratum in economical history.

Account showing the Quantities of Foreign and Colonial Corn, Flour, &c. entered for Consumption in the United Kingdom in each of the Thirty-four Years ending with 1863. (Compiled from Parliamentary Papers.)

Years	Wheat and Flour	Barley	Oats and Oatmeal	Rye

Cornaceæ (Corns, one of the genera). A small natural order of epigynous Exogens, of the Umbellal alliance, formerly associated with *Caprifoliaceæ*, but now separated on account of their polypetalous structure. They are known by their two (or more) celled fruit without a double epigynous disc, their tetramerous flowers, valvate corolla, and opposite leaves without stipules. Some North American species of *Cornus* are valuable as tonics.

Cornbrash. A member of the lower part of the great oolitic series of England, made up of rotten impure limestone decomposing into a good wheat soil. [BRASH.]

Cornua (Lat. *horny*). The transparent membrane of a horny texture which forms the anterior part of the eyeball. In vertebrates it is simple: in insects it is subdivided into numerous hexagonal segments.

Cornet (Ital. *cornetta*, a small flag). A commissioned officer in the cavalry, corresponding in rank with the ensign of infantry. The standard used to be carried by the cornet—hence the name of the latter—but is now carried by a troop sergeant-major.

Cornett. In Music, a shrill wind instrument formed of wood, which appears to have been in use in the earliest times, and remained so till about the commencement of the eighteenth century, when it was displaced by the oboe.

Cornet-à-Pistons (Fr.). A brass wind musical instrument, of the French horn species, but capable of much greater completeness of scale and perfection of intonation from the valves and stoppers (pistons) with which it is

CORNUA

furnished, and whence it derives its name. The tribe of instruments to which this belongs has of late years been much improved, principally by Messrs. Sax of Paris, and Messrs. Distin of London. There are now four or five grades of instruments of this class, which take different parts respectively, forming, in the whole, a perfect band of themselves, and capable of playing almost any kind of music. The cornet-à-pistons is the treble instrument, and there are others for the alto, tenor, baritone, and bass parts, gradually increasing in size, but all on the same general construction. They are much used for military bands, and for music played in the open air.

Cornice (Fr. *corniche*, Ital. *cornice*). In Architecture, the upper great division of an entablature [ENTABLATURE], consisting of several members.

Cornin. A bitter crystalline matter obtained from the bark of the *Cornus florida*.

Cornish Diamonds. Transparent colourless Rock Crystals found in Cornwall.

Corns. Thickenings of the cuticle of the toes, of a horny texture, arising from continued pressure over a projection of bone. One of the best and simplest remedies for this painful disorder is to wear upon the toe or part affected a piece of leather, spread with diachylon or other emollient plaster, and having a hole in it corresponding with the size of the corn. By this means all pressure upon the corn is avoided. (Sir B. Brodie's *Lecture on Corns and Bunions*, *Medical Gazette*, Feb. 13, 1836.)

Cornstone. The lower member of the old red sandstone, or middle Palaeozoic series of rocks, as developed in Herefordshire and the adjoining counties. The name was given from the fertility of the soil derived from this rock, which there consists of a mixture of sandstones and impure concretionary limestones, readily decomposing into a good material for all the corn crops. These cornstones repose on imperfect flags, some of which are extensively quarried.

Cornu Ammonis (Lat.). A name sometimes applied to the fossil shells called Ammonites.

Cornua (Lat.). In Zoology, hard and more or less elongated processes projecting from the head. [HORN.] The term is usually applied to such processes in the class Mammalia, in which they serve as weapons of offence and defence. These weapons consist either of bone, when they are called *antlers*; or of horn, or of bone and horn, or lastly of bone and hairy skin. The first kind of horns are peculiar to the deer tribe; the second to the rhinoceros; the third to the sheep, ox, and antelope tribes; and the fourth to the giraffe. The bony horns, antlers, cerata, or *cornua solida*, as they are technically termed, during the whole period of their formation resemble the horns of the giraffe, inasmuch as they are covered with a hairy and highly vascular integument: the bony material of these processes is in fact secreted by the vessels of that integument, so that their coexist-

CORNUA

ence is essential as long as growth proceeds. When their growth is completed, and the antlers have arrived at their characteristic size and figure (which in the elk and Wapiti deer are truly remarkable), the determination of blood to the parts gradually lessens; the vessels shrink; the circulation in the formative membrane is at length suppressed; and the tegument then shrivels, dries, cracks, and is rubbed off by the instinctive actions which the deer now almost ceaselessly performs with his newly acquired and consolidated antlers. The skin and periosteum of the head, once continuous with those of the antler, now terminate at an abrupt line at the base of the antler, from which a ridge of bone, or *burr*, as it is termed, is developed, apparently for the purpose of defending the margin of the persistent integument; for when this is continued, as in the Muntjac deer, half-way up the antlers, the burr is developed immediately above its termination, or at the middle, and not at the base of the antlers. Some physiologists have conjectured that the use of the *burr* was to compress the vessels of the periosteum of the antler, and that its formation was deferred to near the completion of the antler; but observation shows that it commences at an earlier period of growth; and sound physiology teaches that the cessation, like the commencement, of the growth of the horn, must be the result of deeper and more constitutional operations. The most remarkable fact in the economy of antlers is that they are shed and renewed annually, the fall of the horns being concomitant with the shedding of the hair. The attempts to assign the final cause of this phenomenon have not been very successful. In the axis deer, e.g., the bucks do not all shed their horns at the same time, but at different periods of the year. In the reindeer the branches which project forwards from the base of the horn, or the brow antlers, are habitually used to scrape away the snow which conceals the lichens on which they principally feed. The female, therefore, needs antlers as much as the male, and she has them; but this is a rare and singular exception, for the females of other species of deer are destitute of these ornamental weapons. True horns, or those which consist either partly or entirely of horny material, are never shed. In the antelopes they are in almost all cases confined to the male, and their bony basis is generally solid; in sheep and oxen the horns are commonly present in both sexes, and the bony basis is hollow. The term *cornua cava* is, however, usually applied to all horns consisting of bone and horn, and reciprocally the ruminants having such horns are termed *hollow-horned*. But this extension of the term seems to have arisen from a consideration of the external horny sheath alone, which is but a part, and that not the most essential, of the horn. The horn or horns of the rhinoceros consist of an agglutination of horny fibres, which are attached only to the integument; the integument adhering with more than usual firmness at this part

COROLLA

to the roughened surface of the bone beneath. The horn of the rhinoceros differs from that of other mammals in being situated upon the median line of the forehead; so that when there are two, they are placed one behind the other, and not laterally and symmetrically, as in the ruminants.

A few ruminants have naturally two pairs of horns; and this was the case with a great extinct species, *Sivatherium*, whose remains have been discovered in the Himalayan mountainous regions, where the small *Antelope quadricornis* still exists. Horns are characterised in zoological descriptions according to their position, as *Cornua nasalia*, *frontalia*, *parietalia*, &c.: or according to their direction, as *Cornua prona*, turned forwards; *reclinata*, turned back; *incurva*, bent inwards; *vara*, bent outwards; *redunca*, with the apices curved forwards; *lyrata*, when they represent the horns of the ancient lyre; *gyrata*, when spirally twisted: or according to their period of existence, as *Cornua perennia*, when they last the lifetime of the animal; or *Cornua decidua*, or *annua*, when annually shed: lastly, horns are termed *Cornua ossea*, *Cornua solida*, *cava*, according to their structure, as above described. For the peculiarities of the giraffe's horns, see GIRAFFE.

Certain species of many other classes have parts projecting from the head, analogous in form or structure to the cornua of the mammalia. The frontal protuberance of the emu, horn-bill, and helmeted curassow consists of bone covered with a sheath of horn; the kamichi or horned screamer is a still more remarkable example of a bird so armed. In reptiles we find horned toads, vipers, and iguanas. Fishes present divers simulations of true horns. In mollusca retractile feelers or eye-stalks are commonly called *horns*, as in the snail; but the appendages which would come under the general definition of our present term arrive at their maximum relative size, variety, and singularity of form in the class of insects.

Cornucopia (Lat. *cornucopia*, *horn of plenty*). In the Fine Arts, an ornament representing a horn, from which issue flowers, fruits, leaves, and the like. The fable accounting for the origin of this emblem of Plenty, is that Amalthæa, when one of her goats had broken off a horn against a tree, presented it to the infant Zeus (Jupiter) wreathed with flowers and filled with fruit. The cornucopia is found very frequently in the types of ancient coins, particularly upon those of Sicily. (See the medal of Arsinoe.)

Cornwallite. An amorphous arsenate of copper found in Cornwall.

Corolla (Lat. *a garland*). That envelope of a flower which is placed next within the calyx. It is usually more richly coloured and larger than the latter, but is extremely variable in this respect. Owing to its being in many plants one of the most striking parts of the flower, it is much employed by botanists in their systematical arrangements, and by the French school

COROLLARY

has been taken as the means of forming fundamental characters of the subclasses in the great Dicotyledonous division; but there is no doubt that its importance for this purpose has been much overrated. Theoretically considered, the corolla is composed of modified leaves, with the ordinary organisation of which its parts or petals correspond as much as can be expected of rudimentary organs. Its physiological action is to absorb oxygen, without decomposing carbonic acid, in which respect it agrees with leaves in their morbid state in the autumn.

Corollary (Lat. *corolla*, dim. of *corona*, *crown*). In Mathematics, denotes any consequence immediately deducible from the demonstration of a proposition. All the corollaries in our editions of Euclid have been inserted by editors; they constitute, in fact, so many new propositions differing from the original ones merely in the fact that the demonstrations have been omitted. Had Euclid thought fit to make a greater demand on the intelligence of his readers, many of his propositions might assuredly have been given as corollaries.

Corona (Lat.). In Architecture, the flat, square, massy member of a cornice, very frequently called the drift or larmier; its situation is between the cymatium above and the bed-moulding below, and its use is to carry the water, drop by drop, from the building.

CORONA. An appearance seen round the sun in total eclipses of that body. [Sun.]

Corona or **Coronet**. This word is employed by botanists to express certain appendages of the corolla, which are arranged within it in a circle. In the *Narcissus* it is a cup; in *Symphytium* it consists of five glandular processes; in *Asclepias* it is a thick fleshy ring extended into bended lobes. In all cases the coronet is a modification of sterile stamens.

Corona Australis and **Corona Borealis** (Lat. the *southern crown* and *northern crown*). Two of the old constellations of Ptolemy; the first in the southern and the second in the northern hemisphere.

Corona Dentis (Lat.). In Zoology, the exposed part of a tooth, which projects beyond the alveolus and gum.

Coronamen (Lat.). In Zoology, the superior margin of a hoof, called in veterinary surgery the *coronet*.

Coronary (Lat. *coronarius*, *relating to a crown*). Coronary vessels and ligaments are those which spread round certain viscera, bones, &c.

Coronation. [King.]

Coroner (Lat. *coronator*). Is the title of an office established before the Norman Conquest, of which the holder was, as his name indicates, in a peculiar manner the officer of the crown, whose private rights of property, whether arising by escheat, wardship, or consisting in demesne, it was his business to maintain and superintend in the county for which he acted. Connected in some degree with this character is the more important if not the sole function which he now exercises: that of holding inquests on the

CORPORATION

bodies of such as either die or are supposed to die a violent death (4 Edw. I. st. 2); for which purpose he is empowered to summon jurymen out of the neighbourhood, and witnesses. Should violent death be occasioned by any personal chattel, it was forfeitable as a deadland to the crown until the abolition of deadlands by 9 and 10 Vict. c. 62. The coroner was originally in some sort the colleague and assistant of the sheriff, and in his default might still act as sheriff in the execution of writs, which in such case would be directed to him. The county coroner is still, as the sheriff was formerly, elected by the freeholders of the county. Generally there are four or six for each county; and coroners may now also be appointed for districts in their counties. Borough coroners are also appointed in towns having quarter sessions. Coroners are remunerated by fees under Acts of Parliament.

Coronet (Lat. *corona*). In Heraldry, an inferior crown belonging to the British nobility. The figure of John of Eltham, second son of Edward II., who died in 1334, affords the earliest representation of this ornament. Barons do not appear to have borne them earlier than the reign of Charles II. The time at which the coronets of the present orders of nobility were respectively distinguished in the existing fashion cannot be ascertained.

Coronet-bone. The second of the consolidated phalanges of the horse's foot.

Corporal (Ital. *caporale*, from *capo*, *the head*). A non-commissioned officer in the army, next in rank to a sergeant. He is distinguished by two chevrons or stripes worn on the arm.

Corporal Punishment. In the Army, is inflicted on the bare back with a cat-o'-nine-tails. It is limited in amount to fifty lashes, and, by a rule lately made, every soldier is exempt from liability to it until by gross misconduct he forfeits that exemption; and even after thus forfeiting his right to exemption he is liable to corporal punishment only for grave offences, while one year's good conduct restores him to his original position.

Corporation (Lat. *corpus*, *body*). A body politic or incorporate; consisting of a person or persons having power to take and grant, &c., on himself or themselves and their successors. Corporations, in English Law, are divided—

1. Into sole and aggregate. Sole corporations are such as consist of a single person who is constituted a corporation by law, for the purpose of enjoying certain advantages and incurring certain duties, transmissible to his successors. Such is the person of a living in respect of his benefice; a bishop, in respect of his ecclesiastical rights and property of his see; the king, &c. Corporations aggregate are such as consist of more individuals than one, and are kept up by a perpetual succession of members. 2. Into ecclesiastical and lay. Parsons, bishops, deans, and chapters are instances of the former. The latter are

CORPORATION

again subdivided into civil and eleemosynary. Among the first are trading companies and municipal corporations; among the latter, hospitals, colleges in the universities, and similar establishments (which, however, were anciently esteemed ecclesiastical).

By the law of England, corporations are erected only with the king's consent, express or implied; and may exist by prescription, by letters patent, or by Act of Parliament. Bishops, parsons, &c., may indeed be said to exist as corporations by force of the common law; but some ancient municipal bodies, such as the corporation of London, are in a stricter sense corporations by prescription. Corporations by Act of Parliament may be created either expressly or by implication; as, where a body is to take lands by succession, this constitutes them a corporation. But the ordinary mode by which they are erected is by the king's letters patent or charter of incorporation; persons exercising the power of founding corporations by a grant of their own (as the chancellor of the university of Oxford) being for this purpose only delegates of the king.

The chief incident of a corporation is the power of taking by succession. This power is, however, confined in the case of sole corporations to estates of freehold; corporations aggregate only can take goods and chattels by succession. Grants by a corporation aggregate must be by deed under their common seal, which is necessary to give validity to most of their acts. A corporation has essentially the power of making by-laws to bind its own members, which are valid so far as they are not contrary to the laws of the kingdom. Corporations ecclesiastical and eleemosynary may, moreover, be subject to rules or statutes imposed by the king or the founder; civil corporations only to the common law and their own by-laws. In aggregate corporations, the act of the majority is the act of the whole.

The common law capacity of corporations to take lands has been, however, materially narrowed by statute. Thus a devise of lands to a corporation by will is bad, unless in some exceptional cases. And, in consequence of the Statutes of Mortmain [MORTMAIN], a corporation, whether lay or ecclesiastical, must now have a license from the crown in order to purchase.

All corporations are said to be subject to visitation. The visitor of ecclesiastical corporations is the ordinary [ORDINARY]; the visitor of lay corporations is the founder. In eleemosynary corporations this right, therefore, is in the founder and his heirs, or in such person as he has appointed: in civil corporations, the king is visitor, and exercises that jurisdiction in the King's Bench; where alone misbehaviour of such corporations or their officers can be enquired into, chiefly by means of the processes termed *MANDAMUS* and *QUO WARRANTO* [which see]. A corporation is dissoluble—1. By Act of Parliament; 2. In the case of an aggregate corporation, by the death of all its members; 3. By surrender of its franchises

CORPORATIONS, MUNICIPAL

into the hand of the king; 4. By forfeiture of its charter through negligence or abuse of the franchise.

Corporations, Municipal. These bodies, which have acted so important a part in the history of modern Europe, originated in the Italian and provincial towns subject to the Roman sway.

In England we have no record of the internal constitution of our towns prior to the Anglo-Saxon settlement, and during those times our information is extremely scanty and imperfect. The magistracy in English towns appears to have been elective; that in Danish, hereditary. In Domesday Book we find in every town (eighty-two in all, in those parts of the record which remain to us) a certain number of persons mentioned as *burgesses*; a number sometimes equalling, sometimes falling far short of the houses enumerated. Boroughs at this period were exempt from the immediate jurisdiction of the sheriffs of the counties in which they were situate: they possessed their own hundred courts, leets, and view of frankpledge; but they were liable for various duties to the king, who was usually lord of the leet, i.e. exercised jurisdiction in the borough; and to the lord of the soil also, if there were any. It became usual after the Conquest for the king to let the fees and revenues thus due, together with the right of appointing the officers of justice, to the burgesses in general; and by this species of enfranchisement the borough became an independent municipality. But a free borough was constituted by having, in addition to those powers, exemption from the king's tolls, granted to its burgesses by royal charter. Such continued to be, in substance, the condition of English boroughs for several centuries.

During all this period no one seems to have doubted the capability inherent in the burgesses of a town, as a community, to take and enjoy lands, tolls, or other hereditaments, to themselves and their successors. But about the period of the reigns of Henry V. and Henry VI., the increasing subtlety of our legal system, and more particularly the notions introduced by the study of the civil law, appear to have occasioned the custom of granting charters in a new form. It appears to have been thought that the power of holding lands in succession, and the right of suing and being sued by a common name, could not in strictness be enjoyed, except by a body constituted for those very purposes by the king's grant. Hence originated charters or letters of incorporation, granted to the men or burgesses of towns jointly with the mayor, bailiff, or other chief officer; and thus municipal corporations in the strict legal sense were first constituted.

But previously to this time it is probable that a great change had taken place, in most towns, in the character of the class of 'men' or 'burgesses' to whom these charters were granted. As the privileges of burgess-ship became more valuable, additional difficulties

CORPORATIONS, MUNICIPAL

were thrown by the governing body in the borough in the way of its acquisition. While the old household right remained in some places, it was lost in others. In its stead, or by its side, arose the rights of freemen of a guild or trade; those of the holders of particular tenements, which alone were recognised as conferring on their occupant the title of burgess; those of freeholders in cities, counties of themselves, &c. And hence the variety of the old parliamentary franchise [PARLIAMENT], as members of parliament were elected by the burgesses. Hence the corporations, which were constituted by the charters of Henry VI. and Edward IV., were already very different bodies from the general mass of dwellers in a town. But close corporations, properly so called, were not established until the reigns of the Tudors, when the first 'governing charters' were granted. [BOROUGH.] By these new charters the powers of municipal government were usually vested in a mayor and common council: the latter consisting of councillors and aldermen; the former of whom were selected in various ways, by the whole of the council or the aldermen; the aldermen mostly nominated by and out of the rest of the council. In these bodies the control over the town funds, the civil and criminal jurisdiction of the town, and police authority within its limits, became vested. The freemen, as well as the commonalty, thus ceased to be members of the governing body; but the former retained the extensive pecuniary advantages which in many places belonged to them.

The causes of this revolution, and of the gradual change by which the municipal bodies became more and more exclusive in their character, are chiefly to be found in the parliamentary franchise enjoyed by most of the corporate boroughs. When the House of Commons became an important body in the empire, the crown, as well as the noblemen and the powerful individuals to whose estates the boroughs were contiguous, had a strong and direct interest in controlling the nomination of members. This was much more easily effected by the agency of select bodies, such as the corporations, than by influencing the votes of an independent community. Hence, while in the larger places the corporation, usually devoted to the interest of its patron, exercised a decisive or a strong authority in controlling elections, in many smaller boroughs the elective franchise became in effect confined to the corporation itself, by means of the freemen who were closely associated with it. Thus the system of close corporations, established under the Tudors, acquired continually more strength and more exclusiveness. The governing bodies in the previous reign seem also to have assumed in many places the power, which has been since so liberally exercised, of admitting to the rights of freemen, or burgesses, whom they pleased, either by free gift or purchase. The great bulk of the property of corporations, both that enjoyed by them to their own use, and that of which they were trustees for charitable purposes,

seems to have been acquired after the first charters of incorporation were granted, and previously to the Revolution.

In the reign of Charles II., when the corporate bodies in the larger towns had become for the most part attached to the Whig interest, and hostile to the court, they were attacked by the crown through the famous writs of quo warranto. These were writs issued out of the King's Bench to the municipal bodies, to enquire by what right they exercised their jurisdictions and enjoyed their franchises; and the object was to contest the validity of the ancient charters, or at least to terrify them into surrendering them into the king's hands, and receiving new ones from him. Many such surrenders were actually made, and new charters granted: these, however, were recalled by a proclamation of James II., and the old ones regranted or revived; and this proclamation was allowed, after the Revolution, to have the force of law. A few boroughs, however, did not accept the restoration of their charters, and remained without a corporation. From the period of the Revolution little or no change of importance took place in the constitution of the towns or their governing bodies, until the passing of the Municipal Reform Act in 1835. By this Act (5 & 6 Wm. IV. c. 76) the municipal franchise is made uniform all over the kingdom. In order to enjoy it, an individual must have occupied a house, warehouse, counting house, or shop, within the borough, for three years; and must have been rated to all poor rates in respect of such premises during the whole of such time; and must be enrolled on the burgess list, which is framed by the overseers of the parishes and revised every year by the mayor and assessors. He must also have resided within seven miles of the borough during that time. There are also provisions for the cases of successive occupancy and change of residence. These burgesses form the electoral body. They choose—1. The councillors; of whom the number is limited by the Act, according to the number of wards of which each borough consists (this number being also specified by enactment, and varying from one to sixteen). No person can be qualified as a councillor, or alderman, unless he is a burgess possessing a certain amount of property (1,000*l.*) or a rating at 30*l.* per annum, in boroughs having four wards and upwards; 500*l.*, or 16*l.* per annum, in boroughs not having that number. One third part of the councillors go annually out of office. 2. The council, i. e. the mayor, existing aldermen, and councillors, jointly elect every year the aldermen from among the qualified burgesses; half of whom go out of office every third year. 3. The councillors and aldermen together elect out of their own united body the mayor, whose office is annual. The mayor, aldermen, and councillors together form the council. The town-clerk, treasurer, &c. are appointed by the council during pleasure.

With regard to existing rights, freemen are

CORPS D'ARMÉE

retained, so as to enjoy their rights of property and parliamentary franchise; but they can no longer be made by gift or purchase; and they must be inhabitants of the borough. The income arising out of the corporation property is to form a borough fund; which is to be applied, subject to existing claims, to the payment of salaries and other municipal expenses, prosecutions, maintenance of the gaol, &c. &c.; and if the fund be insufficient for these purposes, the council can impose a rate to supply the deficiency.

With respect to jurisdiction, the council of every borough now having a separate court of quarter sessions, or desiring to attain one, may apply to the king to retain or to acquire it; on which the king may, if he pleases, appoint a recorder to be paid by the town, being a barrister of five years' standing. This officer is to hold the court of quarter sessions of the peace, in which he is to be sole judge. Borough courts of record are to be retained as heretofore, and those in which a barrister of five years' standing acts as judge have power to try personal actions to the amount of 20*l*. The history of municipal corporations has been often written, and generally with much party spirit and unfairness. Those who wish to study it in the only authentic records, viz. charters and other documents, will find the most abundant collection of them, chronologically arranged, in *Messrs. Merewether and Stephen's History of Boroughs*, 1836.

Corps d'Armée. An army in the field is divided into *corps*, each consisting of two or more divisions, which are subdivided into brigades, and these again into battalions or regiments.

Corps Législatif (Fr.). The Lower House of the present French legislature, under the imperial government; constituted by senatus-consulte of 1867. The deputies are elected by universal suffrage for six years, in the proportion of one to 35,000 electors. It discusses and votes on projects of law and taxation, presented by government. These projects are submitted to *commissions*, i.e. committees. But any amendment which the commission may propose is referred to the government (*Conseil d'État*), and without its approval cannot be submitted to the legislative body. A project finally adopted is next submitted to the *SENAT* [which see]. The session of the legislative body lasts three months: its sittings are public; but the public may be excluded on the demand of five members.

Corpus Callosum (Lat. *hard body*). In Anatomy, the great commissure, or band of transverse fibres, connecting the hemispheres of the cerebrum.

Corpus Christi (Lat. *body of Christ*). A festival of the Romish church, instituted by Urban IV. A.D. 1264, and celebrated on the first Thursday after Trinity Sunday, in honour of the Eucharist.

Corpus Juris (Lat. *body of law*). *Corpus Juris Romani*, the collection of the authentic

CORPUSCULAR PHILOSOPHY

works containing the Roman law as compiled under Justinian. The *Corpus Juris* comprehends the *Pandects*, the *Institutes*, the *Code*, and the *Novels of Authentica*, i.e. the latter constitutions of Justinian; to which, in some editions, are added a few issued by his successors. M. Beck has lately published at Leipzig the most complete edition. There are likewise publications styled *Corpus Juris Canonici*, *Germanici*, *Feudalis*, &c.

Corpus Luteum (Lat. *yellow body*). In Anatomy, a yellowish mass which is formed in a Graafian vesicle subsequent to the escape of an ovum. It is largest, most conspicuous, and lasting after the escape of an impregnated ovum in the human subject.

Corpuscula Vermiformia (Lat. *worm-shaped bodies*). In Vegetable Anatomy, are synonymous with strangulated or necklace-shaped ducts, a kind of spiral vessel found chiefly in the knots and contracted parts of stems.

Corpuscular Action. The power or influence which the minute particles, or atoms, or *corpuscles* of matter, exercise on each other, and which is the cause of all chemical changes.

Corpuscular Mechanism. That branch of mechanical science which is concerned with the phenomena of cohesion. These phenomena indicate some relation between the centres of the particles cohering. The exact nature and cause of this relation is not known; but if it could be ascertained as clearly as the law of gravitation, we should at once be able to determine precisely the result of any position which we may give to the particles of bodies. Meanwhile, we have to content ourselves with a careful observation of all secondary laws of action.

Corpuscular Philosophy. A system of physics, known also as the Atomic Philosophy, in which all the phenomena of the material world are explained by the arrangement and physical properties of the corpuscles or minute atoms of matter. A doctrine of this sort was anciently taught in Greece by Leucippus and Democritus, from whom Epicurus borrowed the idea of monads or atoms, which he regarded as the ultimate principles of all things. These monads in the Epicurean theory had the properties simply of hardness and gravity; and hence the gases, which have assumed so much importance in modern chemistry, were not taken into account. This theory forms the subject of the magnificent poem of Lucretius, *De Rerum Natura*, which endeavours to make the Epicurean philosophy a guide of life. But the didactic vehemence of the poet failed to win a permanent reputation whether for his ethical or his physical philosophy. The latter was manifestly at variance with facts, and thus it came at last to be regarded as a wild dream. But the idea has been revived under a different form in the modern atomic theory, which asserts that matter may be resolved by division into certain ultimate elements, which again enter synthetically, in definite proportions, into the constitution of all things.

CORRECTING

Correcting. In Printing, in the first instance, is the mode of amending and putting right the errors in the types made by the compositor; in the next, it is the correcting of the proof sheets of a work by the author or editor. The following explanation of the marks in general use, with the annexed specimen, will show the mode of correcting proofs in a way which will be clearly understood by the printer.

1. Where a word is to be changed from small letters to capitals, draw three lines under it, and write *cap.* in the margin.
 2. Where there is a wrong letter, draw the pen through it, and write the correct one in the margin.
 3. A letter turned upside down.
 4. The substitution of a comma for another point, or for a letter put in by mistake.
 5. The insertion of a hyphen.
 6. To draw letters close together.
 7. To take away a superfluous letter or word, the pen is struck through it, and a round top *d* made opposite, being the contraction of *delete*, to expunge.
 8. Where a word is to be changed to Italic, draw a line under it, and write *Ital.* in the margin; and where a word is to be changed from Italic to Roman, write *Rom.*
 9. When words are to be transposed, these ways of marking them are shown; but they are not usually numbered unless more than three are changed.
 10. The transposition of letters in a word.
 11. To change one word for another.
 12. The substitution of a period or a colon for any other point. It is customary to encircle these points.
 13. The substitution of a capital for a small letter.
 14. The insertion of a word or letter.
 15. When a paragraph commences where it is not intended, connect the matter by a line, and write in the margin opposite *run on*.
 16. Where a space or a quadrat stands up and appears, draw a line under it and make a strong perpendicular line in the margin.
 17. When a letter of a wrong size or of a different face is used, draw a line either through it or under it, and write opposite *w.*, for *wrong font*.
 18. The marks for a paragraph, when its commencement has been omitted.
 19. When a word has been struck out, and it is subsequently decided that it shall remain, make dots under it, and write the word *set* in the margin.
 20. The mark for a space where it has been omitted between two words.
 21. To change a word from small letters to small capitals, make two lines under the word, and write *sm. caps.* opposite. To change a word from small capitals to small letters, make one line under the word, and write in the margin *lc.* or *lower case*.
 22. The mark for the apostrophe; and also the marks for turned commas, which designate extracts.
 23. The manner of marking an omission, or an insertion, when it is too long to be written in the side margin. When this occurs, it may be written either at the top or the bottom of the page.
 24. Marks when lines or words are not straight.
- The subjoined specimen when corrected would read as follows:—
- ANTIQUITY, like every other quality that attracts the notice of mankind, has undoubtedly votaries that reverence it, not from reason, but from prejudice. Some seem to admire indiscriminately whatever has been long preserved, without considering that time has sometimes co-operated with chance: all perhaps are more willing to honour past than present excellence; and the mind contemplates genius through the shades of age, as the eye surveys the sun through artificial opacity. The great contention of criticism is to find the faults of the moderns, and the beauties of the ancients. While an author is yet living, we estimate his powers by his worst performances; and when he is dead, we rate him by his best.
- To works, however, of which the excellence is not absolute and definite, but gradual and comparative; to works, not raised upon principles demonstrative and scientific, but appealing wholly to observation and experience, no other test can be applied than length of duration and continuance of esteem.

Antiquity, like every other quality that attracts the notice of mankind, has undoubtedly votaries that reverence it, not from reason/ but from prejudice. some seem to admire indiscriminately whatever has been long preserved, without considering that time has sometimes co-operated with chance: all perhaps are more willing to honour present than past excellence; and the the mind contemplates genius through the shades of age, as the eye views the sun through artificial opacity/ the great contention of criticism is to find the faults of the moderns, the beauties of the ancients.)

(While an author is yet living, we estimate his powers by his worst performances; and when he is dead, To works, however, of which the excellence is not gradual but absolute and definite and comparative; to works, raised not upon principles demonstrative and scientific, but appealing wholly to observation and experience, no other test can be applied than length of duration and continuance of esteem.)

we rate them by his best.

CORRECTION

Correction (Lat. *correctio*). In the Fine Arts. With the Italians the word, *corrasione*, is used to denote an exact acquaintance with the different proportions of the parts of a body or design generally; but with us the term is applied to those emendations of inaccuracies or alterations of first thoughts, which they call *pentimenti*, to be seen under the surface of the finished picture, and which are accounted indications of its originality; a *pentimento* being a repentance or second thought.

Corridor. In Architecture, a gallery or open communication to the different apartments of a house.

Corrosive Sublimate. One of the chlorides of mercury, composed of 100 mercury + 86 chlorine. It is an acrid poison of great virulence: the stomach-pump and emetics are the surest preventives of its deleterious effects when accidentally swallowed; white of egg has also been found serviceable in allaying its poisonous influence upon the stomach. Its specific gravity is 62. It requires 20 parts of cold water, but only 2 of boiling water, for its solution. Corrosive sublimate has been called *bichloride*, *perchloride*, and *oxymuriate* of mercury; it is now commonly regarded as a compound of 1 atom or equivalent of mercury = 100, and 1 of chlorine = 86: its equivalent, therefore, is 136. *Calomel*, which is the other chloride of mercury, is tasteless, insoluble in water, and comparatively mild in its operation; acting rather as a purgative than as a poison: it consists of 2 atoms of mercury and 1 of chlorine, and is therefore called a *subchloride* or *dichloride* of mercury. [MERCURY; CALOMEL.]

Corrugate (Lat. *corrugatus*, from *ruga*, a wrinkle). In Zoology, the surface of an animal is so called when it rises and falls in parallel angles more or less acute.

Corrugated Iron. Sheet iron that has been rolled into a series of waves is known under this name; and in this form it is frequently used for temporary roofing, or for covering spaces in a definite manner. The waves are made in England from $5\frac{1}{2}$ to 6 inches from centre to centre; in France they are, however, much increased, and are made to extend even to 13 inches. They are either impressed by the roller, or they are produced by hydrostatic pressure upon a movable upper block driven upon a lower one; but whatever system be adopted for the production of the waves, it is evident that none but the best iron will resist this action. There are at present no observations upon record to allow us to form an opinion on the strength given by the process of rolling, so that the practice of engineers in this matter is purely empirical. Railway bridges of from 10 to 16 feet span have been executed in this material; a roof of less than 25 feet span may be executed without a tie rod; beyond that span, however, it is necessary to guard against the lateral thrust and the bending of the tie rod in its own length. Corrugated iron is largely used for the panelling of houses sent out to the colonies;

CORUNDUM

for which purpose its immunity from the attacks of the white ants, and its freedom from shrinking, give it a very decided advantage; but the conducting power of the metal renders it necessary to introduce some other substance between it and the weather. This inconvenience also applies to roof-coverings.

Corsair (Ital. *corsaro*). A term used in the south of Europe and some other parts for a pirate or his ship. The corsairs of Barbary were commissioned by their princes to attack the merchant ships of hostile countries.

Cortes (Span.). The old assembly of the estates in Leon, Castile, Arragon, and Portugal. These estates were framed, as elsewhere, of nobility, dignified clergy, and representatives of the towns. In Arragon they were presided over by a high officer, termed *justicia*, with powers in some respects sufficient to control the monarch. The origin of popular representation, in the cortes of the several kingdoms out of which that of Spain was finally formed, is assigned to a date as early as the twelfth century; but the deputies sent by the towns were irregularly summoned, frequently did not attend, and the numbers which appeared for each town frequently bore no proportion to the relative size of the different places. In the fourteenth century the power of the cortes seems to have been at its height, after which it gradually decayed, and under the government of Ferdinand and Isabella was reduced almost to a nullity. After the time of Philip II. the cortes of Spain were only occasionally convoked on the accession of kings, and their sittings were a mere form. In 1811, during the French invasion, they were convoked at Cadix, and conducted the affairs of that kingdom during the war of independence. In 1814, Ferdinand VII. dissolved them, and declared all their decrees null. In 1820, the cortes met again, and adopted a new constitution; in 1821, the people of Portugal followed the same example: both constitutions were overthrown in 1823; the first by the French invasion, the latter by a counter revolution. The later events of Spanish and Portuguese history have again called these national assemblies into existence.

Corticifers, Corticeiferi (Lat. *cortex*, bark, and *fero*, I carry). Those Polyps whose uniting fleshy substance is spread, like the bark of a tree, over a central calcareous or corneous axis.

Cortile. In Architecture, an open quadrangular or covered area in a dwelling-house, surrounded by the buildings or offices of the house itself. It means also a courtyard.

Cortina (Lat.). A term used in describing Fungi, to denote that portion of the velum which adheres to the margin of the pileus in fragments.

Corundum. A crystallised or massive mineral, composed of nearly pure anhydrous alumina. It is the hardest of all known substances, except the diamond, on which account it is much used for polishing steel and cutting gems. The term *Corundum* or *Common Corundum* is

generally confined to the opaque rough crystals and cleavable masses, generally of dingy colours and often dark, while the term *Emery* embraces the more or less impure, massive, granular and compact kinds, and *Precious Corundum* the transparent brightly tinted varieties which are used as gems; the blue variety under the name of *Sapphire*, the red of *Ruby*, the yellow of *Oriental Topaz*, and the violet of *Oriental Amethyst*. The crystals which show a bright opalescent six-sided star in the direction of the vertical axis, are called *Asteria* or *Star-stone*.

Hexagonal crystals of Corundum are found in Cumberland and in Wicklow. The principal supplies are obtained from China, Ava, the East Indies, and Asia Minor.

Corvée (Fr.). In Feudal Law, the obligation of the inhabitants of a district to do certain services, as the repair of roads, &c., for the sovereign or the feudal lord. Some species of *corvée* were performed gratis; others for a fixed pay, but generally below the value of the labour performed.

Corvette (Fr.). One of the smaller vessels of war, and ordinarily the command of a commander. It has flush decks, three masts, and one tier of guns—on the upper deck. The masts are square rigged. A corvette rarely carries more than 26 guns. The Navy at present (1865) comprises 26 steam corvettes and two without steam.

Corvus (Lat.). A Linnæan genus of birds, now the type of a family (*Corvidæ*), belonging to the Conirostral division of the *Passeres* of Cuvier; and including, with the Crows proper, the Rollers (*Coraciæ*) and Birds of Paradise (*Paradisææ*).

Corvus. In Astronomy, one of Ptolemy's constellations, in the southern hemisphere.

Corybantes (Gr. *Κορυβαντες*). In Grecian Mythology, certain fabulous beings, said by some to be the children of Apollo and Rhytia. They may be compared with the Curetes, Cabeiri, and Itean Dactyls. (Thirlwall's *History of Greece*, vol. i. ch. iii.) The name (of which the origin is doubtful) was applied to the frantic priests of Rhea or Cybele, whose extravagances were taken as types of madness or frenzy in general.

Corymbum (Lat.). In ancient Architecture, an apartment in the gymnasium, attached to the Roman *BALNEÆ* [which see]. The name is derived from the Greek *κόρυμβος*, a *leathern wallet or sack*, filled with bran and olive-kittak, and which, when suspended at a certain height in the room, was swung backwards and forwards by the players.

Corylaceæ (Corylus, one of the genera). A natural order of arborescent or shrubby Exogenous plants, formerly called *Cupulifera*, inhabiting all temperate and some hot climates. They are distinguished from all European trees by theiramentaceous flowers and peculiarly veined leaves; and from other plants by their noctalous superior rudimentary calyx: by their fruit enclosed in a husk or cup; and by their

nuts, which contain but one cell and one or two seeds, in consequence of the abortion of the remainder. These plants are akin to *Betulaceæ* and *Salicaceæ*, from which they are distinguished by the presence of a calyx and the veining of the leaves. They are nearly allied to *Urticaceæ*, but differ from them in their many-celled ovary, pendulous ovules, and superior calyx. This order comprehends the Oak, Beech, Chestnut, and Hornbeam—well-known valuable forest trees; and the Hazel (*Corylus*), from which it takes its name.

Corymb (Gr. *κόρυμβος*). In Botany, a form of inflorescence consisting of a central axis, developing lateral pedicels, of which the lower are so long that their flowers are elevated to the same level as that of the uppermost.

Corymbiferae (Lat. corymbus, and fero, *I bear*). One of the divisions of the great group of *Compositæ* admitted by Jussieu. It comprehends those plants which, like the *Chrysanthemum* and the *Achillea*, have the flower-heads furnished with a ray; as well as those which, like *Artemisia*, although destitute of a ray, are similar to such plants in the greater number of their characteristics.

Corymbus (Lat.; Gr. *κόρυμβος*). In ancient Sculpture, the cluster of ivy leaves, berries, garlands, &c. with which vases were encircled. It was applied also to that mode of dressing the hair among the Greeks, by which it was tied in a knot or cluster on the top of the head.

Corypha (Gr. *κορυφή*, *summit*). A genus of tropical Fan-leaved Palms, one of which, the Talipot palm, *C. umbraculifera*, found in Ceylon and Malabar, grows to the height of sixty or seventy feet. Fans made of the leaves are carried before people of rank by the Cingalese. The leaves are also used as umbrellas, and for tents; and by the natives as a substitute for paper.

Coryphæna (Gr. *κόρυς*, a *helmet*, and *φαίνα*, *I show*). A genus of spiny-finned fishes, so called from the head being crested like a helmet. It belongs to the Mackerel family (*Scomberoides*); and includes the true dolphin, or changeable coryphæne (*Coryphæna hippuris*). The genus is now raised to the rank of a family, including, with *Coryphæna* proper, the subgenera *Centrolopus* and *Leptopodes*.

Coryphæus (Gr. *κορυφαῖος*). The leader of the chorus in ancient dramas; by whom the dialogue between the chorus and the other actors of the drama was carried on, and who led in the choric song.

Coryphodon (Gr. *κορυφή*, and *δούς*, *tooth*). A genus of fossil Perissodactyle mammalia, allied to *Lophiodon* and *Tapirus*. It has been found in the Eocene strata of England and France.

Coryza (Gr. *κόρυφα*). A copious running from the nose.

Cosecant of an Angle. The secant of the complement of that angle.

Cosine of an Angle. The sine of the complement of that angle.

COSMETICS

Cosmetics (Gr. *κοσμητικὸς*). Remedies to remove freckles and pimples from the face, and to improve the complexion.

Cosmical (Gr. *κοσμικός*). This word occurs frequently in the ancient astronomy, in which it is used to denote a particular position of a planet or star, at its rising or setting, in respect of the sun. A star is said to rise *cosmically* when it rises at the same instant that the sun rises; and to set *cosmically*, when it sets with the sun. *Cosmical* is opposed to *acronycal*, which signifies that a star rises at the instant the sun sets, and vice versa. The cosmical and acronycal risings of a star are invisible to the naked eye, because the light of the sun in the horizon effaces that of the star.

Cosmogony (Gr. *κοσμογονία*). The science which treats of the origin of the universe. If we except the cosmogony of the Indians, the earliest extant is that of Hesiod, which is delivered in hexameter verse. The first prose cosmogonies were those of the early Ionic philosophers, of whom Thales, Anaximenes, Anaximander, and Anaxagoras are the most celebrated. In modern times, a *Theory of the World* has been produced by Burnet. We do not include in this list of cosmogonies the researches of modern geologists, or the systems to which they have led. They may be said to hold the same place in relation to the old cosmogonies, which the astronomer or the chemist occupies in reference to the astrologers and alchemists of ancient times.

The different theories which have been formed to account for the origin of the world may be comprehended under three classes: 1st. Those which suppose the world to have existed from eternity under its actual form. Aristotle embraced this doctrine; and conceiving the existing universe to be the eternal effect of an eternal cause, maintained that not only the heavens and the earth, but all animate and inanimate beings are without beginning. 2nd. Those which consider the matter of the universe eternal, but not its form. This was the philosophical system of Leucippus, Democritus, Epicurus, and indeed most of the ancient philosophers and poets, who imagined the world either to be produced by the fortuitous concurrence of atoms existing from all eternity, or to have sprung out of the chaotic form which preceded its present state. 3rd. Those which ascribe both matter and its form to the direct agency of a spiritual cause.

Cosmography (Gr. *κοσμογραφία*). The science which treats of the construction, figure, and arrangement of all the parts of the world; and therefore comprehends astronomy, geography, and geology.

Cosmology. [*ΚΟΣΜΟΛΟΓΙΑ*.]

Cosmopolite (Gr. *κοσμοπολίτης*). A citizen of the world: one who makes the world his country.

Cosmorama (Gr. *κόσμος*, and *όραμα*, *I see*). A species of picturesque exhibition, consisting of a number of drawings, generally about eight or ten, which are laid horizontally round a

COSTATE

semicircular table, and reflected by mirrors placed opposite to them diagonally. The spectator views them through a convex lens placed immediately in front of each mirror. The pictures are illuminated by lamp-light; but the lamps are so placed that they cannot be reflected by the mirrors, and are therefore invisible to the spectator.

Coss. When algebra was first introduced into England, it was called the *Rule of Coss*; probably from the Italian *Regola di Cosa*, the *Rule of the Thing*; the unknown quantity being termed *cosa*, the thing. Hence *Cossic Art*, *Cossic Numbers*, &c., found in some old authors.

Cossacks. A people inhabiting those parts of the Russian empire which border on the northern dominions of Turkey, Poland, and the southern confines of Siberia. Both the name and origin of this people are involved in great uncertainty. They seem to have nothing Russian in their origin and character, and are probably a mixed Caucasian and Tartar race. They form a sort of independent republic, paying no taxes to Russia, but cheerfully contributing their numerous and valuable contingent of troops; and are well known as the most harassing light troops that ever exercised a predatory warfare in the train of any army.

Their dress is a short vest in the Polish style, large trousers of a deep blue colour, and a black sheepskin cap. Their arms consist of a sabre, long spear, musket, a pair of pistols, and a long whip, which they apply to their enemy as well as their charger's back. They are mostly members of the Russian Greek Church, and are described as a hospitable, generous, and disinterested people. Their numbers have not been estimated for nearly a century, when they amounted to 955,228 males.

Cost-book. In Mining usage, a book in which the names and shares of all the adventurers in a mine are entered, the legal transfer of shares being effected by a simple entry in the book.

Costa (Lat. *a rib*). In Botany, a term formerly confined to that bundle of vessels which passes directly from the base to the apex of a leaf; but which is better extended to all the main veins which proceed directly from the base to the apex, or to the points of the lobes.

Costal (Lat. *costa*). Belonging to the ribs.

Costardmonger (from *costard*, a large apple). An itinerant dealer in apples. The word is often written *costermonger*, and applied to hawkers and pedlars who sell fruit.

Costate (Lat. *costatus*, *ribbed*). In Botany, a term applied in two ways, in describing the venation of leaves: either to indicate the presence of but one rib, as in most leaves; or in speaking of cases where three or more ribs proceed from the base to the apex of a leaf, and are connected by cross veins. The latter are frequently called *nerves*, or *nervures*. If a leaf has its ribs all distinct from the very base, it is called *tricostrate*, *quinquecostate*, and so on; but if the ribs are united at the base in a

COSTATE

distinct manner, the term becomes *triplicostate*, *quintuplicostate*, &c.

COSTATA. In Zoology, the surface of the whole or part of an animal is so termed when it has several broad elevated lines.

Costs (Fr. *couter*; to *cost*, from Lat. *constare*: Wedgwood). In Law, the expenses to which parties are put in the prosecution and defending of actions. Costs are to be considered either as between attorney and client, i.e. the expenses and fees which the attorney is entitled to recover from his client; or as between party and party, i.e. that portion of the expenses to which a successful party has been put in his suit, which he is entitled in certain cases to recover from the unsuccessful one. Costs in the latter sense are not given by the common law. The statute of Gloucester (6 Edw. I. c. 1, s. 2) first enacted that the demandant should recover from the tenant the cost of his writ, if successful; and that this provision should extend to all cases where a man recovers damages. By a liberal construction of this statute, the costs of the writ are understood as the costs of the action, and its benefit is extended to plaintiffs in most cases where they would have been entitled to damages before that statute. Where, out of several issues, some are found for the plaintiff and others for the defendant, the plaintiff is now entitled to costs only on those issues on which he may succeed, and the costs of the defendant's issues will be deducted from his. The defendant's right to costs rests also on several statutes, principally 23 Hen. VIII. c. 16. Pauper suitors, i.e. such as will swear themselves not worth *5l.* in the world except their wearing apparel, and the matter in question in the cause, are excused from paying costs. And, subject to certain exceptions, any plaintiff who resorts to one of the superior courts in a case which would have been cognisable in a county court, and recovers no more than 20*l.* in an action arising on a contract, or no more than *5l.* for a wrong independent of contract, will have no costs, unless he satisfies the court or a judge that he had sufficient reason for taking that course. By 23 & 24 Vict. c. 126, s. 34, the plaintiff in any action in a superior court for an alleged wrong, who recovers less than *5l.* will have no costs, if the judge certifies that the action was not really brought to try a right, and that the trespass or grievance sued for was not wilful and malicious, and that the action was not fit to be brought. (8 Steph. Black. p. 673.) Double and treble costs were formerly given by statute in some cases, but this is now abolished. Costs are *taxed* as between party and party by officers of the court, and recoverable by execution or otherwise. As between attorney and client, the attorney has a right of action for costs; but his bill is liable to taxation by officers of the court. Costs in equity are more within the discretion of the court, than costs at law, but are usually awarded according to fixed rules.

Costume (Fr.). In Painting and Sculpture,

COTISE

this word has become used chiefly as a term denoting the particular sort of dress suitable to the subject, according to the time in which the action is supposed to have taken place; but the word has a more general signification, inasmuch as it includes the keeping of all the accessories, ornaments, utensils, &c. of such forms and colours as historical knowledge proves them really to have possessed.

In modern times painters have paid more attention to propriety of costume, as considerable knowledge on the subject has now been acquired, and egregious ignorance on the part of the painter is inexcusable; formerly, from a want of knowledge, accuracy was difficult, and the grossest improprieties were common. (Hope, *Costume of the Ancients*, 1812; Lacroix and Seré, *Le Moyen Âge et la Renaissance* &c. 1848-51; Meyrick's *Critical Enquiry into Ancient Armour* &c. 1842; Planché's *British Costume*, 1846; Shaw's *Dresses and Decorations of the Middle Ages*, 1843; and Strutt's *Dress and Habits of the People of England* &c. 1842.

Costus (Arab. *gosth*). A genus of *Zingiberaceae*, the roots of some of which are used as preserves. The *Costus* of the ancients, however, was the root of a composite plant formerly called *Aucklandia Costus*, now known as *Aplotaxis Lappa*.

Cotangent of an Angle. The tangent of the complement of that angle.

Cotarnine. A basic substance derived from narcotine by oxidising agents.

Côté Droit, Côté Gauche. [DEPUTIES.]

Coterie. A French word, supposed to be derived from the Lat. quot, *how many*, signifying literally a society or company. In the thirteenth or fourteenth century, when merchants were about to embark in any enterprise, they formed a coterie or company, each contributing his *quota* of goods or money, and deriving his *quota* of profit. But the term soon acquired a more extended signification, being applied to any exclusive society in which interesting subjects (chiefly literary and political) are discussed, each member being supposed to contribute his *quota* or share of information.

Cotham Marble. A variety of Lias Limestone of a pale grey colour, which when cut at right angles to the bedding displays dendritic markings bearing a fanciful resemblance to landscapes and ruins; for which reason it has, also, received the names of *Ruin* or *Landscape Marble*. It is found in the Rhetic (or Penarth beds) of Cotham and other places, near Bristol.

Cothurnus (Lat.; Gr. *κόθουρος*). In classical Antiquities, the high buskin worn by tragic actors to increase their apparent height: thence used, metaphorically, by ancient writers to signify the tragic art.

Cotise (Fr. *côté, side*). In Heraldry, a diminutive of the bend, being one-half the width of the bendlet: generally borne in couples, with a bend or charges between them. A bend, *fees*, &c. between two cotises, is termed *coticed*.

COTTABUS

Cottabus (*ατράβος*). A celebrated Greek game. It consisted in throwing wine from cups into little basins of metal suspended in a particular manner, or floating in a large vessel of water; so that dexterity might be shown in throwing it without spilling, in producing a particular sound, &c.

Cottage Allotments. Portions of ground allotted to the dwellings of country labourers for the purpose of being cultivated by them as gardens. Sometimes these allotments are placed adjoining the dwellings, in which case they are more commonly called *cottage gardens*; but at other times they are placed at a distance from the cottage, and form small portions of a large enclosure; and to this kind of cottage garden the term *allotment* is more properly applied than to the other. The object in both cases is to enable the cottager, by growing vegetables and roots of various kinds, not only to supply his own family, but to keep pigs, rabbits, poultry, &c. Such being the uses of cottage allotments, the advantage of each cottage having its garden surrounding it, instead of at a distance, is sufficiently obvious. In the latter case, the cottager must necessarily lose much time in travelling backwards and forwards from his house to his garden; and his wife and children will often be prevented from employing themselves in it. In such a garden he cannot grow fruits, because they would be comparatively unprotected; nor can it be worth his while to grow flowers in a place where they would not prove an ornament to his dwelling. On the supposition that the cottager has his pigsty close to his dwelling, the food for the pigs must be brought home from the allotment; and the manure made by them must be carried out again. It is well known to all persons of any experience on this subject, that by far the most valuable part of the manure made by the cottager, such as house-waste, &c., may be included under the term *liquid manure*; and this, when the allotment is at a distance, may be considered as entirely lost, the cottager being without either convenience or time for carrying it out. In point of usefulness, therefore, a cottage allotment in a field, at the distance of a furlong or less from the cottage, is not worth half what it would be if adjoining the dwelling; while in point of enjoyment to the cottager, and of ornament to the roadside, it is hardly worth anything. On the other hand, the labourer who has a lease of a comfortable cottage surrounded by a garden, even if the latter should not be larger than the eighth part of an acre, may grow good and wholesome vegetables and fruits; he may have his live stock of pigs, poultry, rabbits, and bees; he may ornament his house front and the borders of his walk with shrubs and flowers; and he has the wages of his labour for the purchase of those comforts and luxuries which his garden does not afford. The time, it is to be hoped, is not far distant when the humblest country labourer will possess such a cottage and garden; but it is necessary that the country labourer should acquire pre-

COTTON

viously a taste for these comforts by seeing them possessed by others of his class; and for this we must look partly to the country labourers themselves, partly to the government for the establishment of a system of universal education which shall raise the taste of the humblest part of society, and partly to the humanity and sympathetic feeling of the landed proprietors; because it is to them we must look, in the first instance, for building the cottage and accompanying it with garden ground.

Cottier System. This term has been applied to that tenure of land in which the labourer rents portions of the soil from the owner, and in which the price of the occupancy is determined by competition and not by custom. It was characteristic of Ireland before the famine, and is not yet wholly extinct. An analogous kind of tenancy exists in India, though it does not appear that the exceptional evils of the Irish practice have ever been represented in the Eastern peninsula.

As the tenancy was annual, the privilege of occupancy was put up to auction, and the pressure of population caused a vehement competition, the peasants offering many times over the value of the rent. Of course such a rent could not be paid, but all that could be extracted from the tenant was got, and hence his condition reached no higher than the barest subsistence on the cheapest food.

In the great majority of cases where the labourer is also the cultivator of the soil for his own profit or subsistence, his interest in the land is at least permanent, i.e. he is either a proprietor, as in Flanders, Belgium, France, and other countries, or he enters into a perpetual lease with the lord of the soil, as is the case with the metayer tenant.

When a capitalist engages to rent land, he is but partially affected by competition. In other words, he would not choose to hold at rent except he had reason to believe that he would procure the ordinary rate of profit on his outlay. But when the person who bids is exposed to the full effect of a demand for what is a necessary of life, the optional employment of his labour and such capital as he may possess is taken away; he must either outbid his neighbours or starve. This was the case with the cottier biddings. Hence it has been stated that a cottier has been known to bid at an auction 450*l.* a year for a farm not worth 50*l.* (*Lord Devon's Commission*, quoted by Mr. Mill, vol. i. p. 391, edit. 1862.)

Cotton (Span. algodón, Arab. go'ton, algodon: Wedgwood). A species of vegetable wool, which envelops the seeds of various species of *Gossypium*, especially of *G. herbaceum*, of which there are many varieties. The kinds of cotton met with in the market are usually designated by the names of the places from which they are brought; but practically, they are all divided into the two great classes of *long-stapled* and *short-stapled*. Its goodness depends on its colour, and the length, strength, and fineness

COTTON

of its fibre. The general chemical characters of cotton are those of *lignin*. It is peculiarly susceptible of combination with certain metallic oxides or bases; whence the facility with which it is locally dyed, as in the process of *calico printing*.

Corrosion. A term of Engineering which expresses the small pieces of iron driven to retain the keys or wedges in their position.

Cotton Manufacture. In modern times cotton has attained to an importance among vegetables second only to that of corn, if we regard the number of persons engaged in its culture and in its manufacture. The manufacture of cotton wool into articles of use and ornament appears, indeed, to have been carried on in India from the remotest antiquity; but it has not made any very great progress in the East, and obtained no footing worth mentioning in Europe till the last century.

The truth is, that this industry, though it now affords employment and subsistence to many hundreds of thousands of persons in this and other countries, is almost wholly a consequence of discoveries and inventions made in Great Britain and the United States, since the middle of last century. Previously to that period the manufacture was everywhere confined within the narrowest limits. Owing to the difficulty of separating the wool from the seed, its price, so long as this operation had to be performed by the hand, was naturally high; while the cost of its spinning and weaving by the wheels and looms in use previously to 1760 added so much to the price of cloth, that cotton articles were suited only to the use and demand of the better classes of society; and it seems unreasonable to suppose that the manufacture could have been materially extended without a greatly increased facility of production. But in this respect the most signal and extraordinary improvements have been made. The *Jenny* invented by Hargreaves in 1767 enabled one person to spin 80 or 120 threads with about the same facility that a single thread had been previously spun. The *jenny*, however, was fitted only to spin the softer descriptions of yarn, or that used as *weft*, being unable to give the thread the firmness and hardness required in the yarn used as *warp*. But this deficiency was soon supplied: the genius of Arkwright completed what Hargreaves had begun, by inventing the spinning frame—that wonderful piece of machinery which spins any number of threads of any degree of fineness and hardness, leaving to man merely to feed the machine with cotton, and to join the threads when they break! Nearly at the same time that the spinning department was thus wonderfully improved, Dr. Cartwright, a clergyman of Kent, invented the loom, which has

by the hand. Improvements were being made, Watt was perfecting the steam engine, and was thus not only supplying the manufacturers with a new power applicable to every purpose, and easy of com-

COTTON MANUFACTURE

trol, but with one that might be placed in the most convenient situations, and in the midst of a population trained to industrious habits.

Still something remained to complete this astonishing career of discovery. Without a vastly increased supply of the raw material at a lower price than it had previously brought, the inventions of Hargreaves, Arkwright, and Watt would have been of comparatively little value. Luckily, what they did for the manufacturers, Mr. Eli Whitney did for the cotton growers. He invented a machine by which cotton wool is separated from the seed with the utmost facility and expedition. Previously to 1790 the United States did not export a single pound weight of raw cotton. In 1792 they exported the trifling quantity of 133,328 lbs. Whitney's invention came into operation in 1793; and in 1794, 1,601,760 lbs., and in 1795, 5,276,306 lbs. were exported! And so astonishing has been the growth of cotton in the interval, that in 1849 the exports from the United States amounted to the prodigious quantity of 1,026,602,269 lbs.!

The chief source of cotton wool up to the year 1862 was the Southern States of the American Union, the supply from this region being abundant and the quality good. Since the civil war, however, commenced, this supply has been greatly reduced, the quantity imported in the year 1864 being little more than one-fifteenth of that sent in 1860. The gap has been partly filled by a great increase from the East Indies, Egypt, and Brazil; and within the last two years China has sent a considerable contribution. It is even said that cotton is being cultivated largely, and becoming an important branch of agriculture in several parts of Southern Europe.

A cotton mill is probably, all things considered, the most astonishing triumph of skill and ingenuity. All the various operations, from the carding of the wool to its conversion into a texture as fine almost as that of the gossamer, are performed by machinery. Each of the workmen at present employed in a cotton mill superintends as much work as could have been executed by 200 or 300 workmen sixty or seventy years ago, and yet, instead of being diminished, the numbers employed have increased even in a still greater proportion! It would be curious to investigate how many persons in the Old and New Worlds directly depend for subsistence on the inventions and discoveries of the founders and improvers of this great manufacture. They certainly amount to several millions, while there is scarcely anyone in any country, however remote or barbarous, who is not indebted to them for an increase of comfort and enjoyment.

The subjoined statement, taken from the circular of Messrs. George Holt and Co., cotton brokers at Liverpool, dated December 31, 1864, gives an account of the progress of the import of the raw material into Great Britain from 1820 to 1864 inclusive:—

COTTON MANUFACTURE

Statement of the Number of Bales of Cotton Wool consumed in the United Kingdom from 1820 to 1864, both inclusive, with the Average Weight of the Bale in each Year.

Year	Bales in Thousands	Average lbs. per Bale	Year	Bales in Thousands	Average lbs. per Bale
1820	467	258	1843	1,367	379
1821	499	258	1844	1,429	381
1822	545	267	1845	1,574	385
1823	560	275	1846	1,586	387
1824	605	273	1847	1,558	381
1825	600	278	1848	1,464	384
1826	611	294	1849	1,590	396
1827	675	297	1850	1,616	398
1828	732	297	1851	1,663	398
1829	745	294	1852	1,661	397
1830	832	298	1853	1,904	400
1831	856	306	1854	1,967	394
1832	891	311	1855	2,101	399
1833	880	326	1856	2,183	408
1834	919	330	1857	2,031	416
1835	954	333	1858	2,174	417
1836	1,012	343	1859	2,532	424
1837	1,057	346	1860	2,632	429
1838	1,207	346	1861	2,364	426
1839	1,114	343	1862	1,186	381
1840	1,261	367	1863	1,378	370
1841	1,192	367	1864	1,566	380
1842	1,160	375			

Manchester, or rather Lancashire, is the grand seat of the English cotton manufacture; and next to it Cheshire, Nottinghamshire, the West Riding of Yorkshire, and Cumberland are its principal seats. Glasgow with the surrounding district is the seat of the manufacture in Scotland. In Ireland it is principally confined to Belfast; but there it is of very limited dimensions, and is said to be rather on the decline.

The cotton manufacture has for the last three years (1862-64) suffered under very serious depression in consequence of the failure of supply from the southern portion of the United States. The circumstances which led to the civil war are so recent and so vast that there is no space to enter into them, even were a disquisition on these subjects relevant to the question before us.

The growth of the cotton manufacture was reciprocated by the extension of cotton planting in those states of the American Union in which slavery was instituted and protected. It was no doubt unfortunate that any large portion of British industry should be dependent on a single country for its supply of raw material, and particularly so when we consider the nature of the labour by which it was procured, and the manifest disagreement which prevailed between the two political sections of the Union on the question of slavery and its extension. When at last war broke out, it was confidently expected by those who sympathised with either side, that the struggle would be short, and end either in the submission or in the independence of the South. But these predictions have been falsified by events, and meanwhile the supply from these regions, except to a very unimportant extent, has been suspended. Nor does it seem likely, whatever be the result of the war, that the production

COTYLEDONS

of cotton in the semi-tropical parts of North America will ever recover its former proportions. In any event the settlement of the country must be a work of time, and in the interval other countries will occupy at least a portion of the trade, once almost a monopoly of the American planters.

The demand for cotton wool has called out prodigious activity in many parts of the world. Cotton has an exceedingly wide geographical range, and is naturally diffused over all the warmer countries of the globe. When once capital is employed in its systematic cultivation, and machinery is supplied for cleansing the seeds from the wool, there is little doubt that this staple will be largely grown, and that it will be imported from an increasingly wide area.

There is no reason to fear that the manufacture, seeing how nearly it affords an absolute necessary of life, will not revive and flourish as fully as before its partial but serious depression; and we may venture on predicting, that, great as has been the suffering induced by the temporary deprivation of the raw material, there is nothing which is more likely to civilise the world, and promote the best interests of many nations, than the general demand which has sprung up for this commodity, and the fullness with which a response has been given.

Cottus (Dor. Gr. *κόττα*, a head). A genus of spiny-finned fishes; so called on account of the large size of the head. It includes two British species, viz. the Father-lasher (*Cottus bubalis*) and the Sea Scorpion (*Cottus scorpio*); both of which are dreaded by fishermen on account of the painful and dangerous wounds which they inflict by means of the spines with which the gill-covers are armed.

Cotunnite. A native chloride of lead found in the crater and in some of the more recent lava of Vesuvius. Named after a medical man of Naples.

Cotyledon (Gr. *κοτυληδόνη*). In Botany, the seminal leaf of a plant. This organ forms a part of the embryo, and nourishes the plumule and radicle at their first period of development, before they are able to subsist upon the organisable matter absorbed by the latter from the earth. Exogenous plants have generally two cotyledons, Endogenous plants generally one only; but there are exceptions in both cases. The latter class of plants seldom elevate their cotyledon above ground, and never convert it into a green leaf-like body, but usually leave it behind them within the integuments of the seed; the former frequently raise their cotyledons above the soil in the form of small green leaves, as in the garden radish; but there are very numerous exceptions to this, as in the pea, the oak, the chestnut, &c.

Cotyledons. This term was applied by Aristotle to designate the sucking-cups of the arms of the Dibranchiate Cephalopoda. In Comparative Anatomy, the cup-shaped vascular productions of the chorion in Ruminants, serving the office of a placenta, are so called.

(Gr. *σπῆλαια, a cup*). In Botany, a term used in describing the general form of organs to denote a rotate figure with an erect limb.

Couch. A layer or heap of barley, moistened and prepared for malting; also the name of that part of the malting floor on which the barley is spread out.

Couch Grass. A kind of grass, botanically known as *Triticum repens*, with underground running rhizomes, forming a very troublesome weed in cultivated ground, whether garden or farm.

Couchant (Fr.). In Heraldry, a term applied to a beast when represented as lying on the ground.

Couching. In Agriculture, clearing land from Couch grass, which is effected by first pulverising it, and then, in very dry weather, collecting the couch by harrows, or by a horse rake, such as that used for collecting stubble, and which so applied is called a *couch rake*.

Couching. One of the operations to restore vision in cases of *cataract*: it consists in depressing the opaque lens, so as to remove it out of the axis of vision.

Cough. This term is applied to a spasmodic action of the respiratory organs, occasioning a sonorous expulsion of air from the lungs: it is very commonly symptomatic of other affections; and some nosologists have considered that it is always so, and never idiopathic. Many cases of cough depend upon the extension of *catarrh* to the trachea and bronchiae, which become loaded with mucus or phlegm, the efforts to expel which constitute coughing. Others are perhaps referable to a vitiated secretion; and others to imperfect action of the absorbents, by which the natural mucous secretion remains and accumulates in the air-vessels, and by evaporation becomes inspissated and irritating; this appears to be one of the causes of the dry cough to which old people are subject. The treatment of catarrhal cough consists in allaying irritation by demulcents, such as mucilaginous drinks and lozenges, which, acting upon the glottis, sympathetically affect the trachea and its ramifications: amongst these, extract of liquorice, and lozenges made of it and equal parts of gum tragacanth, are very effectual.

Stimulants and full diet are to be avoided, and inflammatory symptoms carefully guarded against; for these are often brought on by the violence of the cough. It is not unfrequently necessary to call in the aid of sedatives, expectorants, and perients. Amongst the former, small doses of Dover's powder (opium and ipecacuan), or of equal parts of it and extract of henbane, are very serviceable; and it is not uncommon to observe a troublesome cough disappear after a brisk dose of physic. An emetic will also sometimes effect its cure; so that coughs have been by some considered as symptomatic of a vitiated state of stomach and bowels. Where a cough periodically returns at night, and is not inflammatory, a dose of laudanum sufficient to induce sound sleep will often, as it were, break

the habit and relieve it. Sedatives, conjoined with stimulating expectorants, such as squilla, ammoniacum, benzoic acid, &c., are often effectual in relieving the coughs of old age; and in these, and what are called nervous coughs, much relief is experienced by administering mild opiates in the form of lozenges, so that they may pass gradually over the neighbourhood of the affected part, in consequence of the slowness with which they are dissolved in the mouth and swallowed: lozenges of sugar, liquorice, or tragacanth, with about two grains of extract of poppies in each, are useful in such cases. Where coughs are symptomatic of inflammatory action, of asthma, &c., they often require modes of treatment which have more particular reference to their exciting causes.

Coulter (Lat. *culter*). In Agriculture, an iron blade or knife inserted into the beam of a plough, for the purpose of cutting the ground and facilitating the separation of the furrowslice by the ploughshare. [PLOWH.]

Coumaric Acid. An organic acid derived from coumarin, by the action of alkalis. It crystallises in lustrous colourless plates.

Coumarin. A crystalline odoriferous principle extracted from the Tonka Bean, which is the seed of the *Dipteris odorata*.

Council (Lat. *concilium*). In Church History, an assembly of prelates and other spiritual persons for the regulation of ecclesiastical matters. Such councils are either national or oecumenical; the latter being those in which the whole body of the clergy throughout the world is represented, and are convened for the settling of points of universal interest.

The Roman Catholics hold that the decisions of oecumenic or general councils are infallible, and for the most part allow their superiority to the popes themselves. This superiority was first asserted at the council of Pisa, in which the two reigning anti-popes were deposed; it was confirmed by the councils of Constance and Basel or Basle. Since that time the popes have been very unwilling to convene a general council, and that of Trent is the only one that has assembled in later times.

Some Protestants allow the authority of general councils in matters which do not contradict Scripture, and attach great importance to the four first councils; viz. of Nice, Constantinople I., Ephesus, and Chalcedon. But they maintain that a general council can only be called by a temporal prince, while this prerogative is assigned by the Romanists to the pope.

Council, Privy. The principal council belonging to the king of England. In its origin it appears as a small permanent committee, or minor council, consisting of members selected by the king himself out of the great council of the kingdom. The latter body is supposed to have been originally composed of all the immediate tenants of the crown; and it was occasionally summoned as late as the reign of Richard II., and seems then to have comprised nearly all the prelates, nobles, and

bannerets of the kingdom *et autres sages*. When the privy council was formed out of it, has not been ascertained. It appears in early rolls of parliament as the permanent or continual council; and as its powers under the Plantagenet kings were very extensive, so parliament exercised considerable influence in controlling the appointment of its members, although always vested in the crown as an essential prerogative. The privy council under these sovereigns usually consisted of the five great officers of state, the two archbishops, and from ten to fifteen other individuals, spiritual or temporal. It sat continually as a court, both to expedite the executive part of the administration, and to provide equitable relief in cases submitted to it, thus controlling the courts of common law. (Sir F. Palgrave's *Essay on the Original Authority of the King's Council*, 1834; and the Preface to the *Records of the P. C.*, edited by Sir H. Nicolas.) There were also under the Tudors councils, portions of the privy council, exercising like powers in various parts of England. The increasing power of parliament on the one hand, and the extended equitable jurisdiction of the lord chancellor on the other, gradually encroached upon the ancient dignity and importance of both the councils. The Star Chamber and Court of Requests, dissolved in the reign of Charles I., were both committees of the privy council.

Privy councillors are made by the king's nomination, without patent or grant. Their number, having greatly increased under the Tudor princes, was restricted by Charles II. to thirty; but soon became indefinite again, and has so continued. They are entitled *right honourable*. No privy councillors attend except such as are specially summoned. The privy council continues in office six months after the demise of the crown, unless sooner dissolved by the successor. The separation of the functions of the privy council from the more important political duties of the Cabinet, which is in truth only a committee, without recognised legal powers, of the Privy council, seems to have been chiefly effected in the reign of William III.

The jurisdiction of the privy council is of several sorts: 1. The king in council may issue proclamations binding on the subject, if consonant to the laws of the land. He issues also orders in council for the temporary regulation of various matters relating to trade and international intercourse. 2. The privy council has power (which, however, has been long out of use) to enquire into offences against government, and commit offenders to take their trial according to law. 3. Appellate jurisdiction in the last resort from all his majesty's dominions, except Great Britain and Ireland, is vested in the privy council. By 3 & 4 Wm. IV. c. 41, enlarged by 6 & 7 Vict. c. 38, a judicial committee of the privy council is constituted, to which are entrusted appeals from the Ecclesiastical and the Prize and Admiralty Courts,

and courts in the plantations abroad, and all other appeals which might previously have come before the king in council. The judicial committee may direct issues of fact to be tried at common law. The lord president of the council is the fourth great officer of state. The office must probably have been cotemporary with the origin of the council itself; but the title is comparatively recent. It was created by Henry VIII., and revived by Charles II. in favour of the earl of Shaftesbury. Of late years the business of his office has been greatly increased by the control vested in it over the grants for public education.

Council of State. A political and judicial body of very indefinite powers in the French monarchy, both before and since the Revolution. As reorganised by Napoleon I. it became the most important body in the state. It now, under the second empire, consists of members of the imperial family, nominated by the crown: a president, vice-president, presidents of sections (which are six: justice, contentions, home affairs, public works, war, finance); forty to fifty ordinary and nearly forty extraordinary councillors.

Counsellor (Lat. *consiliarius*, Fr. *conseiller*). In Law, a person retained by a client to plead his cause, who is also said to be counsel for him. For the regulations by which the admission to practise as a counsellor is restricted in England, see **BARRISTER**.

Count (Lat. comes, a companion). A title of dignity in most of the Continental states of Europe, equivalent in rank to the British earl and the German *graf*. Under the Byzantine empire, the forty-three great military commanders were styled *dukes* (duces); of these ten were known by the higher title of *counts* or companions. (Gibbon, *Roman Empire*, ch. xvii.) Under the first two races of the Frank kings, his title of *count* was given to officers of various degrees, and was at first attached to the office, and not to the person; but in the progress of time, when feudalism had introduced inheritance instead of election as a fixed rule in succession, it became subject to the same law as the higher titles of kings and dukes, and conferred hereditary privileges on its possessor. [FEUDALISM.] The term *count* has in most of the states where it is in use degenerated into a mere title, to which no political importance is attached. Though the title *count* has never been introduced into Britain, the wives of earls have from the earliest period of its history been designated as *countesses*.

COUNT. In Law. [DECLARATION.]

Counter Mark. In Numismatics, a stamp frequently seen on ancient coins, often obliterating part of the inscription or the impression. The counter mark is generally a figure or inscription; and some antiquaries have considered that its use was designed to increase the value of the money; others that it was only struck on money taken from an enemy.

Counter-tenor. In Music, the same as CONTRALTO.

COUNTERFORT

Counterfort (Fr. *contresfort*). In Architecture, a buttress, or pier, built against or at right angles to a wall to strengthen it, so as to enable it to resist a particular thrust.

Counterguards (Fr. *contre-garde*). In Fortification, are small ramparts with parapets and ditches, to cover some part of the body of a place, to which they are made parallel. They are generally made before the bastions, sometimes before the ravelins.

Are mines or galleries excavated by the defenders of a fortress, to intercept the mines and destroy the works of the besiegers. [MILITARY.]

Counterpart (Fr. *contrepartie*). In Law, when the parts of an indenture are interchangeably executed by the several parties, that part which is executed by the grantor is termed the *original*, and the rest are *counterparts*. If each part is signed by all parties, they are duplicate originals.

Counterpoint (Fr. *contrepoint*; Ital. *contrapunto*). In Music, the art of writing music in several distinct parts. The name is derived from the circumstance of the notes being placed one against or over the other on the score. [MUSIC.]

Counterpoise. In Mechanics, a mass of metal connected with an instrument or machine, either for the purpose of giving steadiness, or diminishing the pressure on some particular point, as, for example, the pressure of the pivots of a transit-instrument on its supports.

Counterproof. In Engraving, an impression obtained from another impression, whilst it is still wet from the cop, in which the design is in the same direction as in the plate itself. It is made chiefly for the sake of investigating the state of the plate; and of some prints the counterproofs are more valuable than the prints, where the drawing from the picture has not been reversed on the copper; these, however, are amongst the curiosities of the trade of print-sellers.

Counterscarp (Fr. *contrescarpe*). In Fortification, the wall of the ditch on the side farthest from the body of the work.

Countersign. A watchword given daily by the commander of an army, in order that friends may be distinguished from enemies by their knowledge of it. Before an enemy, sentries require the countersign from everyone who approaches their post.

Countersignation. In Diplomacy, the signature of a public officer to the charter of a king, prelate, &c. by way of certificate. *Obtulit, recognovit, relegit et subscripsit*, are common additions, in charters of the middle ages, to the name of the countersigner.

Country. In Mining, the name given by miners to the rock enclosing a mineral vein containing ore. Thus a granite or a slate country are spoken of according as the vein occurs in granite or slate.

County. A county is in England that district of territory which was anciently subject

COUNTY

to the government of an earl or ealdorman, from whose Latin title *comes* the term is derived. The English word corresponding to county was *shire*, meaning division, which is therefore not applied to such counties as were originally distinct sovereignties; such as Kent, Essex, Sussex, Middlesex, Suffolk, Norfolk.

The division of the kingdom into counties, which, in common with many other of our earlier institutions, is commonly attributed to Alfred, though it was probably of a date far anterior, was in ancient times chiefly of use in marking the limits of different jurisdictions. To each county belonged a county court, which it was the duty of the thanes and other freeholders to attend and do suits at, though it seems the thanes only took part in the administration of justice. Such court was originally held by the earl and bishop, the latter assisting in respect of the ecclesiastical jurisdiction belonging to the court; or in their absence by the sheriff, upon whom the right to preside in the county court, either in person or by deputy, as well as the other civil functions of the earl, have long since devolved. Considered in its judicial character, the county court was the great court baron or civil court of the county, and was originally competent to the trial of almost all civil actions arising within such county. The criminal jurisdiction belonging to the county, which is now vested in the magistrates at quarter sessions, was anciently exercised by the sheriff in his tourn. [TOWN.] The boundaries of a county serve also to mark the limits of the jurisdiction, both civil and criminal, which other courts or judges exercise within each county severally by commission from the crown [VENUE]; and within these limits also are confined the ministerial functions of the sheriff as executor of the writs awarded by either of the great courts.

The division into counties is also for some purposes, particularly that of representation in parliament, political; and it is in the county court that the election of members of parliament takes place, and that other political acts of the men of the county are done; for county meetings convened and presided over by the sheriff are, properly speaking, holdings of the county court. What has been said of counties in England applies without qualification, save as to the time of the institution, to Wales, and, with very little qualification, to Ireland and Scotland; the most important point of difference being the greater extent of the jurisdiction and power of the sheriff in the latter country. There are in England 40 counties, in Wales 12, in Scotland 32, and in Ireland 32.

A County Palatine, of which description there are now two in England, viz. Durham and Lancaster, is a county in which all jura regalia, i. e. the whole rights of sovereignty in judicial matters, belonged to the earl of such county; but these privileges are now reduced to the possession of courts of their own, corre-

sponding in their local jurisdiction to the Queen's courts at Westminster, whose jurisdiction is not excluded by theirs, and whose writs may be so framed as to run within the limits of the county palatine.

County Court. The County Court properly so called is a court baron, not of record, for civil causes, held by the sheriff in each county. This court could formerly hold pleas where the debt or damage was under 40s., except by virtue of the writ called of *justicies*, which was a special precept to the sheriff to do justice between parties in the same manner as it might be done in the courts of Westminster. But by the 9 & 10 Vict. c. 96, a great extension of jurisdiction was given to the county courts; and they were completely remodelled. That statute has been amended by several subsequent statutes, down to 19 & 20 Vict. c. 108, by which the expense of these courts, hitherto borne by the suitors, was almost wholly transferred to annual vote of parliament. It may be generally said that they have exclusive jurisdiction in cases of debt or damage up to 20*l.*, concurrent up to 50*l.*, and by consent to any amount: subject, however, to certain provisions for removal to the superior courts where required. Many other branches of jurisdiction (equitable, insolvent, &c.) have been by degrees conferred on these important tribunals.

County Rate. [RATH.]

Couple of Forces or Pressures. In Statics, a *couple of pressures* (or *forces*) denotes two equal pressures having precisely opposite directions, but applied at different points of a body. According to the ordinary method of the composition of parallel forces, the resultant of such a system would be a parallel force having the intensity zero, and applied at an infinite distance. In reality, two such forces have no single resultant; their tendency being to produce rotation about an *axis* perpendicular to their plane. Couples, therefore, require a distinct treatment. The theory of couples, their composition, resolution, &c., was first given by Poinso (Éléments de Statique), and now constitutes an essential branch of statics. The distance between the parallel forces is called the *arm of the couple*, and the product of either force into the arm the *moment of the couple*. It can be readily shown that the statical effect of a couple is unaltered by transportation to a parallel plane, or by any variation in the magnitude and direction of its forces and arm, provided the moment remains the same. On this account, a couple, like a simple force, may be conveniently and perfectly represented by a line OA drawn from any origin O perpendicular to its plane, having a length OA proportional to its moment, and a direction such that, to an observer at A, looking towards O, the rotation which it is the tendency of the couple to produce shall appear to be direct like the hands of a clock. Such a line, limited in length and definite in direction, is called the *moment-axis* of the couple, in order to distinguish it from the *rotation-axis*, which is unlimited in length and simply indi-

cates the direction of the plane of the couple. This mode of representation being adopted, the composition and resolution of couples follow the same laws as those of concurrent simple pressures. Thus, if we regard the moment of a couple as positive or negative, according as the rotation would be direct or retrograde, we may say: *The resultant of two or more coaxial couples is another coaxial couple whose moment is the algebraical sum of the moments of the components.* Again: *The moment-axis of the resultant of any two couples is the diagonal of the parallelogram whose sides are the moment-axes of the components.* The above two properties of couples being established, the general problem of the composition of any number of pressures acting on a body in different directions becomes greatly simplified. [FORCES, COMPOSITION AND RESOLUTION OF.]

Couple of Rotations or Angular Velocities. Two equal and opposite rotations around parallel axes. The term was introduced by Poinso (Théorie de la Rotation des Corps), who first fully investigated the composition and resolution of rotations. A couple of rotations is easily shown to be equivalent to a translation of the whole body in a direction perpendicular to the plane of the rotation-axes, with a velocity equal to that which either axis possesses in virtue of its rotation about the other. The common velocity of all points of the body is expressed by the product of either of the equal angular velocities into the distance between the axes. This distance is called the *arm of the couple*, and the product its *moment*. A couple of rotations, therefore, may be represented perfectly by a single line, exactly as in the case of a couple of pressures; and the composition and resolution of both kinds of couples follow precisely the same laws. Velocities of rotation and translation are, as it were, reciprocal—a couple of either is equivalent to one of the other.

Coupled Columns. In Architecture, columns half a diameter apart. The façade of the Louvre, and St. Paul's Cathedral, contain some of the best examples of this style of intercolumniation.

Couplings. In Machinery, this term is applied to any contrivance for connecting or disconnecting the different parts of a machine, and particularly for effecting the longitudinal connection of shafts. Hook's Joint (Dictionary of Science) is one of the most ingenious contrivances of this kind. (Buchanan's Practical Essays on Mill Work &c., with Additions, by Tredgold and Rennie.)

Coupling Box. A strong iron cylinder, by which the shafts of machinery are connected.

Couriers (Fr. *coursier*, from *courir*, Lat. *currere*, to run). A name given to the bearers of public despatches or private intelligence by express. The employment of couriers is of great antiquity. By the Persians they were styled *ἄγγελοι*, by the Greeks *ὑποπόδρομοι*, and by the Romans *cursores*. The duties of the ancient couriers seem to have been the same as

COURSE

those of the moderna, and were performed chiefly on horseback. In the middle ages couriers were known by the appellation *trot-tarii*, or *trotters*; and hence perhaps originated the English term *running footmen*, of whom history makes mention in the seventeenth and eighteenth centuries.

Course (Lat. *cursus*). In Architecture, a continued level range of stone or brick of the same height throughout the range of the elevation of a building.

Course. In Navigation. The angle which the ship's track makes with all the meridians between the place left and the place arrived at.

Course of Orops. [ROTATION OF CROPS.]

Couriers, Couriers (Lat. *runners*). An order of birds, including those which are disabled from flight by the restricted development of the wings, but which possess superior powers of running from the compensating size and strength of the legs: the ostrich, rhea, emu, and apteryx are examples of this order.

Courses. On Shipboard, are the sails sustained by the lower masts, viz. the foresail, mainsail, and spanker. They are the largest and most powerful sails on board.

Court Baron. A Court Baron, so called either from the lord or baron who presided over it, or from the freemen, in ancient times also called barons, who were its suitors and judges, was a court having its origin apparently in notions of a patriarchal jurisdiction, properly and in the first instance incident to every manor, in which it was held by the lord of the manor or his steward, who, assisted by the freeholders of the manor, there decided on the purely civil controversies which arose between them. A court baron also belonged to every HUNDRED and COUNTY [see those titles]; and in many cases also to particular franchises or lordships, which might include several manors. Courts baron, from the inferiority of their judges, and from the defects of their jurisdiction, which a party might defeat by removal of the cause to a higher tribunal, have long fallen into disuse; except in manors of ancient demesne, where the jurisdiction was, and in some respect still is, in the first instance exclusive, the lord of such manors having once been the king; and except in manors containing land of copyhold or customary tenure. [COPYHOLD.]

Court of Enquiry. In Military Law, is held under the crown's prerogative (as established in 1820 in the case of Colonel Horne) to enquire into the conduct of military or naval men in special cases; distinct, therefore, from martial. Among some of the most recent on record are: that on the convention of Cintra, 1808; that on the riots at Bristol, 1831. Proceedings are conducted by the judge or his deputy, before a tribunal nominated by the crown.

Court Plaster. Black silk varnished over with a solution of isinglass, which is often perfumed with benzoin.

COURTS OF JUSTICE

Court, Supreme, of the United States. The highest judicial authority in that commonwealth, consists of seven judges, nominated by the president during good behaviour with the advice and consent of the senate. Its original jurisdiction is defined by the constitution, and extends to a variety of cases in which the provisions of the constitution itself, or federal interests, come in question: including suits to which the federation is a party; suits between two or more states; and between a state and foreign states. It has also an extensive appellate jurisdiction.

Courts Martial. In Military Law, derive their authority from the annual Mutiny Act, which empowers the crown to issue commissions to commanders of bodies of troops to convene, and authorise inferior officers to convene, such courts. Courts martial are: 1. General; 2. District or Garrison; 3. Regimental, and for bodies less than a regiment. In general courts martial, the judge-advocate-general settles the charges against the accused. In other courts martial, this is done by the convening officer. The charges are for offences against some article of war or clause of the Mutiny Act. The question of guilty or not guilty, or any other finding of the court, is decided by a majority of voices: it is considered that by the custom of the service the president has no casting vote, and that equality of votes implies acquittal. But the president has a casting vote as to the sentence. The sentences of general courts martial are subject to confirmation by the crown. General courts martial alone are competent to try commissioned officers, and certain civilians subject to the Mutiny Act; or to pass sentences of death or penal servitude. Naval courts martial are general only. (19 Geo. III. c. 17, sec. 9, and 22 Geo. III. c. 23.)

Courts of Justice. Courts of justice are divided by the rules of English law into courts of record and not of record. The former have power to make up their acts and judicial proceedings in the form technically called a record, as evidence of their judgment. All courts having power to fine or imprison are said to be impliedly courts of record; but this seems questionable.

The courts termed Superior are divided into those of Law, Equity, Ecclesiastical, Maritime, Prize or International, and Courts of Appeal and Error. They are:—

Three Superior Courts of Common Law. [COURTS, SUPERIOR.]

Superior Courts of Equity. [CHANCERY.]

The Ecclesiastical Courts. [ECCLESIASTICAL COURTS.]

The Court of Admiralty. [ADMIRALTY.]

The Prize Court. [ADMIRALTY.]

The Courts of Bankruptcy. [BANKRUPTCY.]

The Courts of Error and Appeal are:—

1. The Exchequer Chamber, from the Superior Common Law Courts. [EXCHEQUER CHAMBER.]

2. The Privy Council, and Judicial Com-

COURTS, SUPERIOR

mittees of the Privy Council, which are Courts of Appeal from the Ecclesiastical Courts, Admiralty, and also from the decisions of various Colonial Judicatures.

3. The High Court of Parliament. [PARLIAMENT.]

To the courts above mentioned must now be added the Courts of Probate, Divorce, and Matrimonial Causes, to which a large part of the jurisdiction of the Ecclesiastical Courts has recently been transferred. [PROBATE; MARRIAGE.] Inferior Courts were formerly very numerous, but their jurisdiction has now for the most part been transferred to the County Courts.

Courts, Superior. The three superior common law courts of England are the Courts of Queen's Bench, of Common Pleas, and of the Exchequer. [See those separate heads.]

For several centuries (formerly by means of various fictions) these three courts have exercised a concurrent jurisdiction in all personal actions [ACTIONS]; and the practice of all three is, in material points, the same. The different branches of jurisdiction of the three superior courts are: 1. That of the full court in *banc*, usually during term, when four judges sit together in each; 2. Of the Practice or Bail Court (created by 1 Wm. IV. c. 70, s. 1, in which a single judge disposes of some less important matters of business); 3. Of a single judge at chambers, where also points of minor importance in the conduct of a cause are decided, and directions given; 4. Of the masters of each court, officers to whom various matters of fact, as computations, &c., are referred; 5. Of the judge at Nisi Prius and on the circuit for the trial of issues in fact; 6. Of the sheriff in each county, who may be considered as an officer of the superior courts for the purpose of trying issues directed to him under 3 & 4, Wm. IV. c. 42.

The course of proceeding in the superior courts is either formal or summary. Formal proceeding, in personal actions, is the regular course of a trial, whether the issue, or question tried, be one of fact or law. The party complaining, or plaintiff, having brought the defendant into court in person, or constructively, by preliminary *process*, entitles his *declaration*, or the form of statement of his grievance [PLEADING], as of one of the three courts, the same in which the writ for commencement of the action is said to be *returnable*. The defendant then pleads; and all the subsequent pleadings, or preparatory statements in writing, are entitled of the same court: in which also the record, or parchment roll containing the authentic entry of the whole proceeding, is made up. The question eventually raised between the parties will turn out to be either of law, or of fact. The former being raised on what is termed a *demurrer* [PLEADING], is argued at Westminster before the full court, and the judgment in law is conclusive of the issue. If the question be of fact, it must be

COURTESY

tried by a jury. If the pleadings are dated at London or in Middlesex, as in *local* actions they must be if the question arise in those districts, and as in *transitory* actions they may be in all cases [PLEADING], the jury will be summoned accordingly, and the case tried before a judge of the court in which the action is brought, at Nisi Prius [see that head], either during term or in the sittings after term. If, on the other hand, the date, or *venue*, as it is termed, be in any other county, the parties proceed to trial at the assizes (the plaintiff bringing down the record from Westminster, by which means it is in his option to proceed to trial or not). In this case a jury is summoned in like manner before the judges of assize, by virtue of their commission of oyer and terminer. In some special cases, trial at bar is granted on application; in which case the cause is tried by a jury before the full court, at such time as the court may fix for convenience. If a party imagines himself to have grounds for being dissatisfied with the result of a trial, as, that the judge has summed up the evidence improperly to the jury, or that material testimony has been illegally rejected, he may move the court at Westminster for a new trial, or to set aside the verdict, according to the circumstances of the case; and such motion is made before the full court in term. On the issue of the trial judgment is awarded, declaring that the plaintiff either has, or has not, entitled himself to the remedy prayed; and costs are given with the judgment; after which the successful party may issue out execution, unless there be an appeal by writ of error, which only lies on matter of law arising on the face of the proceedings.

Summary proceedings are of very miscellaneous character; and are by affidavit, motion, rule *nisi* (i. e. unless cause is shown against the rule on a certain day; when, if no cause, or insufficient cause, is shown, the rule is made absolute, and if made absolute, followed by demand of performance, and this performance enforced by means of attachment for contempt of court). By these means the courts have extensive authority to give directions and enforce conditions during the progress of a suit. Among summary proceedings may also be enumerated the leave given, on motion, to amend various formal defects in pleadings.

Courtesy (Fr. *courtoisie*, Ital. *cortesia*). It was at the courts of princes and great feudatories that the minstrels and troubadours of the middle ages especially delighted to exercise their art; and it was there, also, that the peculiarities of chivalrous life and manners were chiefly exhibited. Hence *courtesy* was a general term, expressive of all the elegance and refinement which the society of those times had attained; in fact, it was synonymous with all the gentler parts of chivalry itself; and in this sense it is used both by the early trouvères and romancers, and also by poets of a later age.

COUSERANITE

when affecting the use of chivalrous language, as in the first lines of the great poem of Ariosto:—

*Le donne, l' cavalier, l' arme, gli amori,
Le cortesi, l' audaci impresso io canto.*

The transition from this wider meaning to that in which it is now employed is obvious enough. It may be sufficient to refer to the very ingenious theories of Signor Rossetti respecting the secret meaning attached to this word as well as to others of frequent occurrence in the poems of the Italian canonieri of the thirteenth and fourteenth centuries. (*Inferno di Dante*, 1827, vol. ii. p. 430 &c.)

Couseranite or **Couseranite**. A silicate of lime and alumina with potash and soda, the principal localities of which are in the department of Ariège (formerly Couserans) in France, where it is found in a black schist in short square or octagonal prisms. It is, also, met with in rounded, bluish-black crystals, near Pouzac, on the right bank of the valley of Bagnères-de-Bigorre.

Cousinet (Fr. a cushion). In Architecture, the crowning stone of a pier from which the arch springs, or that which lies between the capital of the impost and under the sweep of the arch; its bed is level below and inclined above, receiving the first rise or the spring of the arch. This word is also used for the ornament in the Ionic capital between the abacus and the echinus, which serves to form the volute, and is thus called because its appearance is that of a cushion, or pillow seemingly collapsed by the weight above it: it is bound by a strap or girdle, called the *balteus*.

Covade. [OBBAAH.]

Covariant. A quantic so derived from a given system of quantics as to be equal, to a factor *præ*, to the quantic similarly derived from the linearly transformed system of quantics, and that in virtue of the *same* relation between the new and old variables. If the linear transformation be unimodular, we may say that a quantic is a covariant when the operations of derivation, by which it is obtained from the given system, and linear transformation are *commutative*. This characteristic property is also expressed, briefly, by saying that the relation of a covariant to the system of quantics is unaffected by one and the same linear transformation of all the facients. The given system of quantics may, of course, consist of a single

Mr. Cayley, the discoverer of covariants, has in his more recent researches (*Phil. Trans.* 1864) given another definition which we will illustrate by an example. Let $(a_0, a_1, a_2, a_3)X(x, y)^3$ be any binary cubic; then the results of the two operations

$$y \frac{d}{dx} \text{ and } a_0 \frac{d}{da_1} + 2a_1 \frac{d}{da_2} + 3a_2 \frac{d}{da_3}$$

performed upon it are obviously identical, and a similar relation will be true for all binary quantics, so that we may indicate by $\left[y \frac{d}{dx} \right]$ the

COVENANT

operation which when performed upon the coefficients of a quantic is identical with $y \frac{d}{dx}$

applied to its variable part. This being understood, a *covariant* of a quantic may be defined as any function of its variables and coefficients which, like the quantic itself, is reduced to zero by each of the two operators

$$\left[y \frac{d}{dx} \right] - y \frac{d}{dx} \text{ and } \left[x \frac{d}{dy} \right] - x \frac{d}{dy};$$

and an *invariant* as any function of its coefficients alone which possesses the same property. Thus

$(a_0 a_2 - a_1^2)x^2 + (a_0 a_3 - a_1 a_2)xy + (a_1 a_3 - a_2^2)y^2$ is a covariant of the above cubic; it is in fact its Hessian, and $a_0^2 a_2^2 + 4 a_0 a_1 a_3^2 + 4 a_2 a_1 a_3^2 - 3 a_1^2 a_2^2 - 6 a_0 a_1 a_2 a_3$ is an *invariant*, in fact its discriminant.

Covariants are distinguished according to their dimensions in the coefficients of the original quantic as well as according to their degrees in the variables; thus a covariant of the second dimension in the coefficients and of the fourth order in the facients would be termed a *quadrivariant quantic*.

The geometrical applications of the theory of covariants are most important. In general a ternary or quaternary covariant, equated to zero, represents a curve or surface whose relation to a given system of curves or surfaces is of a permanent character and unaffected by any transformation of coordinate axes. Dr. Salmon's *Lessons on the Higher Algebra* will be found to be a useful treatise on the subject; the identity of the above two definitions is established at p. 76 of that work. For further particulars with respect to the formation of covariants, see **HYPERDETERMINANT**.

Cove. This term is applied to the hollow part of a moulding, or to a concave depression on a rectilinear surface.

Cove. An inlet on a rocky coast. It is a term nearly synonymous with *harbour*; the word *cove* being generally, though not always, used when the indentation on the coast is too shallow or narrow to admit first-class vessels.

Covellite, **Covellinite** or **Covellite**. A sulphide of copper, which occurs in the form of a sooty deposit or network, like a spider's web, around the fumaroles of the crater of Vesuvius.

Named after the discoverer, Signor Covelli.

Covenant (from Lat. *convenio*, through Fr. *convenant*). In History, the famous bond of association adopted by the Scottish Presbyterians in 1638. [**COVENANTERS**.]

COVENANT. In Law, an engagement under seal to do or to omit a direct act. Covenants are of many different species, as, in fact and in law, implied and express, &c.; and, according to their subject-matter, or express stipulation, they are binding respectively on the heirs, executors, and assigns, or executors and assigns only, of the covenantor.

COVENANT. Is also a form of action, which lies where a party claims damages for breach of a covenant or contract under seal.

COVENANTERS

Covenanters. The great body of the Scottish people, at the era of the Reformation, adopted the presbyterian faith and polity as established by Calvin at Geneva, and as introduced into Scotland by Knox. But it never succeeded in gaining permanently the affection or countenance of the court. On the contrary, the successive monarchs by whom Scotland was governed from the Reformation in 1560 till the final establishment of presbytery as the national church in 1690, did all in their power to undermine and destroy it. But though, owing to royal favour, episcopacy, or *black prelacy*, as it was called by the presbyterians, occasionally predominated, it was as often superseded by presbytery. The latter, after having been for some time displaced by prelacy, gained the superiority in 1592; from which time till 1606 it was established as the national religion. At this latter period, however, episcopacy obtained the mastery, which it enjoyed for upwards of thirty years. It continued, however, as obnoxious as ever to the great body of the Scottish people; and matters at length came to a crisis. Charles I. having introduced the High Commission Court, and having attempted also to introduce the Book of Canons and the Liturgy or Service Book, public indignation was unequivocally expressed, particularly in Edinburgh, where a very serious tumult took place (July 1637) on a Sunday, when an attempt was made (according to royal proclamation) to read the liturgy in the church of St. Giles. Supplications against the liturgy issued from all classes of the people, and from the great majority of municipal corporations, and were carried by the principal men of the kingdom to be presented to the privy council. These supplications were not attended with success; but the supplicants were not to be driven from their purpose. The most effectual means were adopted to keep up an organised opposition to the royal procedure. Four *tables*, as they were called, were formed. One table consisted of nobility, another of gentry, a third of clergymen, a fourth of burghesmen; thus representing all ranks and classes of the people. There was also a general table, composed of representatives from the four subordinate tables, which received suggestions from these, and decided on what steps it was necessary to adopt. One of their first acts was the production of the *Covenant*; and hence all those who either then or afterwards subscribed it or gave in their adherence to it, were denominated *Covenanters*.

The Covenant to which we now refer, is in many respects a renewal of the Covenant which was subscribed in the year 1580, 1581, and 1590, but so modified and enlarged as to embrace the circumstances under which the church was placed at the crisis under review. It inveighed not merely against popery, as the former Covenant had done, but 'against the danger of the true reformed religion (that is, the presbyterian faith and polity as established in 1592), of the king's honour, and of the public peace of the

kingdom, by the manifold innovations and evils' so generally prevalent. The subscribers also profess, and 'before God, His angels, and the world, solemnly declare, that, with their whole heart, they agree and resolve all the days of their life constantly to adhere unto and to defend the aforesaid true religion.' (See the *National Covenant* appended to the *Westminster Confession of Faith*, p. 483, edition 1815.)

These expressions with many others showed that the persons by whom they were uttered were in earnest, and that nothing could satisfy them but the abolition of the High Commission Court, and the revocation of the canons and liturgy. They insisted on the questions between them and the king being immediately submitted to a free General Assembly of the Kirk and to parliament.

Meanwhile the supplicants repaired from the country to attend a solemn meeting in Edinburgh, at which the Covenant (March 1, 1638) was solemnly subscribed and sworn by the nobility, gentry, clergy, and burghesmen. Commissioners were immediately despatched with copies of it throughout Scotland; and in a few weeks every district of the country, with some partial exceptions, submitted to the Covenant.

Charles, seeing the formidable position and influence of the Covenanters, was at length willing to recall the liturgy and the canons, and to make considerable concessions for the sake of peace. But it was too late: nothing would satisfy the Covenanters but the extirpation of prelacy. Nay, so far did they carry their condemnation of the bishops, that they had not only preferred an accusation against them as the authors of the innovations, but had, meanwhile, applied for an interdict, prohibiting them from having a seat in the privy council. The prelates, indeed, finding that their influence was nearly gone, voluntarily withdrew from the council; and the king, after much temporising and intrigue, found himself obliged to agree to the meeting of the General Assembly on the terms which the Covenanters had proposed. The Assembly met at Glasgow in November, and continued its sittings (for thirty days) as its inalienable right, even though the royal commissioner, the marquis of Hamilton, had meanwhile declared the meetings dissolved. It not only annulled the canons, liturgy, the High Commission Court, and other innovations, but it abolished episcopacy itself, as having been from the first both illegal and unscriptural. (*Acts of Assembly*, 1638.)

The proceedings of this assembly were so obnoxious to Charles that when the Supplication voted at the conclusion of its meetings was presented to him he declined to return any answer. This injudicious conduct brought matters to a crisis. Both parties prepared for war, a step which the Covenanters, who always professed the greatest loyalty, adopted with reluctance. So devoted, however, were the people to what they regarded as a righteous cause, that the expense on the side of the

COVENANTERS

Covenanters was defrayed by a general voluntary assessment. In raising both men and money, the clergy took an active part; and contributions for carrying on the war were levied by them from their respective flocks to an extent scarcely credible. Of the hostilities that ensued it is unnecessary here to say more than that, though they gained the only battle that was fought, they lost no time in making proposals of peace. These proposals were accepted by the king; and a treaty was concluded (June 1639) four months after the commencement of the war. Of this treaty, the most important clause was that, as the king would not ratify the enactments of the Assembly of Glasgow, and as the Covenanters would not annul them, a free General Assembly should be held in the ensuing month of August, and a parliament immediately afterwards; to the decision of which courts every dispute between the contending parties was to be referred. This Assembly met accordingly; but its proceedings displeased the king more, if possible, than those of its predecessor; and fearing that the parliament might exhibit a similar spirit, he lost no time in proroguing it. But nothing could arrest the march of public sentiment; and the parliament which met in June 1640, every enactment of the General Assembly respecting the Covenant and Presbytery became the law of the land.

Thus the Covenanters, after a struggle of three years, saw their favourite ecclesiastical polity established, and the validity and authority of the Covenant, recognised by the legislature. Their history from this date becomes that of the Presbyterian church in Scotland, and is interwoven with the annals of their country. [CAMERONIANS.] Charles, offended with the triumph of the Covenanters, again declared war against them; but after a short campaign, unfavourable to the royalists, peace was restored (1641). When the civil war broke out in England, the Covenanters, on the repeated and urgent application of the parliament, made common cause with them, and took up arms for the third time against royal authority. But along with a civil league the Scots succeeded (1643) in carrying a religious covenant, known in history under the name of the *Solemn League and Covenant*; the main object of which was to accomplish uniformity of religious doctrine and church government in both kingdoms. Nor was this object long in being, so far, attained; a presbytery, as it existed in Scotland (having obtained the sanction of the famous Assembly of Divines at Westminster, 1643-9, and having been afterwards ratified by the English parliament), was recognised as the national church of both portions of the empire. Presbytery, however, was in England rather an experiment than a permanent institution, and it rapidly declined, having been, to a considerable extent, superseded by Independency. At the Restoration episcopacy triumphed over both these forms, and has since been retained in the Established Church

COW-KEEPER

of England. By a sweeping Act, called the *Act Recissory*, passed in 1661, all the parliaments that had been held since 1640 were declared null and void; thus rendering invalid those Acts, in confirmation both of the Covenant and of presbytery, to which the late king had assented, and which Charles II. himself had sworn to maintain. From this period the Covenant may date its decline. It continued, indeed, to be regarded as sacred by those who would submit to no compromise, and who, in consequence, were objects of persecution during the reigns of Charles and his brother James. Nay, so far did some of these parties carry their opinions, that they did not regard any person entitled to homage as king unless he had *covenanted*, or affixed his signature to the Covenant. The party by which such a principle was professed are known in history under the name of *Cameroniens*, a body which, though now much reduced in numbers and importance, and who have moderated or changed their sentiments on this subject as well as on others, still exist in Scotland as a distinct religious sect. [CAMERONIANS.] At the Revolution, when presbytery was revived in Scotland and established as it now obtains, no mention was made of the Covenant either in the General Assembly or inferior courts, and it now exists only as a matter of history.

Covered Way. In Fortification, a space left between the glacis and the edge of the ditch all round the work. The glacis forms its parapet; it is provided with a banquette for musketry defence, and is often palisaded to prevent an enemy taking it by a sudden rush. Here the garrison assemble before making sorties. It is generally about eleven yards broad.

Covered Sine of an Angle. The *versed sine* of the complementary angle.

Coverets. In Ornithology. The *lesser coverets* (*teectrices primæ*) are small feathers which lie in several rows on the bones of the wings. The *greater coverets* (*teectrices secundæ*) are the feathers that lie immediately over the quill-feathers and the secondaries. The *under coverets* are the feathers that line the inside of the wings.

Coverture. In Law, the legal condition of a married woman. [MARRIAGE, LAW OF.]

Covey (Fr. *couvée*, a brood, from *couver*, to hatch). An old bird with her young ones; but generally used to designate a number of partridges or other game. It also in some countries signifies a cover for game.

Cevin. In Law, a compact between two or more, to deceive or prejudice others in certain cases; as, if tenant for life or in tail conspire with another party, to the intent that such party may recover lands held by the tenant to the prejudice of him in reversion.

Cow-keeper. A person whose business it to keep a stock of cows for supplying the public with milk and cream. The principal cow-keepers of the metropolis have their esta-

COW-POX

blishments in the suburbs, where they are connected with pasture fields, in which the animals may be turned out a portion of nearly every day throughout the year. The cows are fed in the house with grains, hay, and other kinds of nourishing food; and as the animals get air and exercise, their milk may be considered wholesome. There are many cow-keepers, however, in the metropolis, who keep cows in confined back houses, and even in dark cellars; and, while they feed them with rich food, give them no exercise at all: hence the milk of such cows cannot be considered as wholesome.

Cow-pox. This disease was proposed in the year 1798 as a substitute for, and preventive of, the small-pox, by Dr. Jenner; and subsequent experience, as well as the extent to which the inoculation of it, or *vaccination*, as it is called, is carried throughout the civilized world, furnish well-grounded hopes of the ultimate extinction of one of the severest visitations of the human race. Small bluish vesicles, surrounded by inflammation, elevated at the edge and depressed in the centre, and containing a limpid fluid, occasionally appear upon the teats of the cow, the animal being at the same time somewhat indisposed; a similar disease is transferable under certain circumstances to the hands of the milkers; and persons who had so received it were found to be in many instances unsusceptible of small-pox, both natural and inoculated. There is a disease of the horse's heel called *grease*, which appears to have produced similar effects upon the hands of farmers, and is perhaps the origin of the cow's disease: but it is from the latter animal that the *matter* is most certainly effective, and from which it is transferred to the human race, where it produces similar vesicles; and the fluid of these may again be transferred with the same effects from one human subject to another. Whether by continuous circulation through human subjects the *virus*, as it is called, gradually loses its preventive efficacy, is an important question, and one upon which there are differences of opinion; but it would probably be more safe if more frequently derived from its original source upon the cow's teat. It seems useless here to discuss the various objections which have been raised, and the suspicions which have been thrown out against the permanent efficacy of this preventive, since the most extended and unbiassed experience of the most skilful observers seems amply to have proved that *when the vesicle has gone through its regular stages*, the person is afterwards, during the whole period of life, unsusceptible of natural and of inoculated small-pox, the exceptions to this statement being so few as either to be referable to imperfect vaccination, or to idiosyncrasy; and though it is not pretended that cases of small-pox after vaccination are as rare as of small-pox after small-pox, yet it is well known that the latter do occur, and, in short, that there is no rule without exceptions. In doubtful cases vaccination should always be repeated; and as no

COW-TREE

inconvenience results from a repetition of its inoculation, and the disease is not infectious by effluvia, it may be performed at certain intervals or may even be tested as to its efficacy by *variolous* inoculation; although to the latter there are certainly serious objections, if we look to its ultimate extermination. In inoculating patients for the cow-pox the matter should be taken from a healthy child, at about the sixth or the eighth day, at which time the vesicle is well formed: and it should be immediately transferred upon the point of the lancet from the vesicle to the arm, and inserted by a small oblique puncture under the cuticle, one place in each arm being quite sufficient. If this direct mode cannot be followed, the virus intended for inoculation may be transferred between two pieces of plate glass, one of which is slightly indented for its reception; when slid over each other they are air-tight, and the edges may be secured by a strip of moist gold-beater's skin, or very thin bladder. If it is necessary to moisten the virus, this should be done with as small a portion as possible of tepid water, not exceeding the temperature of 100°. Lancet points which have been *armed*, as it is called, cannot be long depended upon, and are apt to be rusted and to irritate the arm. About the third day after inoculation the puncture generally becomes red and elevated, but the periods of its incipient progress are very uncertain; it then continues to enlarge and become vesicular; and is in full perfection about the eighth or ninth day, at which period also the surrounding circle of inflammation or *areola* is at its height. About the eleventh or twelfth day this declines, and the centre of the vesicle becomes brown, and gradually dries up into a dark-brown circular scab, depressed in the centre. During the progress and scabbing off of the vesicle great care should be taken to avoid all external injury; all irregularities in its progress should also be carefully watched; and if much inflammation comes on spontaneously two or three days after inoculation, and especially if suppuration ensues, the probability is that the operation has failed; and in all cases where there is the least doubt, the inoculation should be repeated, although, if one of the vesicles has gone through the above described progress, the failure or irregularity of the other is of less consequence. The cow-pox is seldom attended by any symptoms requiring medical aid; but generally there is a slight drowsiness and febrile symptoms, with some restlessness, and occasionally sickness, about the second and third days; but these symptoms are immaterial to the preventive efficacy of the virus, which can only be judged of by the appearance and progress of the vesicles, to which therefore it is necessary to pay close attention.

Cow-tree. The Palo de Vaca of South America, *Brostium Galactodendron*, sometimes called *Galactodendron utile*. The name is also applied to *Tabernaemontana utilis*, *Clusia Galactodendron*, and *Ficus Sausseuriana*.

Cowhage, Cowitch. This term is generally applied to the hairs or spiculae which cover the seed pods of the *Mucuna pruriens*, a climbing perennial plant, which is a native of the West Indies. An electuary formed by dipping the pods into treacle, syrup, or de-spumated honey, and then scraping them, has long been used as a vermifuge; but it is often a very troublesome remedy, from the excessive itching which it produces when it touches the unprotected skin, and there are other more effectual means of expelling worms.

Cowries. Small shells brought from the Maldives, which pass current as coin in smaller payments in Hindustan, and throughout extensive districts in Africa: 100 are equivalent to a penny.

Coxswain. In Maritime language, is the steersman in a boat. He has the command for the time being of the boat's crew.

Ceyx. A Rodent quadruped; the *myopotamus* of zoologists. [NUTRIA.]

Crab. [CANCER.]

CRAB. A machine for raising weights, consisting of a horizontal barrel, usually turned by a winch handle, and having a rope wound round it, which, when the weight is to be raised to a greater height than the machine, passes over a pulley fixed on the scaffolding. [WINDLASS.]

Crabro (Lat. *a hornet*). A genus of Hymenopterous insects, belonging to the section *Aculeata* or sting-bearers, and to the subsection *Fossoris* or burrowers. The hornet (*Crabro vulgaris*) is the type of this genus, which is now raised to the rank of a family (*Crabronidae*), including two groups of subgenera. In one of these groups all the species have their fore-legs provided with strong spurs, for the purpose of excavating in decayed wood, or burrowing in sand, in order to form cavities, in which their eggs are deposited; the insects of the other section have the fore-legs unarmed, and form no burrows, but deposit their eggs in the nests of other species. The true hornets (*Crabro*) excavate their retreat in wood, and feed their larvæ with the caterpillars of small moths found upon the oak, as well as with flies.

Cradling. In Architecture, the timber ribs in arched ceilings or cores to which the laths are nailed for the purpose of receiving the plastering are called *cradlings*, and generally any wood or iron substructure intended to receive an external coating is so called.

Craft. In Naval language, is a noun of multitude applied to any collection of decked vessels; but more commonly limited to small vessels.

Crag (Gael. *creag*, *a rock*). The name given to a part of the newer Tertiary formation in the east of England. It consists of a shelly sand and gravel used to fertilise soils where lime is wanting.

There is both a Norfolk crag and a Suffolk crag. The former is part of an accumulation of much newer date than the latter. It was

made at the bottom of the sea, but at or near the mouth of a river. It is rich in shells, probably derived from the older crag, and also contains bones of the inhabitants of the adjacent land, among whom the elephant must be ranked. The red crag and coralline crag, the former being the uppermost, were certainly accumulated farther from land and in deeper water than the Norfolk crag. They consist chiefly of shells and corals, passing into a soft building stone. The combined thickness is rarely more than fifty or sixty feet, but both deposits are wonderfully rich in organic remains of all kinds.

Crambe (Gr. and Lat. *cabbage*). *C. maritima* is the wild British plant, which yields Sea-kale under the hands of the gardener. It is a genus of the *Cruciferae* or cabbage tribe, found on our coast, and since its introduction to our gardens has furnished one of the most delicate of esculent vegetables, the parts used being the blanched leaf-stalks with more or less of the young stem, all in a succulent crisp condition.

Cramp. Spasmodic or involuntary contraction of some of the muscles, often attended with great pain; it is common in the muscles of the leg and foot, especially after any extraordinary exertion of them, and is sometimes brought on apparently by irritation in the stomach caused by indigestible food. When cramp seizes the calf of the leg, it usually goes off upon placing the limb in an erect posture and rubbing the affected part: persons subject to it find much relief by applying opiate liniments. If it arises from indigestion, or from indulgence in acescent drinks or champagne, mild bitters with magnesia, taken at bedtime, will generally prevent its recurrence.

CRAMP. In Architecture, this term is applied to a piece of metal dovetailed, or bent at each end, for the purpose of holding two blocks of any material firmly together.

Crame. In Mechanics, a machine for raising heavy weights, and depositing them at some distance from their original place; for example, raising bales from the hold of a ship, and depositing them on the quay. A jib or transverse beam, inclined to the vertical at an angle of 40° or 50°, is constructed, which, by means of a collar, turns on a vertical arbor. The upper end of the jib carries a fixed pulley, and the lower end a cylinder, which is put in motion by a wheel and pinion, or cog-wheel, or merely with a handle. The weight is made fast to a rope which passes over the pulley and is wound round the cylinder. On turning the cylinder, the weight is raised as far as necessary; the jib is then turned on its arbor till the weight is brought immediately over the spot where it is to be deposited; when, by withdrawing the moving power, it is allowed to descend by its own gravity. Cranes may be constructed of immense power. They are generally turned by human force; sometimes, however, by a steam-engine.

CRANE

CRANE. In Ornithology. [GRUS.]

Crangon (Gr. *κράγγων*). The name of the genus of Macrourous Crustaceans, including the common shrimp (*Crangon vulgaris*, Fabr.). This species abounds most on sandy coasts, and is caught by means of a large open net fixed to the end of a long stick.

Craniology. [PNEUROLOGY.]

Cranium (Lat.; Gr. *κράνιον*). Sometimes applied to the entire bony compages of the head of the vertebrate animals; but, in Human Anatomy, is restricted to that portion of the skull which surrounds the brain.

Crank. A rigid arm fixed at one extremity on a shaft perpendicular to its own axis, and receiving at the other an alternative impulse which causes it to revolve in a circle. It is the most usual mode of converting alternative circular or rectilinear motions into continuous circular motion, or vice versa; and for this purpose the crank requires to be connected with the prime mover by a chord or a rigid rod. In building operations, it is used to change the direction of the motion of bell-wires or other similar works.

CRANK (Ger. *krank*, *sick*). In Nautical language, a ship is said to be *crank*, when by the form of its construction, or by want of a sufficient quantity of ballast or cargo, or by being loaded too much above, it is incapable of carrying sail without being exposed to the danger of oversetting.

Grape (Fr. *crêpe*; Mr. Wedgwood connects the word with *criep*). A species of gauze made of raw silk woven without crossing.

Grape Ring. [SATURN.]

Crassulaceæ (Crassula, one of the genera).

A natural order of herbaceous or shrubby Exogens, of the Violal alliance, growing in hot, dry, and exposed situations. They are remarkable for the succulent nature of their stems and leaves, their many-leaved calyx, hypogynous petals, and their follicular apocarpous fruit. They have an affinity with *Saxifragaceæ* through *Penthorum*, and with *Illecebraceæ* through *Tillæa*; and possess refrigerant abstergent properties, mixed at times with a good deal of acidity.

Crater (Gr. *a mixing bowl*). The mouth of a VOLCANO [which see].

Crayons (Fr.). Coloured cylinders used for drawing upon paper; they are usually made of a fine pipe-clay, coloured with metallic pigments or carmine. Crayons containing plumbago are styled *solid lead pencils*.

Cream (Fr. *crème*). A semifluid yellowish substance which collects on the surface of milk, and which is made into butter by the process of churning. When the milk of any animal is allowed to stand for some time, it spontaneously undergoes certain changes; the cream rises to the surface, and forms a thin stratum, which consists chiefly of oily globules; while the milk below, which of course is thinner than it was before the cream separated from it, is of a pale bluish colour, and consists of a solution of the curd, or caseum, in the whey.

CREDENTIALS, LETTERS OF

When cream is kept for some days, it gradually becomes thicker and partially coagulated; and if put into a linen bag and suspended in a cool room, it will acquire the consistence of soft cheese; and this is one among other modes of making cream-cheese. When cream is churned, it is resolved into butter and buttermilk. In order to make butter, it is not always necessary that the cream should be separated from the milk; but whether separated or not, the process is facilitated by allowing the liquid to stand for some time, during which a part of the sugar contained in the serum, or whey, is changed into an acid, which shortens the process of churning by facilitating the separation of the butter from the milk. When either cream or milk is churned without having previously become slightly sour, the process is more tedious; and sometimes, from causes not easily accounted for by the dairymaid, it is unsuccessful, and the milk is said to be *brutched*. The true cause, however, is the want of acidity; because it has been found that the addition of a very small portion of vinegar will dissolve the charm, and cause the almost immediate appearance of butter. Cream, when separated from milk and kept till it has become acid, is frequently eaten with sugar, and is one of the most delicious preparations of the dairy. Costrophine cream, so called from a village of that name in the neighbourhood of Edinburgh, is made by putting the milk of three or four days together with the cream into a vessel, and allowing it to remain there till it has become sour and coagulated. The whey is then drawn off, and fresh cream added; and when it is brought to table it is eaten with sugar, and in the strawberry season with that fruit. Devonshire cream is simply sour curd, or sour cream, mixed with fresh milk, or fresh cream, and eaten with or without sugar. Devonshire scalded or clouted cream is milk and cream heated to the boiling point, and suffered to cool, when the cream will be found to have separated from the milk, and when skimmed off may either be made into butter or eaten with fresh cream and sugar. Common clotted cream is simply milk and cream in a coagulated state, and sour. When the clotted cream is broken and stirred, and the whey drawn off, the mass may be turned into cheese by artificial pressure, or by suspending it in a porous bag, in a cool airy situation. [BUTTER; CHEESE.]

Cressote. [KERASOTE.]

Creatine. [KERATINE.]

Credence Table. In Ecclesiastical Architecture, this term is applied to a table put near one side of the altar to receive the utensils required for the ministration of the Holy Communion.

Credentials, Letters of. The instrument in the form of a letter, from one monarch to another, which constitutes the evidence of the title of a minister at a foreign court to the power which he exercises. There are two sorts

CREDIT

of credentials: the one sealed, drawn up and countersigned by the minister of foreign affairs; the other open, signed only by the king. Unless the minister be mentioned expressly in his credentials as an ambassador, he has a right only to the observances due to foreign ministers of inferior rank.

Credit (from Lat. *credo, I give credit to*). In Political Economy, this term is used to express the lending of wealth, or of the means of acquiring wealth, by one individual or set of individuals to another. The party who lends is said to give credit, and the party who borrows to obtain credit. Hence credit may be defined to be the acquisition by one party of the wealth of another in loan, according to conditions voluntarily agreed on between them.

Very exaggerated notions are commonly entertained of the influences of credit; but, in fact, all operations in which credit is given or acquired resolve themselves into a new distribution of wealth already in existence. The *magical* effect that is every now and then ascribed to credit is due to the fact that by the confidence implied in the giving credit, capital heretofore dormant or imperfectly productive becomes active or productive. A party who purchases goods payable at some future date obviously acquires the command of so much of the capital of the seller of the goods as their value amounts to, in the same way that a party who discounts a bill acquires the command of a corresponding portion of the capital of the discounteer. Wealth is not created by the issue of bills; and all that their negotiation does is to transfer already existing property from one individual or party to another; or, to exhibit the fact in a still more simple form, the credit given by A to B is an asset of A and a liability of B. To confound credit with wealth, is to confound the economical organisation of society with society itself.

In the great majority of cases loans are made by individuals who wish to retire from business, or who have more capital than they can advantageously employ, to individuals entering into business, or who wish to extend their concerns and to acquire a greater command of capital. The probability is, that capital will be more likely to be efficiently employed by the latter than by the former class of persons; and the advantage of credit, in a national point of view, consists in that circumstance. Loans made to prodigals or spendthrifts, or to individuals who expend them on unprofitable undertakings, are, in so far, publicly injurious; but, speaking generally, these bear but a very small proportion to the other class of loans, or those made to individuals by whom they are advantageously expended.

Public credit is the phrase used to express the trust or confidence placed in the state by those who lend money to government.

The interest or premium paid by the borrowers to the lenders depends on a great variety

CRÉDIT MOBILIER

of circumstances—partly on the rate of profit that may be made by the employment of capital at the time, partly on the duration of the loan and the security for its repayment, and partly on the facilities given by the law for enforcing payment. The only way, indeed, in which a government can advantageously interfere to encourage credit is by simplifying the administration of the law, and by giving every facility for carrying the conditions of contracts into effect.

Crédit Foncier. This is an expedient by which, at different periods and places, sums needed for the improvement of estates have been raised for specified periods, the security being at once on the particular estate of the borrower and the joint guarantee of the subscribers to the association. Ordinarily, a sinking fund has been created simultaneously with the loan. Illustrations of this scheme may be found in our own country, in the powers given to boards of guardians and local commissioners of borrowing sums upon the security of rates; the sums to be repaid by instalments at definite periods, and to bear a fixed rate of interest during the term. The system has been extended in France, by giving powers to joint-stock companies to act as intermediaries in such transactions, the profits of the society being derived from a percentage charged for their superintendence and guarantee. In England these functions are generally performed by insurance companies, who, being able by the very circumstances of their existence to make loans for considerable periods on the stipulation of the gradual repayment of the principal, are enabled to fulfil some very important functions in operations of great public utility or necessity.

As long as the obligations created by these transactions are not transferable, except in the ordinary way of notice and registration, the effect of the *Crédit Foncier* is, on the general hypothesis of prudence in advances, of great public benefit. Sometimes, however, the securities created have been treated as susceptible of simple assignment or transfer without endorsement, and have thus been employed as a form of currency, and circulated as likely to be popular in consequence of the accruing interest implied in their possession. From such a theory it is but a short step to attempt a compulsory paper currency, based, or supposed to be based, on other commodities than gold and silver. It is almost needless to say that this theory always involves the most fatal consequences, and that experience from the time of Law's scheme onwards has always demonstrated the madness of attempting any circulation which is not based on the precious metals. (*Tooke's History of Prices*, vol. vi. pp. 96 sqq.)

Crédit Mobilier. This is a name given to a gigantic scheme promulgated in France in 1852, and sanctioned by the existing government, the objects of which are: 1. To take in hand and originate trading enterprises of all kinds on the principle of limited liability. 2. To supersede

CREDITOR

or buy up trading companies, e.g. railway companies, and to substitute scrip and shares of its own, and in its own name, for the shares and bonds of the company; and 3. To carry on, on the limited liability principle, the business as a bank or bankers and a stock jobber.

It will be manifest that schemes so vast as these contain in them elements of considerable commercial risk, and are singularly provocative of wild and injudicious speculation. The reader will find the plan severely criticised by Mr. Tooke (*History of Prices*); and certainly no words are too strong, if we look at such an association from the point of view taken by English practice, and by the light afforded by past experience, to stigmatise so rash and dangerous an accumulation of purposes. But it must be borne in mind that France, from the character of its political and social organisation, is at once singularly disposed to such expedients and very capable of accommodation to them. The people are familiar with government superintendence, and the undertakings in question are supplied, as a rule, by small contributions of capital. During the past year (1864), financial schemes analogous to those above named have been started in England, and at present have found favour with the public. But the circumstances of the period referred to have been so exceptional, and the high rate of interest has caused so great an activity in all departments of the money market, that, while we can very well account for the disposition to enter into schemes analogous to those described above, it would be wholly premature to venture any prediction as to their ultimate success. Of one thing we may be quite sure, that any plan which seems to create negotiable securities for long terms, or which bases its operations on obligations which are not readily convertible, is, judging by the past, unsafe and unwise, and wholly unlike in character all those undertakings which have hitherto been successful.

Creditor. [BANKRUPTCY.]

Creed. Any brief summary of Christian belief; but more especially either of the three confessions commonly called the Apostles', Nicene, and Athanasian. The term is derived from the Latin *credo*, *I believe*; in like manner as *Paternoster*, *Ave Maria*, &c., are prayers named from the first words of these formulas in the Latin tongue.

Creek (A.-Sax. *crecca*, Fr. *crique*). A shore or bank on which the water beats, running in a small channel from any part of the sea. It is also applied to any part of a large river which is resorted to as a harbour or landing place by small craft. In the United States, the term *creek* is used as synonymous with our English word *brook* or *rivulet*.

Creel. A kind of basket; as, for instance, the baskets used by anglers.

Cremation (Lat. *crematio*). In Antiquities, a word particularly used to designate the ancient practice of burning the dead.

Cremocarp (a word made up from Gr. *κρεμωρην*, *I suspend*, and *καρπός*, *fruit*). A

CRESCENT

two to five celled inferior fruit, the cells of which are one-seeded, indehiscent, dry, perfectly close at all times, and when ripe hanging separate from a common axis, as in umbelliferous plants.

Cremona. A general designation of the violins made at Cremona in Italy, during the seventeenth and eighteenth centuries, chiefly by the family Amati. [VIOLIN.] Cremona is also a name erroneously given to a stop in the organ; being nothing more than a corruption of *krumhorn*, an ancient wind instrument, which it was originally designed to imitate.

Crenel (Fr. *creneau*, *battement*). A word employed in Gothic military architecture to express the battlements of a castle, or other building, which are so broken as to provide shelter for a man with a bow and arrow, or some other weapon of offence. During the latter part of the middle ages, crenellated parapets were introduced into buildings of all kinds.

Creole Acid or **Xenon Acid** (Gr. *σφην*, *a fountain*). A term applied by Berzelius to a species of extractive matter occurring in spring-water.

Creole (Span. *criollo*). A name given to the descendants of whites born in Mexico, South America, and the West Indies; in whom the European blood has been mixed with that of other races. The various jargons spoken in the West India islands by slaves, &c., are called *Creole dialects*.

Creptus (Lat.). The crackling noise which is produced upon pressing cellular membrane when it contains air.

Crescendo (Ital.). In Music, a direction to the performer to increase the loudness of the sound; marked thus <.

Crescent (Lat. *cresco*, *I increase*). In Heraldry, a bearing in form of a young moon. When the horns are turned towards the chief or upper part of the shield, it is called *crescent*, in contradistinction to the terms *increscent* and *decreascent*; in the former of which the horns are turned to the right, and in the latter to the left side of the shield. The crescent is frequently used to distinguish the coat armour of a second brother or junior family from that of the principal branch. As is well known, the crescent, or, as it is usually designated, the *crescent montant*, has become the symbol of the Turkish Empire, which has thence been frequently styled the Empire of the Crescent. This symbol, however, did not originate with the Turks. Long before their conquest of Constantinople the crescent had been used as emblematic of sovereignty, as may be seen from the still existing medals struck in honour of Augustus, Trajan, and others, and it had always been the symbol of Byzantium. On the overthrow of this empire by Mohammed II., the Turks, regarding the crescent which everywhere met their eye as a good omen, adopted it as their chief bearing; and it has continued ever since to decorate their minarets, their insignia, their dress, and in

short everything appertaining to their empire. Crescent has also been applied to three orders of knighthood, the first of which was instituted by Charles I., king of Naples and Sicily, in 1268; the second by Rene of Anjou, in 1448; and the third by the Sultan Selim in 1801, two years after the battle of Aboukir. The last-mentioned order is still in existence, and is remarkable for the fact that none but Christians are eligible for admission.

Crescentiaceæ (Crescentia, one of the genera). An order of Bignonial Exogens, allied to *Bignoniaceæ*, but differing in their one-celled ovary with parietal placentæ, and in their large succulent fruit with almond-like wingless seeds. They form trees, and abound in the tropics of Asia, Africa, and America. *Crescentia Cyprip*, the Calabash-tree, grows thirty feet high, and the hard woody shell of its fruit serves for various domestic uses.

Crest (Lat. *crista*). In Architecture, a term applied to a running ornament in a horizontal direction above the line of the cornice, as on the ridge of a roof, a canopy, or any similar works.

Crest (Lat.). In Heraldry, the ornament affixed to the helmet, being a personal or hereditary device. Warriors bore insignia peculiar to themselves in this manner among the classical ancients. The earliest instance of the heraldic crest in England is said to be that of Edmund Crouchback, earl of Lancaster (about 1280). The crest is, in modern blazonry, a figure placed upon a wreath, coronet, or cap of maintenance, which surmounts the coat of arms. It is not unfrequently a repetition of some bearing in the shield itself; as, the crest of Castile is a castle.

Creteaceous System (Lat. *creta*, *chalk*). The newest of the secondary or mesozoic series of rocks, underlying the tertiaries and resting on the Wealden or oolitic rocks. It is subdivided in England into CHALK and GREENSAND, but elsewhere the representatives are very varied. Limestones represent the upper and sandstones the lower portion of the system, and the whole may be regarded as highly fossiliferous, though with many barren places. [CHALK; GAULT; UPPER GREENSAND and LOWER GREENSAND.]

Crétins. A name applied in the Valais and elsewhere to a class of idiots, who are also generally afflicted with Goitres [which see].

Crew of a Ship. Comprises all the officers and men, combatant and non-combatant. In a large vessel the word *crew* is also applied to several smaller sections of men, as the carpenter's crew, sailmaker's crew, &c., signifying respectively the carpenter and sailmaker with their several subordinates.

Crib (Dutch, *kribbe*; Ger. *krippe*). Sometimes applied to a rack for hay or straw for cattle, and sometimes to a manger for corn or chaff; also to a small enclosure in a cow-house or shed for calves or sheep.

Crib-biting. Biting the manger or crib; a bad habit among horses, brought on by un-

casiness occasioned by diseases of the teeth, or by roughness in the person who currycombs them.

Cribbage. A very popular game at cards for two persons. Five cards are dealt to each, when each player casts out two, to form what is called the *crib*, of four cards, which belongs to the dealer. The elder hand then cuts the pack, and the dealer turns up a card, which is called the *turn-up*, and is considered in scoring (as hereafter explained) to belong to both hands as well as to the crib. The parties then play out, alternately, the cards in their hands, beginning with the elder hand, and counting the pips (every court card counts ten) up to 31, beyond which the play is not carried. The game is 61 points, which are scored with pips on a board called a *cribbage-board*, having 61 holes on each side. Points are made as follows: (1.) Any combination of cards in hands or crib (including always the turn-up in both) the united pips of which make up 15, scores 2 points, and if the hand contain also a duplicate of any one card of the combination, the 15 is counted twice over. (2.) A sequence in rank (without reference to suit) of three or more cards scores 1 for each card, and is scored twice if there be also a duplicate of one of the cards. (3.) Two similar cards of different suits (as two fours, two kings, &c.), form a *pair*, and score 2. Three form a *pair-royal*, scoring 6, and four a *double pair-royal*, scoring 12. *Example*: Two sevens, an eight, and a nine, in crib, with an eight turned up, would score 24, i.e. 4 fiftens = 8, 4 sequences of 3 = 12, and 2 pairs = 4. (4.) If the three cards in either hand, or the five cards in crib and turn-up, are all of the same suit, it is called a *flush*, and scores one for each card. (5.) When the turn-up is a knave, the dealer scores 2; and if there be a knave of the same suit as the turn-up in either hand or the crib, the holder scores 1. (6.) In playing the hands, any fiftens, pairs, or sequences made by cards consecutively played score for the person who plays the last card of them. The last card of the play, if it counts 31, scores 2; if under 31, it scores 1. The elder hand at the beginning of the game scores 3. Cribbage is sometimes played with six cards, but this does not make so good a game.

Cribble. A coarse sieve, or screen, for sifting sand, gravel, or corn; the term is also applied to a sort of coarse meal.

Crichtonite. A variety of Titaniferous Iron, found in Dauphiné, and named after Dr. Crichton.

Cricket. A well-known game played with bat and ball. The word is perhaps derived from the Anglo-Saxon *creag*, a *crooked stick*; but, although the game itself seems to have been known in the thirteenth century, no reference is found to it under its present name till towards the close of the seventeenth. The south and south-eastern counties of England took up the game with the greatest ardour; and the parish of Farnham, in Surrey, was

especially celebrated for the skill of its players towards the end of the last century, when the game was slowly acquiring general popularity. More recently the taste for this manly game has been widely spread throughout England and the southern parts of Scotland, although it has not yet made itself popular in any other country. In both the games of cricket, called *double-wicket* and *single-wicket*, the victory is won by that side which obtains the greatest number of runs in two innings. The laws of the game were revised by the Marylebone Club in 1844.

CRICKET. In Entomology. [GRYLLUS.]

Cricoid (Gr. *κρικειδής*). Annular or ring-shaped. A cartilage of the larynx is hence called the *cricoid cartilage*.

Crime. [LAW, CRIMINAL.]

Cringles. On Shipboard, loops formed in the bolt-ropes of the sails by intertwisting the strands composing the ropes. The object is to enable the bolt-ropes to be gathered up by a rope passed through them.

Crino. A cuticular disease, supposed to arise from the insinuation of a *hair-worm* under the skin of infants.

Crinoideans, Crinoidea (Gr. *κρίνον*, a lily, and *εἶδος*, appearance). A name given by Müller to an extinct family of Echinoderms, having a radiated, lily-shaped disc, supported on a jointed stem. When this stem is cylindrical, the species are termed *ENCRINITES*; when it is pentagonal, *PANTACRINITES* [see those words].

Crisis (Gr. a judging). In Medicine, certain symptoms which announce a favourable or an unfavourable termination of a disease are called *critical symptoms*, and the period at which they show themselves the *crisis* of the disease. In the progress of fevers these symptoms have been supposed to show themselves at certain definite periods, which therefore have been called *critical days*.

Crithmum (Gr. *κριθή*, barley, from the resemblance of the fruits). An umbelliferous plant, found on our rocky coasts. It yields Samphire, which consists of the young leaves of *C. maritimum*, and is valued as a pickle.

Critical Philosophy. The metaphysical system of Kant is sometimes so termed, from his famous work, the *Kritik der Reinen Vernunft* (Critique of Pure Reason). [KANTIAN PHILOSOPHY.]

Criticism (Gr. *κριτικός*, from *κρίνω*, I judge). Has been defined 'the art of judging with propriety concerning any object, or combination of objects.' In a somewhat more limited, but still extensive meaning, its province is confined to literature, philology, and the fine arts; and to subjects of antiquarian, scientific, or historical investigation. In this sense, every branch of literary study, as well as each of the fine arts, has its proper criticism as an appendage to it. The elements of criticism depend on the two principles of Beauty and Truth, one of which is the final end or object of study in every one of its pursuits: Beauty, in letters and the arts;

Truth, in history and the sciences. The office of criticism, therefore, is, first to lay down those forms or essential ideas which answer to our conception of the beautiful or the true in each branch of study; and, next, to point out by reference to those ideas the excellences or defects of individual works, as they approach or diverge from the requisite standard in each particular. Thus, historical criticism teaches us to distinguish the true from the false, or the probable from the improbable, in historical works; scientific criticism has the same object in each respective line of science; while literary criticism, in a general sense, has for its principal employment the investigation of the merits and demerits of style or diction, according to the received standard of excellence in every language; and, in poetry and the arts, criticism develops the principles of that more refined and exquisite sense of beauty which forms the ideal model of perfection in each. [BELLES-LETTRES AND RHETORIC.]

Criticism, in a more limited sense, is a branch of belles-lettres. Essays written for the purpose of commending or censuring works in literature or the arts, and pointing out their various merits and defects, are works in the critical department. Thus the term *periodical criticism* is used to express the body of writing contained in the various works under the name of magazines, reviews, &c., which are periodically published in most literary countries.

Crocidolite (Gr. *κροκίς* or *κροκός*, a woof, and *λίθος*, stone). A hydrated silicate of protoxide of iron, soda and magnesia: found in South Africa in the Griqua country beyond the Great Orange River, and in the micaceous porphyry of Wakenbach in the Vosges.

Crochets. In Gothic Architecture, ornaments resembling curved and bent foliage running up on the edge of a gable or a pinnacle. They are of two varieties; the earliest are formed by simple curves turning downwards, as in the gables and spires of Lincoln Minster; the latter having the point of the leaves returned and pointing upwards. Sometimes animals are substituted in place of the leaves in the later examples, about the time of the Renaissance.

Crocodile (Gr. *κροκόδειλος*). A name first applied by Herodotus to the crocodile of Egypt, because that animal resembled a small lizard of the same name (*Stellio* of the moderns), which is now known in Greece under the name of *Kosloridylos*. The Egyptian and other species of crocodile were confounded by Linnæus under the name of *Lacerta Crocodilus*; but the crocodiles are distinguished from all Saurian reptiles, or *Lacertilia*, by the following characters: They have a long and powerful tail, which is flattened in the vertical direction, to serve as the principal means of propelling the body through water with the swiftness required in the pursuit of fish, which form the principal prey of the crocodile. The extremities are short, and comparatively of little use in aquatic

progression, except in guiding and changing the direction of the motion, for which purpose they are always webbed or half-webbed. The fleshy tongue is attached by its entire marginal circumference, as in most fishes, to the inner side of the lower jaw, and is not extensible, as is the case, in all true lizards. The teeth are simple, conical, sharp-pointed, large, lodged in distinct sockets, and arranged in a single row; which structure and disposition are in relation with the carnivorous habits of the crocodile. Lastly, the intromittent organ of the male is single.

To these essential differences between the crocodiles and lizards may be added the following characters, which are common to all the crocodiles:—

1. The fore-feet have five toes; the hind-feet four toes.

2. Three toes only on each foot are armed with claws; so that there are two toes in front and one behind which have no claws.

3. The whole of the tail and the upper and under parts of the body are covered with square scutes or plate-scales; and the greater number of those on the back are traversed longitudinally by a more or less prominent ridge.

4. The sides of the body are covered with small round scales.

5. The ridges on the scales of the tail form at its base two prominent lateral series, or dentated keel-like crests, which converge and blend into one at the posterior part of the tail.

6. The tympanum or drum of the ear is protected by two movable flaps.

7. The eyes are provided with three eyelids.

8. Two little pouches containing a substance of a musky odour.

Their anatomy also affords some characters which are common to all the species, and very well distinguish their skeleton from that of other Saurians. The ventricles of the heart do not intercommunicate. The vertebrae in the cervical region support a series of spurious ribs, which are directed backwards, and the extremities of each overlapping the next in succession prevent the animal from turning the head to the side. This structure, it will be seen, is in admirable accordance with the aquatic habits of these large piscivorous reptiles; since, in order to displace the fluid medium through which they move, it is essential that the head should be firmly locked to the trunk. It is for this reason that the vertebrae immediately behind the head in fishes bear ribs; and the cervical vertebrae of the whale, although they accord in their number and in the absence of ribs with those of other mammals, are modified so as to answer the same end as the costo-cervical vertebrae of crocodiles and fishes, being compressed from before backwards, and ankylosed sometimes into a single piece.

Croconic Acid (Gr. *κρόκος*, saffron). A yellow substance resulting from the action of potassium on carbonic oxide. It is not easily soluble, and has a sour astringent taste.

Crocus (Lat.; Gr. *κρόκος*). A familiar genus of *Iridaceae*, yielding some of our most beautiful spring flowers, and furnishing also the Saffron of commerce, which consists of the deep orange-coloured stigmas of *C. sativus* gathered with part of the style, and carefully dried.

Croft (A.-Sax.). A small field adjoining the dwelling-house and kitchen garden. The term is also sometimes applied to common field lands. An *undercroft* sometimes signifies a crypt.

Cromfordite or **Horn Lead**. Chloro-carbonate of lead. This rare mineral was originally obtained from a mine near Cromford in Derbyshire; but it has, also, been met with in Cornwall, at Elgin in Scotland, and on the volcanic sand of Vesuvius.

Cromlechs. In British Antiquities, the term *cromlech* is applied to large flat stones laid across others fixed vertically in the ground, which are found in parts of Wales, in Devonshire, Cornwall, and some other districts in England; in Brittany, Denmark, Germany, and some other parts of Europe. Cromlechs have usually been supposed to have served as altars, but their first purpose was to serve as places of burial. (Worsae, *Scandinavian Antiquities*.)

Cronstedite. A hydrated silicate of iron, named after Cronstedt, the Swedish mineralogist.

Crops, Rotation of. [AGRICULTURE.]

Croquet. A game recently introduced into this country, and played with balls and clubs, the object of the game being to propel a ball, a number of hoops fastened into the ground, to a fixed goal, and thence back to the starting point. The laws of the game have been explained in a treatise by M. Jaques.

Crosier. The staff of an archbishop, surmounted by a cross (whence its name), and thereby distinguished from the pastoral staff or crook of a bishop.

Cross (Lat. *crux*). A gibbet made of two pieces of wood laid upon each other at any angle. Originally, it was nothing more than a tree; but it afterwards assumed a variety of forms, of which the following are the most usual examples: × † ‡. The cross was used as a very general instrument of punishment from the earliest times. Among the Syrians, Jews, Egyptians, Persians, and especially the Carthaginians, it appears to have been the usual military punishment. (Val. Max. ii. 7; Herod. iii. 125-159.) But in no part of the ancient world was this punishment so generally resorted to as in the Roman empire, where it was regarded as the most infamous of deaths, and, except in cases of sedition, was inflicted only on slaves or the vilest malefactors. By the Roman law, the culprit was scourged previously to the crucifixion, either in the prætorium or on the way to the place of execution. On his arrival there he was stripped of his garments, and then either nailed by the hands and feet to the cross, or, as sometimes happened, only fastened to it by ropes. In order to hasten death, it was the practice to

CROSS

break the legs or to pierce the body of the sufferer with a spear or other sharp instrument; but this was not always done; and instances have occurred of persons who, after being suspended for some considerable time on the cross, were taken down and survived. By the Jewish law, it was ordained, that the body of the culprit should be removed from the cross on the day of his execution; but the Romans frequently allowed it to hang till it dropped piecemeal to the ground. In general, the cross was erected near some great road or highway, in order to indicate more distinctly the ignominy of the culprit and the severity of his death.

By the death of Christ, the cross, from being an object of horror, became the symbol of the Christian world, and in the end came to be regarded even with superstitious veneration. Constantine, from respect for these feelings, abolished the punishment of crucifixion throughout the Roman world.

In the Romish church certain festivals are observed in memory of circumstances connected with the cross; as the Invention or Discovery and the Exaltation of the Cross: the former commemorates the supposed discovery of the true cross by the Empress Helena, the latter its restoration to Calvary by Heraclius.

CROSS, GREEK AND LATIN. The cross on which our Lord suffered is commonly considered to have been the *crux capitata* with the lower limb longer than the others, †. But the cross with equal limbs, commonly termed the *Greek cross*, has been the model followed in the architecture of Eastern churches, and would have been followed in St. Peter's at Rome had the original plan of Michael Angelo been executed.

CROSS. In Heraldry, an ordinary, formed by lines drawn palewise and fesswise, enclosing (if bounded by the escutcheon) one-fifth of the shield, or one-third if charged. A cross gules is termed the *cross of St. George*. A plain cross is one of which the extremities do not reach to the circumference of the escutcheon, but are *couped*, or cut off in a straight line. There are many other kinds of crosses, not reaching the circumference of the escutcheon, known in heraldry; the following are only a few, most commonly used in bearings: A *cross crosslet* is one crossed on each arm. Such a cross between four plain crosses is termed a *Jerusalem cross*. A *cross fretty* has three points at each end. A *Maltese cross* has arms increasing in breadth towards the end, with double points. A *cross sickle* has the lower limb pointed, as if to fix in the ground. A *patriarchal cross*, the insignia of patriarchs or archbishops, is plain; having two bars, the upper smaller than the lower. A *cross moline* terminates in representations of the ends of the fer-de-moulin, or millrind. It is the difference of the eighth son of a family.

CROSS. An instrument formerly used in surveying for laying out perpendicular lines, but now seldom employed. It consists of a brass cross or circle, divided into four equal

CROSSETTES

parts by two diameters at right angles to each other. At each extremity of these diameters perpendicular sights are fixed. The instrument is mounted on a staff to fix it in the ground, and its use is to find, in a given line, the foot of the perpendicular let fall thereon from an object at some distance.

CROSSES, STONE. In Architectural Antiquities, are of various kinds, according to the occasion or purpose of their erection. They are said to have originated in the practice of marking the Druidical stones with a cross at the period of the conversion of the Celtic tribes to Christianity. *Preaching crosses* are generally quadrangular or hexagonal, open on one or both sides, and raised on steps; they were used for the delivery of sermons in the open air: the celebrated Paul's Cross was an instance of this application. *Market crosses* are well known, from the examples of Winchester, Chichester, Aberdeen, Malmesbury, &c. *Weeping crosses* were so called because penances were finished before them. *Crosses of memorial* were raised on various occasions; sometimes where the bier of an eminent person had stopped on its way to the place of burial, sometimes in attestation of a miracle performed on the spot: the crosses erected at the resting-places of Queen Philippa's bier may be cited as illustrations of this variety. Crosses served also as landmarks; they were originally used for this purpose by the Templars and Hospitallars of St. John of Jerusalem.

Cross Flookana. A name applied by the miners of Cornwall to veins of stony matter running north and south.

Cross Jack Ward. In Navigation, the lower yard in the mizen-mast.

Cross-bow. A weapon used for shooting with, before the invention of firearms. All weapons having the bow attached to a stock were called cross-bows; and some of the larger sort were furnished with instruments for bending the bow. [ARRALEST.]

Cross-breed. The offspring of parents of two different breeds.

Cross-furrow. A furrow or open trench cut across other furrows to intercept the water which runs along them, in order to convey it to the margin of the field, where it may find its way to an open ditch or some other general drain.

Cross-stone. A mineralogical synonym for Staurolite. The name has also been applied to Harmotome in consequence of the intersection of the crystals, which often cross each other at right angles and lengthwise, so that their axes coincide. [ANDERSSON, GOLITZ and HARMOTOME.]

Crossettes (Fr.). In Architecture, the returns on the corners of door cases or window frames; called also *cars, elbows, ancones, prothyrides*. In architectural construction, they are the small projecting pieces in arch stones which hang upon the adjacent stones—*a, a, a, a*.

CROTALARIA

Crotalaria (Gr. *κρόταλον*, a rattle). A very extensive genus of tropical herbs or shrubs of the order *Leguminosae*, the most important of which is *C. juncea*, the Sunn Hemp of India, a plant extensively cultivated for its fibre, which is considered equal if not superior to Russian hemp.

Crotalum (Gr. *κρόταλον*). An ancient kind of castanet, used by the Corybantes or priests of Cybele. This instrument must not be confounded with the modern *crotalo*, a musical instrument used chiefly by the Turks, and corresponding exactly with the ancient cymbalum.

Crotalus (Gr. *κρόταλον*). A genus poisonous serpents, including those which are furnished with a rattle at the extremity of the tail.

Crotchet. In Music, one of the notes or characters of time, equal to half a minim.

Crotchets. In Grammar, more frequently called *brackets*, are certain marks or hooks in which words or phrases are included thus [], by way of distinguishing them from or illustrating the context.

Croton (Gr.). An important genus of *Euphorbiaceae*, consisting of herbs or trees with monocious flowers having a five-parted calyx, the five-petaled males with ten stamens, and the apetalous females with three styles. *C. Tiglium* is a medicinal Indian species, the purgative seeds of which yield an acrid oil. *C. Elaeuthera* of the West Indies is the source of the aromatic Cascarrilla bark. *C. lacciferum* in Ceylon and *C. Draco* in Mexico furnish resins used in making varnish.

Croton Oil. The expressed oil of the seeds of the *Croton Tiglium*; formerly called *Grana Tiglia*, and *Molucca grains*. The tree is a native of Ceylon, and of Malabar and the Molucca Islands. Its seeds are very purgative; and their expressed oil so drastic, that a single drop will often prove violently operative, completely emptying the bowels and exciting a copious watery secretion from them. The most active form for its exhibition is made into a pill with bread crumb: it may also be rubbed with a little mucilage of gum arabic, and given in a liquid form; but it always requires much caution in its administration.

Croup. An inflammation of the larynx and trachea, accompanied by difficulty of breathing and cough, and by a peculiar shrillness of voice and wheezing; there is also generally more or less expectoration of purulent and filmy matter, which is thrown out upon the affected part and continually threatens suffocation. This disease is most common in infants, and in children from three to nine years old; it is of rare occurrence, in its acute form at least, after twelve years of age. In the successful treatment of this distressing and dangerous disease, everything depends upon promptitude in the application of remedies calculated to subdue the local inflammatory action. This is to be done either by leeches to the region of the trachea, by cupping, or by bleeding in the

CROWN

jugular vein; by the cautious application of external irritants of rapid action, such as a piece of lint dipped in strong acetic acid, which, however painful, is sometimes of service; by blisters, and by the exhibition of large doses of calomel: there is a difference of opinion as to the employment of emetics. The inhalation of steam is useful where it can be resorted to, but in young children it is impracticable. In *spasmodic croup* the wheezing and sense of suffocation appear to depend upon spasmodic action of the larynx or epiglottis: like the former, it attacks infants and children, but comes on and goes off very suddenly, returning at intervals, during which the patient is comparatively easy. In weakly and irritable children it sometimes appears to be a consequence of teething. An emetic, calomel purges, warm bath, diaphoretics, and a blister, are the leading remedies; bleeding should be avoided. There is a kind of croup which sometimes attacks children of weakly constitutions, and which appears symptomatic of irritation in the stomach and bowels, for it is relieved by purging, and disappears as the constitution improves. Another form of this disease is called *chronic croup*. It is attended by cough and the expectoration of tough mucus, sometimes apparently membranous or tubular, occasioning difficulty of breathing and suffocation. This disordered state of the trachea and bronchial membranes may occur at all periods of life: it is relieved, and often cured, by using the inhaler with warm water, by expectorants with small doses of sedatives and mercurials, and by occasional purging.

Crow Coal. A kind of coal almost without bitumen, which is found at Alston Moor in Cumberland.

Crow's Feet. Iron-pointed stars, or nails so radiating, that however thrown on the ground, they will always have a point uppermost. They are used as obstacles to the approach of an enemy, and are especially useful against cavalry.

Crown (Lat. *corona*). In Architecture, the uppermost member of a cornice; called also the *corona* or the *larmier*.

Crowns. In Heraldry. Among the ancients, and especially in the Roman republic, crowns were presented to citizens as marks of distinction for valiant or otherwise meritorious exploits. From this usage the crown has been adopted as a bearing by modern heralds. Nine species of the crown are enumerated in heraldry; some of which, however, have not been introduced into modern arms, and are only known from the description left of them by the ancients: 1. The Eastern Crown, imitated from that which appears on coins of reek oriental sovereigns, and borne by those who have distinguished themselves in the East: the East India Company's arms have this crown. 2. The Triumphal Crown, which, after being borne by Julius Cæsar, became the crown Imperial. 3. The plain Circlet or tiadem. 4. The Obsequial Crown, given

CROWN GLASS

among the Romans to those who had performed exploits in the defence of fortified places. 5. The Civic Crown, for saving the life of a citizen. 6. The Crown Vallery, to soldiers who had first entered the enemy's trench. 7. The Mural Crown, to soldiers distinguished in besieging armies. 8. The Naval Crown, common in English coats of augmentation. 9. The Crown Celestial.

Crown Glass. The glass usually employed for windows. It differs from *flint glass* in containing no oxide of lead, and is made of a mixture of 100 parts of sand, 35 of soda-ash or potash, and 35 of chalk. It is, therefore, essentially a silicate of soda, or potash, and lime. [GLASS.]

Crown or Demesne Lands (Low Lat. *Terra Dominicales*). The lands, estates, or other real property belonging to the crown or sovereign. These were anciently very extensive. The rents and other payments arising from them formed in the middle ages an important part of the revenue of our English kings; and they still form an important part of the revenue of several Continental sovereigns. These lands have been acquired by various means, such as purchase, succession, forfeiture, &c. Having been regarded for a lengthened period as the private property of the crown, and as being consequently at the free disposal of the sovereign for the time being, little providence has been displayed in their management. A grant of crown lands was, indeed, the ordinary method in which our sovereigns used formerly to gratify their favourites; and, in consequence of the magnitude and improvidence of such grants, the crown estates in this country have been reduced within very narrow limits. Parliament frequently interposed to check this profusion, but without effect till after the Revolution, when the lavish grants of crown lands, made by William III. to the Bentinck and other families, occasioned so much dissatisfaction that the practice was put an end to. This was done by the Act 1 Anne st. 1, cap. 7, which declared that all future grants or leases of land from the crown for a longer term than thirty-one years, and of houses for a longer term than fifty years, should be void.

The crown estates, forests, manorial rights, &c., not granted away, have now become, in consequence of arrangements to that effect, the property of the public; and are administered by a department specially appropriated to that purpose, called that of the 'Commissioners of Woods and Forests.' Their total nett revenue in 1863 amounted to about 432,000*l.*, the expenditure being 157,000*l.* Of late years a considerable extent of crown lands, consisting of old forests and chaces, has been enclosed and planted with forest trees, with a view to the supply of timber for the navy.

Croceophora. A genus of *Euphorbiaceæ* yielding the dye called *Turnsole*, which is obtained by grinding *C. tinctoria* to a pulp; this yields half its weight of dark green juice, be-

CRUSADES

coming purple by exposure. The herb grows wild in the countries bordering the Mediterranean, and is cultivated in the South of France.

Crucible (Lat. *crucio*, *I torment*; because, in the language of old chemistry, the metals were tortured by fire to yield up their various virtues). A vessel, generally made of very refractory earthenware, in constant use in the chemical laboratory for performing fusions of metals and other substances.

Cruciferae (Lat. *cross-bearers*; the flowers being in the form of a Maltese cross). A natural order of Cistal Exogens, inhabiting most of the temperate countries. They are allied to *Capparidacæ*, but differ in their tetradynamous stamens; and also to *Papaneracæ* and *Fumariacæ*, from which they are distinguished by their seeds, and by having no albumen. They are characterised essentially by their deviation from the ordinary symmetry observable in the relative arrangement of the parts of fructification of other plants. Linnaeus divided this order into *Siliquosæ* and *Siliculosæ*, from the forms of their fruits; but more recent divisions have been founded upon the nature of the plicature of the cotyledons, and the position of the radicle with respect to them. They all possess antiscorbutic and stimulant properties, combined with an acrid flavour; and their seeds abound in a fixed oil—properties, of which Cress, Mustard, Cabbage, and Rape may be taken as representatives.

Crucifix (Lat. *crucifixus*, *crucified*). The figure of Christ upon a cross; also a cross with the figure of Christ upon it.

Crude (Lat. *crudus*, *raw*). In Painting, a term applied to a picture where the colours are rudely laid on, and do not blend or harmonise with one another.

Cruise (Fr. *croiser*, Dutch *kruisen*, *to cross*). A voyage within certain limits for the purpose of meeting with enemy's ships, pirates, &c., or for mere exercise.

Cruires. This name is given to a trap for catching salmon; it consists of stone walls built across a river with an intermediate chamber of wooden spars, which the salmon may enter, but from which they cannot escape.

Crur (Lat.). In Anatomy, the red substance contained in the discs or corpuscles of the blood.

Crupper (Fr. *croupière*). A roll of leather put under a horse's tail, and connected with the saddle by a strap and buckle, for the purpose of preventing the saddle from being cast forward on the horse's neck by the action of riding.

Crura (Lat.). In Anatomy, are the bundles of nervous fibres which expand into the hemispheres of the cerebrum (*crura cerebri*) or of the cerebellum (*crura cerebelli*).

Crusades (Fr. *croisade*, from Lat. *crux*, *cross*). In the European History of the middle ages, wars undertaken by confederacies of chiefs and soldiers with a religious object. Those which were engaged in by great part of the nations of Europe for the recovery of

CRUSOA, ACCADEMIA DELLA

Palestine from the infidels are more frequently denoted by this peculiar name. The term *crusade* is derived from the sacred symbol of the cross, which was borne by the warriors engaged in it over their arms: the colour of the cross often served to designate the nation of the soldier; as the white cross on a red ground, France; the red cross on a white ground, England. The principal crusades for the conquest of Palestine were: 1. The first, A. D. 1096, excited by the preaching of Peter the Hermit and the encouragement of Pope Urban II., in which Godfrey of Boulogne headed the Christians, who made themselves masters of Jerusalem and great part of Palestine. 2. The second, A. D. 1142, in which Conrad III. of Germany and Louis VII. of France led armies to complete the conquest of Palestine, but without success. 3. The third, A. D. 1189, was occasioned by the capture of Jerusalem by Sultan Saladin; Frederick (Barbarossa) of Germany, Philip Augustus of France, and Richard Cœur de Lion of England were the chief among the confederate monarchs: the capture of Acre was almost the only fruit of this great expedition. 4. The fourth crusade was conducted by the king of Hungary, Andrew II., in 1217. 5. The fifth was conducted by Frederick II. (the grandson of Barbarossa), who recovered Jerusalem, but for a short time. 6. The sixth, A. D. 1248, by Saint Louis, king of France, against Egypt, but without success. Among other wars which have been at various times denoted by the name of *crusades*, that against Raymond, count of Toulouse, and his heretical vassals, the Albigeois, of which the first leader was the famous Simon de Montfort, is the most memorable. [ALBIGENSES.] Whether the Crusades exercised a beneficial influence on the state and condition of society, is a question which has long engaged the attention of the learned, and on which the reader may consult with advantage the elaborate work of Michaud, *L'Histoire des Croisades*, and his *Bibliographie des Croisades*; Wilken's *Geschichte der Kreuzzüge*; Haken's *Gemälde der Kreuzzüge*; the art. 'Croisades' in the *Encyclopédie des Gens du Monde*; Milman's *Latin Christianity*, book vii. ch. vi.; Hallam's *Middle Ages*, ch. i. part i. &c.

Crusoa, Accademia della. [ACADEMY.]

Crust of the Earth. The name given by geologists to the whole series of stratified rocks coming under human observation. There being no means whatever of knowing the real condition of the earth's interior, it is convenient in speaking of what is positively known to distinguish between theory and observation. The total thickness of the earth's crust penetrated by man is not more than 2,000 feet below the sea, and the highest mountains are less than 30,000 feet above the sea. The actual total thickness of strata at any one point has never been estimated with any approach to accuracy, and is probably greatly overstated in books. It amounts at the most to a very few miles.

CRYPTOBRANCHUS

Crusta (Lat.). In Gem Sculpture, a gem engraved for inlaying on a vase or other object. **Crustaceans, Crustacea** (Lat. *crusta*, a hard covering). A class of free articulate animals, with articulated limbs, a branchial respiration, and a dorsal ventricle or heart. They are classified as follows:—

Subclass: Entomostraca.

Order: Trilobites.

Xiphosura.

Phyllopoda.

Cladocera.

Ostracoda.

Copepoda.

Subclass: Malacostraca.

Division: Edriophthalma.

Order: Læmmodipoda.

Isopoda.

Amphipoda.

Division: Podophthalma.

Order: Stomapoda.

Decapoda.

Tribes: Macroura.

Anomoura.

Brachyura.

Gryolite (Gr. *κρύος*, ice, and *λίθος*, stone; because it melts in the flame of a candle). A rare mineral found only in West Greenland, where it forms a mass 300 feet long and 80 feet thick. It is a double fluoride of aluminum and sodium. It has become an article of commerce as a source of aluminum.

Gryophorus (Gr. *κρύος*, and *φέρω*, I bear). The frost-bearer or carrier of cold; an instrument contrived by Dr. Wollaston for freezing water by its own evaporation. (*Phil. Trans.* 1813, p. 71.)

Crypt (Gr. *κρυπτός*, hidden). In Architecture, the under or hidden part of a building. The crypt at Canterbury Cathedral is one of the most perfect specimens of this kind of building extant in England.

Crypta. In Botany, the round receptacles for secretion present in the leaves of some plants, as in the orange and myrtle.

Cryptes. Little rounded excrescences, in which the minute ramifications of the arteries terminate in the cortical part of the kidneys.

Crypteia (Gr. *κρυπτεία*, a secret commission). A Spartan institution, attributed to Lycurgus, for the annual secret assassination of the Helots by young citizens sent out for the purpose. For this statement, the authority of Aristotle has been alleged (*Plutarch, Lyourg.* 28); but it is significant that he does not mention it in his treatise on Politics. Yet the existence of a system of espionage, carried on probably by the employment of young Spartans, admits of little doubt. (*Grote, History of Greece*, part ii. ch. vi.)

Crypte-porticus (Lat.). In Ancient Architecture, a concealed portico; also one which, for the sake of coolness, was enclosed on every side. Some of these buildings were sunk a considerable depth in the ground.

Cryptobranchus (Gr. *κρυπτός*, hidden, and *βράχυν*, gills). A genus of Batrachia, in which

CRYPTOGAMS

the gill-aperture disappears early in life. Three species are known, the *Cryptobranchus* (*Melopoma*) *alleganiensis*, found in many rivers of North America; the *C. fuscus*, from South Carolina; and the *C. japonicus*, which is the largest of all the known naked Amphibia, being three feet long. A fossil species is found in the tertiary strata at Eningen, which Schreber thought to be the bones of a man who had witnessed the deluge (*Homo diluvii testis, et theoscopos*). Cuvier demonstrated this animal to be merely a Salamander, and Van der Hoeven has named it *Cryptobranchus primigenius*.

Cryptogams (Gr. κρυπτός, *concealed*, and γάμος, *marriage*). The distinctive name of the various groups of flowerless plants, in opposition to the name given to those which bear flowers. [PNEUMOGAMS.] The name, implying hidden marriage, was given on the assumption that they really did possess sexual organs, though they had not been discovered; but the notion for a long time prevailed that these were absolutely wanting, and it was thought that the presence or absence of sexes was the chief distinction between flowering and flowerless plants.

The great distinctive point of Cryptogams does not, however, consist in the absence of decided male and female organs, nor in their minuteness, for in the greater part their presence has now been ascertained beyond all doubt. The main point, as Mr. Berkeley has well expressed it, is that the reproductive organs are not true seeds containing an embryo, but mere cells consisting of one or two membranes enclosing a granular matter. These bodies, whether called spores or sporidia, produce by germination a thread or mass of threads, a membrane, a cellular body, &c., as the case may be, which either at once gives rise to the fruit or to a plant producing fruit. Indeed, the differences are so great that these spores seem rather to be relatives, or what is technically termed *homologues*, of pollen grains, than of true seeds. The consideration of the relations between the reproductive organs of phanogams and cryptogams is one of the most interesting which is to be found in botany, but it is also one of the most abstruse and difficult.

Cryptogams are divided into two principal groups, namely:—

THALLOGENS, those which have the stems and leaves undistinguishable.

ACROGENS, those in which the stems and leaves are distinguishable.

The former of these groups contains the Fungi, Lichens, Seaweeds, and Characeae; the latter, the Equisetaceae, Hepaticae, Mosses, Club-mosses, and Ferns.

Cryptogamic plants are connected with Gymnosperms through *Lyco podiaceae* and *Equisetaceae*, with Rhizanthae through Fungi, and perhaps with Endogens through tree ferns; they do not appear to have any immediate relation to Exogens.

Cryptograpy (a word formed from the Gr. κρυπτός, *hidden*, and γράφω, *I write*). Also termed *Polygraphy* and *Steganography*. The

CRYSTALLISATION

art of writing in a manner intelligible only to those admitted into the secret of the method, either by conventional signs (cipher), or by other contrivances.

Cryptoline (Gr. κρυπτός). A fluid discovered by Sir David Brewster in minute cavities of Topaz, Chrysoberyl, Rock-Crystals from Quebec, and Siberian Amethyst.

Cryptolite (Gr. κρυπτός, and λίθος, *stone*). Native phosphate of cerium in which the cerium is partly replaced by didymium. It occurs in small yellow prisms, at Arendal in Norway, embedded in rose-coloured Apatite.

Cryptomorphite (Gr. κρυπτός, and μορφή, *form*). A species of hydrated borate of lime and soda, found near Windsor in Nova Scotia.

Crystal (Gr. κρυσταλλος, *ice*). This term was originally applied to those beautiful transparent varieties of silica, or quartz, known under the name of *rock crystal*. When substances pass from the fluid to the solid state, they frequently assume those regular forms which are generally termed *crystals*. [CRYSTALLISATION.]

Crystalline. [ANILINE.]

Crystalline Lens. The *lens* of the eye, placed in a depression upon the anterior part of the vitreous humour. [EYE.]

Crystalline Rocks. This name is given, in Geology, to such rocks as granite, quartzite, marble and others, which show by their crystalline structure that they have been brought into their present state owing to the action of chemical forces. In the early history of geology, such rocks were called *primitive*, but they are certainly not limited to any geological age, examples being found in the newest as well as the oldest. Even granite is comparatively modern, and there is no reason why crystalline rocks should not be at the present time in course of formation.

Crystallisation, Crystallography (Gr. κρυσταλλος, *a crystal*, and γράφω, *I describe*). The doctrine of the relation of crystalline forms, and of the origin and structure of crystals. Natural as well as artificial crystals occur in an infinite variety of forms; but they may generally be referred to some primary figure, of which these varieties may be regarded as modifications. The structure of crystallised bodies is most easily illustrated by reference to natural crystals, but the theory applies to all crystallised bodies; it assumes the existence of some definite primary figure, which by various truncations may be modified into its secondary forms.

The varieties of calcareous spar may be referred to as presenting one of the easiest illustrations of the mechanical texture of crystals, and of the modifications of which a definite primary figure is susceptible. Calcareous spar occurs in more than a hundred different forms, all of which, by careful mechanical division, are reducible to an *obtus rhomboid*, whose faces are inclined to each other at angles of 105° 8'; this, therefore, is called the *primary form* of calcareous spar.

The *secondary forms* are presumed to be derived from the primary forms in consequence

CRYSTALLISATION

of decrements of particles taking place upon the edges, or angles, or both, of the primary form. Thus, if the primary form were a cube, it might be reduced to a secondary octahedron by decrements, or *truncations*, in the direction of the planes produced by the removal of its solid angles; and by a similar operation a primary octahedron might become a secondary cube.

The doctrine of the relations and conversions of these forms is, properly speaking, a branch of solid geometry; but its practical applications to chemistry have in fact rendered crystallography a subsidiary branch of that science. By a careful examination of the forms and modifications, the texture and fracture of crystals, the chemist and mineralogist are in many cases enabled to determine their nature or composition; and in some cases a strict examination of such forms may supersede analysis, or other more circuitous methods.

When we attempt by cautious mechanical means to dissect a crystal, we find that it will only yield kindly and afford smooth surfaces when broken or divided in certain directions. A cube of fluor spar, for instance, will only give way under such circumstances in the direction of its solid angles or corners; if we pursue the division in such directions, an octahedron will be the resulting figure; and each side which is removed may be further divided into octahedra and tetrahedra. The new and smooth surfaces resulting from this division or *cleavage* of the crystal are called its *cleavage planes*; the line produced by the meeting of two planes is called the *edge* of the crystal; and the meeting of any two lines or edges forms a *plane angle*. A *solid angle* is produced by the meeting of three or more plane angles. Different crystallographers have assumed various primitive forms as the bases of their respective systems of crystallisation. Haüy assumed six (*Traité de Minéralogie*); Mr. Brooke enumerates fifteen primary forms (*Familiar Introduction to Crystallography*); and almost each author upon this subject has adopted different views as regards the number of fundamental forms and the modes of derivation of secondary figures. In Germany the system of crystallography of Mohs is pretty generally adopted. (Haidinger's translation of Mohs' *Mineralogy*.) But any detailed account of these different systems and theories would be inconsistent with our present object. It may be observed, however, that the theory of crystallisation is greatly simplified by assuming all secondary forms as resulting from the aggregation of primary spherical or spheroidal molecules. (See a paper on this subject by Dr. Wollaston, in the *Philosophical Transactions* for 1813; and Mr. Daniell's confirmations of the hypothesis in the first volume of the *Quarterly Journal of Science and the Arts*.)

The process of crystallisation is resorted to for many useful and important purposes in the arts: it is the principal means by which various saline products are obtained in a state of purity; for, in the act of crystallisation,

CUBE

they throw off foreign substances and acquire definite composition. It is thus, for instance, that nitre is purified for the manufacture of gunpowder, and that the common and other salts with which crude nitre is contaminated are got rid of; a crystal of nitre being of necessity a definite compound of 54 parts of nitric acid combined with 48 of potassa.

Nitre furnishes an instance of what is termed an *anhydrous* crystal; it retains none of the water in which it had been dissolved, and from which it is deposited. There are, however, many salts, the crystals of which are *hydropic*; and in such cases the quantity of water which they contain always bears a certain definite quantitative relation to the elements of the salts. Sulphate of magnesia, for instance, or Epsom salt, forms prismatic crystals, which always contain 51.2 per cent. of water of crystallisation: they are constituted of 20 parts of magnesia, 40 of sulphuric acid, and 63 of water.

The details of the various crystallographical systems which have been proposed, could only be made intelligible by woodcuts and diagrams, so numerous as to be inconsistent with the object of this work. The reader is therefore referred, for these details, to the articles on 'Crystallography' in the *Encyclopædia Britannica* and in Watts' *Chemical Dictionary*.

Crystalloids. [COLLOIDS.]

Ctenobranchiata (Gr. *κτείρ*, a comb, and *βράχτις*, gills). A name substituted by some naturalists for *Pectinibranchiata*; applied by Cuvier to that order of Gastropods which breathe by means of pectinated gills.

Ctenoides (Gr. *κτενοειδής*, like a comb). A name given by Agassiz to one of his orders of fishes, characterised by scales composed of layers with pectinated or toothed posterior margins. These combs overlapping one another give a rough feel to the skin; the scales are horny or bony, without enamel. The Ctenoid order includes the following families: *Chirodontes*, *Pleuronectes*, *Percoides*, *Polyacanthes*, *Scienoides*, *Sparoides*, *Scorpenoides*, *Aulostomes*.

Cubature. The measurement of the volume of a solid body. If the equation to the surface enclosing the body be given in rectangular coordinates, its volume is expressed by the triple integral $\iiint dx dy dz$, where the integration is to be extended to all points of the solid according to the methods explained in all text-books. When the equation to the surface is given in polar coordinates, its volume is expressed by the integral $\iiint r^2 \sin \theta dr d\theta d\phi$.

Cube (Gr. *κύβος*, a die). In Geometry, a solid body contained by six equal squares. It is also called a *regular hexahedron*. If a be the number of units of length in any side, then the volume of the cube will be $a.a.a=a^3$ times that of the cube whose sides are equal to the linear unit; or if the latter volume be taken as the unit of measure (*cubic unit*), then a^3 will express the volume of the first cube. Thus in Algebra and Arithmetic the third power of a number, or the product of three numbers equal to it, is called the *cube* of that number.

CUBE ORE

Cube Ore. A hydrated arseniate of iron, crystallising in cubes.

Cube Root. In Arithmetic, the number whose cube is equal to a given number. In Algebra, the *three* cube roots of any quantity are the three quantities, real or imaginary, each of which, when cubed, reproduces the original quantity. The *three* cube roots of unity are the three roots of the equation

$$x^3 - 1 = (x-1)(x^2 + x + 1) = 0;$$

calling them $1, \alpha_1, \alpha_2$, we have obviously for the two *imaginary* cube roots of unity

$$\alpha_1 = \frac{1}{2}(-1 + \sqrt{-3}) \text{ and } \alpha_2 = \frac{1}{2}(-1 - \sqrt{-3})$$

It is manifest that $\alpha_1 + \alpha_2 = -1, \alpha_1 \alpha_2 = 1$ and hence $\alpha_1^2 = \alpha_2, \alpha_2^2 = \alpha_1$; so that representing by a either of the imaginary cube roots of unity, the three roots of the *pure* cubic equation $x^3 = a$ are $\sqrt[3]{a}, a\sqrt[3]{a}, a^2\sqrt[3]{a}$; where the symbol $\sqrt[3]{a}$ denotes the ordinary *arithmetical* cube root of a . [CUBIC EQUATION.]

Cubeba. A genus of *Piperaceae*, distinguished by its diocious flowers being partly covered by sessile bracts, and by its fruits being elevated on a sort of stalk, formed from the contraction of the base of the fruit itself. *C. officinalis*, formerly *Piper Cubeba*, furnishes the Cubebes of commerce.

Cubebes. The berries of the *Cubeba officinalis* or *Java pepper*. They have a bitter and aromatic flavour, and contain volatile oil and resin: they are stomachic; and given in a dose of from one to two drachms in powder, two or three times a day, have proved curative in certain forms of *gonorrhoea*.

Cubic. In Algebra, denotes a homogeneous function of the third degree in its variables; in other words, a quantic of the third order with respect to its facients. The general form of a *binary cubic* is

$$(a, b, c, d)(x, y)^3 = ax^3 + 3bx^2y + 3cxy^2 + dy^3,$$

equated to zero it gives the general cubic equation, having the ratio $\frac{x}{y}$ for its unknown term. Such a cubic has but one invariant, viz. its discriminant

$$a^2d^3 + 4ad^2c + 4db^3 - 3b^2c^2 - 6abcd.$$

With respect to its covariants, the most important is its Hessian, which has the same discriminant as the cubic itself.

The solution of a *cubic equation* obviously resolves itself into the transformation of the above general cubic to its *canonical form* $AX^3 + BY^3$, by means of linear substitutions $X = \alpha x + \beta y$ and $Y = \alpha_1 x + \beta_1 y$. But it follows from the definition of covariants that the same substitutions will reduce the Hessian to the form $ADXY$. So that X and Y are, to a constant *præ*, the two factors of the Hessian, and can be found by the solution of the quadratic obtained by equating the original Hessian to zero. If the roots of the Hessian are real, two of the roots of the cubic will be imaginary; if the former are imaginary, however, all the three roots of the cubic will be real; lastly, the cubic will have a pair of equal roots whenever its Hessian has. The criterion

CUBIC

in these cases is furnished at once by the discriminant, which is common to both cubic and Hessian; according as its value is positive, negative, or zero, the one or other of the above three cases will arise.

A *ternary cubic*, equated to zero, represents in coordinate geometry a *plane cubic curve*. The canonical form to which every such cubic is reducible is $x^3 + y^3 + z^3 + 6mxyz$. A ternary cubic has two *fundamental* invariants, which were discovered by Aronhold. (Crelle's *Journal*.) One is a quartinvariant, which for the canonical form reduces to $S = m - m^3$; and the other a sextinvariant, which for the same form has the value $T = 1 - 20m^2 - 8m^3$. Sylvester has shown (*Philosophical Magazine* 1853, and *Cambridge and Dublin Mathematical Journal*) that every other invariant of a ternary cubic may be expressed as a rational function of these two fundamental ones. For instance, its discriminant, which is an invariant of the twelfth order, is $T^2 - 64S^2$. With respect to the covariants of a ternary cubic, we will only mention here that its Hessian is another cubic, which for the canonical form is expressed thus:

$$m^2(x^3 + y^3 + z^3) - (1 + 2m^3)xyz.$$

The very important properties of ternary cubics will be found scattered in the more recent journals. Hitherto the only attempt to collect them has been made by Dr. Salmon, whose excellent little treatise on the Higher Algebra will be of great assistance to every student of the subject. Quaternary cubics have as yet been little studied. From their connection with cubic surfaces, however, they possess great interest.

The term *plane cubic*, as above remarked, is applied to plane curves of the third order. Since the publication of Newton's *Enumeratio Linearum Tertii Ordinis*, their properties have formed the subject of very numerous investigations. Cubics are naturally classified according to the number of tangents that can be drawn to them from any point in the plane. Thus we have *cubics of the sixth class*, which have neither double point nor cusp; *cubics of the fourth class*, which admit of two varieties according as the only double point which they can possess is a conjugate point or a node; and *cubics of the third class*, which have a cusp, but of course no double point. Another classification is based upon the number and nature of the points of intersection with the line at infinity; and a third on the harmonic properties of cubics. [CHARACTERISTIC OF A CURVE.] One of the most instructive classifications, however, is due to Newton, who has shown that every cubic is the projection or shadow of a kind of parabola whose equation may be written in the form

$$y^2 = A + Bx + Cx^2 + Dx^3 \\ = \lambda(x-a)(x-b)(x-c).$$

Of the parabolas represented by this equation, however, there are obviously five varieties, corresponding to the cases when, of the three quantities, a, b , and c , (1) two are imaginary;

(2) all are real and unequal; (3) the two least are equal; (4) the two greatest are equal; and (5) all three are equal. Besides Newton's classification of cubics, there are others by Euler and Cramer. We have also an elaborate one by Plücker, who distinguishes 219 different varieties (*System der Analytischen Geometrie*); another by Möbius, who divides them into seven species, by considering their central projections on a sphere (*Grundformen der Linien der dritten Ordnung*, Leipzig 1849); and another by Bellavitis (*Memorie della Società Italiana*, t. xxv. 1855).

The Hessian of a cubic, or the locus of a point a , whose polar conic breaks up into two right lines, is itself a cubic. The intersection a_1 of these lines is also on the Hessian, and is called the *corresponding point* of the former point a . The Steinerian of a cubic, therefore, coincides with its Hessian. The envelope α of the lines $a a_1$ is a curve of the sixth order and third class, which has been called by Cremona the *Cayleyan* of the cubic, inasmuch as its properties were first investigated by Cayley (*Phil. Trans.* 1857). Besides the works already cited on plane cubics, many others might be added. We mention only MacLaurin's *Geometria Organica*, Londini 1720; Steiner in Crelle's *Journal*; Chasles and Jonquières in Liouville's *Journal*, and *Comptes Rendus*; Cremona's *Teoria Geometrica delle Curve Piane*; Cayley, Hesse, Clebsch, and others, in Crelle's *Journal*; and Salmon's *Higher Plane Curves*.

A *non-plane or twisted cubic* may be regarded as the partial intersection of two ruled quadric surfaces which have a common generator; for instance, as the intersection of two quadric cones; they are always curves of the *third class*, that is to say through any point in space may in general be drawn three osculating planes.

One classification of non-plane cubics into four species has been based upon the nature of the three points in which such a curve meets the plane at infinity. Thus the *cubical ellipse* meets the plane at infinity in one real and two imaginary points, the *cubical hyperbola* in three real points, the *cubical hyperbolic parabola* in three real points, two of which are coincident, and the *cubical parabola* in three real and coincident points. (Salmon's *Analytical Geometry of Three Dimensions*.)

Non-plane cubics appear to have been first examined by Möbius. (*Barycentrische Calcul*, Leipzig 1827.) Since then Chasles, in his *Aperçu Historique*, in Liouville's *Journal*, and in the *Comptes Rendus*; Schröter and Cremona, in Crelle's *Journal*, and in the *Nouvelles Annales des Mathématiques*, have contributed greatly to our knowledge of the subject. Other memoirs by English writers will also be found in recent journals.

Cubic surfaces have only been partially investigated. Upon them can in general be drawn *twenty-seven* right lines, the properties of which were first investigated by Cayley and

Salmon in the *Cambridge and Dublin Mathematical Journal*, vol. iv. 1849. A classification of cubic surfaces into five species has been based by Dr. Schläefli on the real or imaginary character of these lines. (*Quarterly Journal of Mathematics*, vol. ii. 1858.) In the *Philosophical Transactions* for 1863, however, the same mathematician has given a more elaborate classification of cubic surfaces, into twenty-two species, founded upon their class, which varies from the twelfth to the third, and the number and nature of their nodes. Numerous contributions by Cayley, Salmon, Sylvester, Steiner, Chasles, and others to our present theory of cubic surfaces, are scattered in the pages of recent English and Continental journals and proceedings of learned societies. In Dr. Salmon's *Analytical Geometry of Three Dimensions* alone have the principal results of these investigations been hitherto collected.

Cubic Equation. In Algebra, an equation which involves the cube of the unknown quantity. A cubic equation is said to be a *pure* one, when it consists of two terms only; one of which is a simple number. Thus $x^3 + c = 0$ is a pure cubic equation. All other cubic equations are said to be *affected*. The most general affected cubic equation can obviously be reduced to the form $x^3 + 3a_1x^2 + 3a_2x + a_3 = 0$. The roots of a pure cubic equation are easily found [CUBE ROOT], whilst those of an affected one may readily be deduced from the properties of covariants. [CUBIC.]

An affected cubic equation was first solved, independently, by the Italians Nicholas Tartalea and Scipio Ferrens. Their method of solution, however, was first published by Cardan. It is known as *Cardan's Rule*, and is explained in all text-books.

Cubical Parabola. There are two curves known by this name; one is a non-plane [CUBIC], the other a plane curve. The latter has for its equation $a'y = x^3$; it has a point of inflection at the origin and a cusp at infinity. It is of the third class, and has the origin for centre.

Cubicite. A mineralogical synonym for cubic zcolite or Analcime.

Cubinvariant. [INVARIANT.]

Cubit (Lat. cubitus). In Architecture and Sculpture, a linear measure of the ancients, equal to the length of the arm from the elbow to the extremity of the middle finger, usually considered about eighteen English inches. The geometrical cubit of Vitruvius was equal to six ordinary cubits.

Cubitus (Lat.). The fore arm; the larger bone or *ulna* of which is called the *os cubiti*. This term is said to be derived from *cubo*, *I lie down*, from the custom of leaning on that part of the arm in the recumbent posture at meals.

Cuckoo. [CUCULUS.]

Cuculinæ (from Lat. cuculus, a cuckoo). A name given by Latreille to a family of bees, distinguished by the absence of the femoral plates for transporting pollen, and which are consequently compelled to resort to the combs of other bees in order to deposit their eggs:

CUCULUS

hence they may be regarded, like the cuckoo, as a kind of parasite.

Cuculus (Lat. a *cuckoo*). A most interesting genus of Passerine birds, belonging to that group which is characterised by having the toes situated two before and two behind (*Zygodactyls*), and so named from including as the typical species the common European cuckoo (*Cuculus canorus*). The cuckoo is a migratory bird; it arrives in England in the month of April for the purpose of breeding. It differs from almost every other bird in not constructing a nest, nor under any circumstances hatching its own eggs, which it deposits in the nests of other birds, as of the hedge-sparrow. The unfledged young have a remarkable instinct, which impels them to unceasing effort to expel their helpless companions from the nest, which they effect by pushing them in the hollow of their back to the verge of their nest, and tilting them over, until they at length monopolise all the care and provision of the foster-parent. The young cuckoos of the year do not leave this country till the month of September.

Cucurbitaceæ (Cucurbita, one of the genera). A natural order of diclinous Exogens, inhabiting the hot countries of both hemispheres. They are placed by Auguste de St. Hilaire and De Candolle between *Myrtaceæ*, to which they appear to have little affinity, and *Passifloraceæ*, to which they are so closely allied that they differ only in the sinuous stamens, unisexual flowers, inferior fruit, and exalbuminous seeds. The order is one of the most useful in the vegetable kingdom, comprehending the Melon, Cucumber, and the various species of Gourd. The Cucumber is the fruit of *Cucumis sativus*, the Melon of *Cucumis Melo*; while the Gourds, Vegetable Marrows, Pumpkins, &c. are species of *Cucurbita*. Colocynth is the pulp of *Citrullus Colocynthis*, which is a drastic purgative and intensely bitter. The perennial roots of all the order appear to contain similar principles; especially that of the *Momordica E'ateriaum*, now *Eccalium agreste*, which yields the virulent purgative called *clatine*.

Cudbear. The commercial name of *Litmus*, and some other blue and red dyes, derived from certain Lichens. The name seems to have originated from that of their first manufacturer, Cuthbert Gordon.

Cuddy. In small vessels, the name applied to the part where the cooking of the men's rations is carried on.

Cuirass (Fr. cuirasse, from cuir, *leather*). A covering for the breast; originally, as the name denotes, of leather, also of quilted linen, cloth, &c. The cuirass of plate-armour succeeded the hauberk, hacqueton, &c. of mail, about the reign of Edward III.; and from that period the surcoat, jupon, &c., which were usually worn over the coat of mail, began to be laid aside. From that period the cuirass or breastplate continued to be worn, and was the last piece of defensive armour laid aside in

CUMIN SEED

actual warfare. There were cuirassiers in the English civil wars, and in the French service nearly to the end of the seventeenth century; after this period, the cuirass was generally laid aside, until it was again employed by some of Napoleon's regiments, and it is now, in most services, worn by some regiments of heavy cavalry. **Cuissas, Cuissots, Cuissarts, &c.** (Fr.). In Plate Armour, the pieces which protected the front of the thigh.

Culdees. A religious order, whose origin is attributed to St. Columba, an Irish monk of the sixth century, who evangelised the western parts of Scotland, and founded a monastery in Iona. The word is probably contracted from the Gaelic *Gille De* (or servants of God), words corresponding to the Latin *Cultores Dei*. (Hook's *Church Dictionary*.)

Culex (Lat. a *gnat*). A Linnean genus of insects, having the common gnat (*Culex pipiens*, Linn.) for its type; but now raised to the rank of a family (*Culicida*), including the genera *Megarrhina*, *Sabethes*, *Ædes*, *Arophetes*, and *Culex* proper: the two latter are British.

Cullet. The term given to broken glass brought to the glass-house for the purpose of being melted up with fresh materials.

Culm. A provincial synonym of *anthracite*. *Mineral carbon, glance coal, columnar coal*, are terms also applied to this species of coal, of which Kilkenny coal furnishes an example.

CULM. The stem of grasses, which is hollow and has a peculiar organisation.

Culmination (Lat. culmen, *the top*). The passage of a celestial body over the meridian, at the upper TRANSIT [which see].

Cultivator. An implement of the horse-hoe kind, chiefly used in working fallows. It consists of a frame of iron, into which a number of coulter, or tines, are introduced; which, when the instrument is drawn along lands already ploughed, penetrate to the bottom of the furrow, and thoroughly pulverise the soil.

Cultrate (Lat. cultratus, from culter, a *knife*). Coulter-shaped, as when a body is straight on one side and curved on the other.

Culverin (Fr. couleuvrine, from Lat. colubra, a *serpent*). A cannon of the sixteenth century, at which time cannon were named after serpents, &c. It carried a shot of about 18 lbs. weight. A demi-culverin was about a nine-pounder.

Culvert. An arched channel of masonry, built beneath the bed of a canal, for the purpose of conducting water from under the same; in this sense it may be either a siphon or a surface drain. It is applied in the sense of an arched drain in engineering works upon railways, or analogous structures.

Cumin Seed. The seed or fruit of the *Cuminum Cuminum*. It is imported from Sicily and Malta. It forms an ingredient in *curry powder*, and in some kinds of cheese; it has also been used medicinally, but is unimportant. It has a very peculiar odour, and a bitter and aromatic taste. In poultices and plaisters, it is supposed to promote the dispersion of indolent

CUMINIC ACID

tumours. Some of the Roman poets allude to its power of producing pallor and languor. The essential oil of cumin seed is a mixture of a hydrocarbon termed *cymol* ($C_{20}H_{14}$), and of an oxyhydrocarbon called *cuminol* or *hydride of cumyl* ($C_{20}H_{12}O_2 + H$).

Cuminic Acid. An organic acid, formed when oil of cumin is added to fused hydrate of potash. It crystallises in colourless plates.

Cumulant (Lat. *cumulans*, part. of *cumulo*, *I heap up*). A term given by Sylvester (*Phil. Trans.* 1858) to the numerator or denominator of the convergent of a continued fraction. [CONTINUED FRACTION.]

Cuneate (Lat. *cuneatus*, from *cuneus*, *a wedge*). An animal or part is so called which has the longitudinal diameter exceeding the transverse, and narrowing gradually downwards.

Cuneiform Letters, called *Keilschriften* by the Germans (Lat. *cuneus*, *a wedge*). The name given to the inscriptions found on old Babylonian and Persian monuments, from the characters being formed like a wedge. This species of writing, as it is the simplest, so it is the most ancient of which we have any knowledge.

About eighty years ago, a few specimens of inscriptions existing at Persepolis found their way into Europe, and the attention of the learned was directed to the subject. Many German philologists, at the head of whom was the celebrated Tychsen, applied themselves to the task of deciphering and translating these inscriptions with an unrivalled energy and enthusiasm. It was not, however, till the commencement of the present century, when Dr. Grotefend of Hanover engaged in the pursuit, that the mystery in which this species of writing had for so many centuries been involved began to be cleared up. According to him, this mode of writing is formed of two radical signs—the wedge and the angle—susceptible, however, of about thirty different combinations; and consists of three varieties, distinguished from each other by a greater or less complication of the characters. It is of Asiatic origin; is written from right to left, like the Sanscrit; differs from the ancient Egyptian hieroglyphics, inasmuch as it is alphabetic, not ideographic; and, finally, with a few considerable modifications, forms the basis of most of the Eastern languages. The views of Dr. Grotefend received striking confirmation from the researches of Mr. Rich. A full exposition of this species of writing would prove one of the most valuable accessions to modern literature; but the only direct results by which this study was long followed may be stated to be the translation of a few minor inscriptions, and the establishment of a canon so extremely arbitrary, that it was very problematical if the labours of others in the same field could be materially benefited by it. Within the last few years a new impetus has been given to the prosecution of this study by the numerous facts brought to light on the spot through the intrepidity of Botta, Rawlinson, and Layard; but the method of interpreting these inscriptions and the certainty of its results have recently

CUNEIFORM LETTERS

been called in question by Sir G. Cornewall Lewis, in his work on the *Astronomy of the Ancients*.

The origin of the cuneiform letters has more lately engaged the attention of Mr. James Nasmyth, to whom we are indebted for the following remarks:—

‘There appears to be one general principle to which the distinctive form of all alphabetic writing owes its origin, namely, the peculiar nature of the materials employed in the primitive ages of the people who originated the alphabetic character in question. Whatever be the material employed to write upon or write with, the nature of the material will be certain to influence the form of the character produced; so much so, that however time and circumstances may cause a change in the selection of materials employed, a greater or less traditional exactness will be adhered to in the copy of the original prototype character.

‘Among the many examples which attest this fact, there does not exist a stronger one than in the case of the cuneiform character, which had its origin in the fact of the early Assyrian nations employing the mud of their river banks as their building material in the form of bricks. To that circumstance we may most reasonably trace and assign the origin as well as the peculiar form of the cuneiform character. Not only does the cuneiform character make its earliest appearance in bricks and pottery, but it is so absolutely identified with plastic material, that in order to reproduce it in its original integrity of form, as well as by the most simple means, we must have recourse to clay, in the condition of a soft brick for our tablet, and the corner angle of a dried brick for our “style” or inscribing implement.

Fig. 1

‘Reference to fig. 1 will show how perfectly these simple agents will enable us to produce the cuneiform character.

‘Accident or intention may thus have produced it in the first instance, and led to the use of a more handy tool for inscribing than the corner angle of a dried brick; certain it

CUNEIFORM LETTERS

is, however, that the corner angle of a dried brick will give us the means of inscribing on the side of a soft brick or clay tablet every size and variety of cuneiform character, and in the absence of any certain in-

Fig. 2

formation on the subject this may be taken as a reasonable explanation of its origin. Be that as it may, there can be no doubt as to the fact that in its earliest stages of development it was written on surfaces of soft clay by means of a "style," having all the structural powers or inscribing properties of the corner angle of a brick, with the advantage of greater handiness. That such was the form of the style employed and such its mode of use, the author had the good fortune to prove by the discovery

Fig. 3

of a large Assyrian brick among the cuneiform characters on which the "style" had been so deeply impressed as to leave an absolute record of its size and exact form.

'It is one of the many remarkable qualities of this strikingly beautiful alphabetic character, that the selfsame "style" can produce any size

CUPIL

and variety of character by simply modifying the extent of depression into the clay surface or by varying the position of the axis of the style as to direction, or angle of depression in respect to the surface of the clay tablet.

'However complete the arrangement of the character, or varied the size of the letters or words, if we may so term them, they are all

found to consist of the one element which

so distinctively marks this character.

'When the cuneiform came to be applied to hard materials, certain slight modifications of form were introduced, but in no case greater than might be expected from change of material, time, and people. The clay prototype proclaims itself to the eye; and such was the pertinacity of traditional adherence to the cuneiform original, that even when ages had passed and the very language disappeared and became changed to the Greek, as in the case of the Assyrian-Greek collections, the Greek letters cut in marble by these people and their descendants have the cuneiform character strongly marked in them, as the most cursory glance at such Greek inscriptions will abundantly testify, as thus:

and in conclusion it may be well to remark, as an instance of the pertinacity with which certain shapes and forms are clung to long after the causes that led to their origin have departed, that in the capital letters of our modern alphabet we find in the cross-strokes of such capital letters unmistakable evidence of cuneiform origin in the feature in question. The only variation in the modern letter is this: the cross stroke is parallel to the line of letters or at right angles to it, whereas in the Assyrian-Greek inscriptions it is at right angles with the axis of the limb of the letter,

as thus: each limb being in fact

a cuneiform.' [ALPHABET.]

Cunette (Fr.). In Fortification, a narrow ditch in the middle of a dry ditch, serving as a drain, or if filled with water, as an obstacle to the enemy.

Cunoniaceæ (Cunonia, one of the genera). A natural order of arborescent or shrubby Exogens, inhabiting South America and the East Indies; allied so intimately to *Saxifragaceæ*, that they are only distinguished by their arborescent habit and interpetiolar stipules. The bark of some species is used for tanning leather.

Cupel (Fr. coupelle). A shallow and porous earthen vessel, somewhat of a *cup* shape, generally made of bone earth. It is used in the assays of the precious metals, which are fused upon a cupel with lead. *Cupellation* means the refining of gold or silver upon a *cupel*.

Cupid (Lat. Cupido). The Roman name of the god of love. Cicero speaks of three

CUPOLA

divinities under this appellation (*De Nat. Deor.* 3. 23.); but the one usually meant when spoken of without any qualification was the son of Mercury and Venus. He is generally represented as a beautiful child with wings, blind, and carrying a bow and quiver of arrows. [Æros.]

Cupola (Ital.). In Architecture. [DOME.]

CUPOLA. The term applied to the furnace used in batteries for heating shot to be fired against shipping.

Cupping (from the *cup shape* of the glasses used in its performance). In this operation a cup-shaped glass is used, into which the large flame of a spirit lamp is momentarily introduced, so as to expel a great part of its air by dilatation; it is then instantly applied to some part of the body, which is forced into it by the external pressure; and on removing the glass a circular red mark is left, from the propulsion of the blood into the small vessels of the part: this is called *dry cupping*. It is generally followed up by making a number of incisions in the part by means of an instrument called a *scarificator*, from which the blood oozes, and from which a considerable portion may be drawn by again applying the cupping glass. Cupping, when well performed, is not a very painful or disagreeable operation, and is an excellent mode of local blood-letting. When the operator is not dexterous, it is not only painful, but often dangerous in its consequences. The bleeding may generally be easily stopped by a piece of lint or soft rag; but this should be looked after, as instances have occurred of persons bleeding to death from the wounds of a scarificator.

Cuprammonium. The hypothetical positive radical of a salt obtained on passing ammoniacal gas over hot chloride of copper.

Cupric Acid. A peroxide of copper supposed to be formed when copper, potash and nitre are fused together.

Cuprocyanogen. A compound radical contained in the double cyanide of copper and potassium.

Cuproplumbite. A double sulphide of lead and copper found in Chili, in granular masses of a lead-grey colour, with a metallic lustre and a cubic cleavage.

Cupule. In Botany, the cup or husk of the acorn and similar fruits, forming a sort of involucre.

Cupulifera or **Cupbearers**. Another name for the *Corylaceæ*.

Curacao. A liqueur which derives its name from the island of Curacao. It is prepared in great perfection by the Dutch, and derives its flavour from Seville orange peel, with a small quantity of cinnamon and mace.

Curarine. An alkaloid contained in *Curara*, the Ourari, Wourali, or Arrow Poison of the South American Indians.

Curassoe. [CRAX.]

Curate (Lat. *curare*, to take care). Properly, an incumbent who has the cure of souls; now generally restricted to signify the spiritual assistant of a rector or vicar in his cure.

CURCAs

Curates form the lowest order of the clergy; and are divided into two classes, perpetual and stipendiary. 'Perpetual curates are such as are appointed to the churches of those parishes in which the tithes were appropriated to some monastery before the statute 4 Hen. IV. making it necessary to endow a vicar, or which had from some cause or other escaped its operation;' or they are such as officiate in some chapel: in either of which cases, their salary is usually paid by some fixed payment, or by a portion of the tithes appropriated for their maintenance at the foundation of the chapel. Stipendiary curates are such as are appointed by the vicar or rector to officiate at their churches in their stead. As to these, the law was regulated in 1838 by the Act 1 & 2 Vict. c. 106, which gives the bishop power to require their appointment, or himself to appoint, where the incumbent is non-resident, or the duties are inadequately performed, &c., and in large benefices (above 500*l.* per annum and 3,000 population) in addition to the resident incumbent. Salaries to be fixed according to the scale appointed by the Act. In cases of non-residence, the curate is to be allowed under certain restrictions the use of the parsonage house, (Cripps, *Law relating to Church and Clergy*, 1857.)

Curator (Lat.). In a general sense, signifies a person who is appointed to take care of anything. Among the ancient Romans, there were officers in every branch of the public service to whom this appellation was given: thus we read of *Curatores aquarum, frumenti, viarum, operum publicorum, Tiberis*, &c. &c.: i.e. persons who distributed corn, superintended the making of roads and the public buildings, or were conservators of the river, &c.—Curator, in the Civil Law, is the guardian of a minor who has attained the age of fourteen. Before that age, minors are under a tutor. The guardianship of persons under various disabilities, and of the estate of deceased or absent persons and insolvents, is also committed to a *curator*. In learned institutions, the officer who has charge of libraries, collections of natural history, &c. is frequently styled *curator*.

Curb Roof. In Architecture, a roof in which the rafters, instead of continuing straight down from the ridge to the walls, are at a given height received on plates, which in their turn are supported by rafters less inclined to the horizon, whose bearing is through the medium of the wall plates, directly upon the wall. It presents a bent appearance, as in the diagram, whence it derives its name; it is also called the *Mansard roof*, from the name of the celebrated French architect who very frequently resorted to its use.

Curass. A genus of *Euphorbiaceæ*, comprising the Physic nut, *C. purgans*, a plant which differs from *Jatropha* in having a bell-shaped instead of a five-petaled corolla. It is a bush of tropical America, cultivated for the purgative oil of its seeds.

CURCULIO

Curculio (Lat. *a weevil*). A Linnæan genus of Coleopterous insects, now the type of an extensive family, *Curculionide*, or weevils belonging to the Tetramerous section of the order. The prolongation of the anterior part of the head, in the form of a proboscis or snout, at once distinguishes the insects of the present family from all other beetles. The number of the *Curculionida* may be imagined when it is stated that entomologists have found it necessary to distribute them into nearly three hundred subgenera. They are all vegetable feeders, and include some of the most dangerous enemies to the vegetable stores of mankind.

Curcuma (Arab. *kurkum*). This genus of *Zingiberacea* yields Turmeric and Zedoary, the former being produced by *C. longa*, the latter by *C. aromatica* and *C. zedoaria*. The tubers are the parts used, and they are pleasant aromatics. Turmeric enters into the composition of curry powder.

Curcumin. An amorphous resinous colouring matter contained in turmeric root.

Curetes (Gr. *Κούρητες*). In Greek Mythology, the Cretan attendants of Zeus, or Jupiter, who watched over him in his infancy. In the *Iliad*, the Curetes are mentioned as the adversaries of the *Ætoli*ans, who were defeated by Meleagros at Calydon. (Thirlwall, *History of Greece*, vol. i. ch. iv.) [CORYDANTES.]

Curfew (from the French *couvro-feu*, in modern Latin *ignitegium*). The practice of tolling the church bell at eight or some other hour in the evening, to warn people to extinguish their fires, was a very common one in the middle ages. It is difficult to say on what foundation the common tradition, that William the Conqueror introduced it from Normandy to prevent the English from assembling in the evening to plan schemes of rebellion, rests. It is more probable that the Conqueror enforced a very common police regulation. The real reason of the curfew was to prevent fires. The custom of ringing the evening or curfew bell is still retained in many places. (Brand's *Popular Antiquities*, vol. ii. pp. 136, 137.)

Curia (Lat.). [CURIES.]

Curies, Curies (Lat.). A subdivision of the Roman patrician tribes, each of which were divided into ten *curies*. These *curies* probably contained originally ten houses (*gentes*) each. These houses were similar to the Scottish clans, in which, though the bond of union was supposed to be that of common blood, yet in reality there was no consanguinity between many of the component families. The building in which the senate held its meetings in Italian cities was called *curia*. There were several such curiæ in Rome.

Curl. A disease in potatoes, in which the leaves on their first appearance appear curled and shrunk up; and consequently, as they do not present a sufficient surface to the light to elaborate the sap in a sufficient manner for carrying on the growth of the plant, it never acquires strength, and either dies, or produces very imperfect tubers. The cause of the disease

CURRENCY

in the first instance is generally supposed to be the unhealthy state of the set; but something also may be owing to bad management and improper soil.

Currant. The fruit of two species of *Ribes*; namely, *R. rubrum*, which furnishes the common red and white currants; and *R. nigrum*, which produces the black currant. The currants of the grocers' shops (so called from Corinth, as the chief mart for this fruit) are the dried berries of a small species of grape cultivated in Zante, Cephalonia, and Ithaca; and in the Morea in the vicinity of Patras. These so-called currants are largely imported into Great Britain, and the entries of currants for home consumption for the year 1863 amounted to 768,312 swt., of the computed real value of 981,137*l.*, and yielding in the form of customs duties 268,924*l.*

Currency (from Lat. *curro*, *I run*). In Political Economy, a generic term employed to designate the conventional measure of value, whether the measure be immediate, as gold and silver coin, or substitutive, as bank-notes and their analogies. The term *Money* will be treated below, and will be limited to the sense of a metallic circulation; at present we may make a few remarks on the wider and more significant word, *currency*.

The recognition and employment of a measure of value is as essential to all but the simplest operations of exchange, as the recognition and employment of language is to all but the simplest operations of thought. Society exists by the interdependence of individuals, and in the reciprocity of services; the progress or development of society, from an economical point of view, consisting in the continual subdivision of occupations, for the purpose of greater efficiency and economy in the production of whatever objects form the services or utilities offered. But in order that these services should be rendered, they must be called into existence by demand, and this demand can be effectual only when a service of another character is offered, the significance of which is sufficient to dispose to an exchange between the two services or utilities. With a view to the determination of such an act of exchange, it is almost always necessary that the respective utilities or services should be measured by some standard of value well and familiarly understood between the contracting persons, and this standard must be of such a kind as is liable, among other qualities, to the fewest possible fluctuations in its intrinsic or absolute value. For the same reason of comparative invariability in absolute value, this conventional measure will also satisfy another essential condition; that, namely, of being universally acceptable as a means for interposing a period, more or less protracted, before the entire completion of an act of exchange. For example, A produces shoes and B produces bread. But A may want bread before B wants shoes. The exchange, however, between the parties may still take place by the intervention of currency. If B receives this medium, he takes

CURRENCY

it on the faith that, whenever he pleases hereafter, he may complete the exchange with A by the purchase of shoes, or may employ the right to shoes assigned to him by the transfer of a portion of currency, in procuring any other utility which he may desire. Hence a sale has been said to be half an exchange.

If we bear in mind that the radical significance of a currency lies in the facts of its being acceptable on the ground of its generally equal or persistent value, and of its satisfying a seller from its being transferable for nearly equal quantities of utilities at a deferred period, we shall find no great difficulty in interpreting almost all practical questions which arise in connection with currency. The basis of a circulating medium must be a commodity which, being produced in nearly equal quantities by nearly equal labour, is, as has been said, of nearly equal absolute value. If two commodities of this kind are discovered and employed, they must not only possess, separately, the characteristic of general invariability, but if both are employed simultaneously as media of exchange, they must possess also a relative invariability. (See below, *Double Currency*.)

Now, nothing has yet been discovered which possesses separately or relatively these characteristics except the metals gold and silver. Not that this quality is the sole cause for the general acceptance of these commodities as media of exchange, but this is the fundamental and essential reason for their selection. The existence of a measure of exchange is a primary condition of economical society; it may be to some extent satisfied, in the total absence of the precious metals, by the substitution of a fictitious measure; and some of the native tribes in the interior of Africa, where the precious metals are unknown, are said to use a mere mental fiction in order to measure values; but it is impossible fully to satisfy the conditions of the act of exchange, except by the interposition of these metals, or, if it might be discovered, by some other commodity possessing in a still more distinct manner the characteristics of gold and silver.

These metals, then, form part of the machinery of exchange; an expensive part, because, as we have seen, they are selected at once from the fact of their exceptional fitness for the function they fulfil, and because they cost great labour in the acquisition. Were they procured cheaply, even though the condition of equal quantities of labour were continued in their production, much of this utility would be lost, because, though still an efficient measure of value, they would be cumbersome and inconvenient. To retain their place, they must be *dear*.

It must be borne in mind that the agent in any economical process is always striving to procure or produce the greatest possible results with the least possible expenditure of labour. This natural impulse is further intensified by the principle of competition. Labour, to have a value, must be undertaken for some ulterior purpose, and, if we say that each person desires

to get an increasing quantity for his labour, we are only stating in a different set of words that he wishes to shorten or economise his labour as much as possible, and to exhibit equal or greater results at less cost. Hence it is that labour is divided, and that all possible forces, natural and artificial, as, for instance, the natural force of running water and the artificial force of steam, are appropriated by the ingenuity of man—an ingenuity developed, as far as society is concerned, wholly from the principle of competition.

Now what applies to individuals applies also to society at large, or rather to political communities. They desire, unconsciously perhaps, but quite as effectively, to diminish, as far as possible, the expense attending the employment of the machinery of exchange. Hence, even in the face of all the administrative restrictions imaginable, they will always employ just as much of these precious metals for the purposes of exchange as they need, and no more. The quantity needed varies very little when the process of exchange is regular and undisturbed, but increases and diminishes by the pressure of certain events, or even by the contingency of these events. As an inference from what has been stated, there is always a tendency towards diminishing the quantity of the currency to the least possible amount consistent with the wants of the community, and the forecast of these contingencies, while all laws and regulations, however much they may multiply or precipitate these contingencies, are inadequate to prevent any evasion by which every possible economy in this expensive material may be achieved.

One of the earliest means by which this economy is effected is by the substitution of tallies or tokens for the metallic currency itself. Even if this substitution had nothing to recommend it but the saving of wear and tear in the metals, and in the supply of a means for more readily identifying and securing the right to a claim on the metal by the presentation and delivery of the tally or token, the means in question would have a great importance in diminishing the cost of the monetary machinery. Hence, in the imperfect economies of the ancient and mediæval world, substitutes for metallic currency were well known, in the shape of banker's tallies and bills of exchange. It will be manifest, if an actual transfer of cash from one town to another were necessary in all transactions between the trades of either locality, that a far larger amount of metallic currency would be needed than is actually required when letters authorising mutual payments take the place of such a metallic transfer. Whether, indeed, these tallies and bills of exchange were circulated by transfer or endorsement in those remote periods or not, is a question difficult to determine.

Modern societies, however, have not been slow to discover that certain documents purporting a right to claim a specified portion of the precious metals at a specified place or places, are, provided they can be framed in such a way as makes fraud practically impossible, a powerful means towards an economy of the expensive

CURRENCY

machinery of the precious metals. Of course, the acceptance of such a document in lieu of the metallic currency is only possible in case the recipient has no doubt that he can appropriate, at his pleasure, the amount specified in the instrument. But if this confidence exists, the paper will have all the practical value of the metals or coins which it represents, in somewhat the same way as writing will represent language, and be received in communications as equivalent to spoken words.

This, however, is not all the effect even of the most familiar of these representations of money, the bank-note. It has been found possible to calculate in a general way, and with every allowance for contingencies, the amount of metallic currency which will be demanded in exchange for these notes. This amount falls far short of the quantity which society will accept and circulate. Not, indeed, that it will circulate a single note beyond its collective needs. Society is no more disposed to accept and use any superfluous quantity of these notes, than willing to circulate more than the requisite quantity of the precious metals. As has been proved over and over again, any attempt on the part of bankers to employ this form of issue beyond the needs of the public is a certain failure, provided, of course, that no compulsion is used to circulate the note; or, in other words, provided the note in question is convertible into cash at the discretion of the holder. The public may, and indeed often does, demand more of these notes than the bank is empowered or disposed to issue, but it will never use more than it wants. And it wants, in the ordinary course of trade, as much of these notes as will enable it to dispense with as much as possible of the expensive machinery, coin. And thus the issue of bank-notes makes it possible for a community to abandon, to some extent, the use of the precious metals, and to make a real and comparatively inexpensive addition to its measure of value.

It would be, however, a great mistake to imagine that coin and notes were the only forms of currency. Whatever is a substitute for metallic money is as effectually a kind of currency as gold and silver are, and fulfil just as completely the functions of these commodities. The use of banker's cheques, of private cheques, of bills of exchange, and all other analogous securities, is in reality a substitution of a cheap for an expensive machinery. It would be idle to speculate on the question whether it would be possible for commerce to be carried on, were these expedients abandoned; but of one thing we may be quite sure, that, if they were not used, the amount of the precious metals necessary to liquidate the common business of the country would be four or five times greater, at the least, than what is necessary now, and therefore cost a great deal more. For instance, suppose the amount of gold and silver needed by the public were one hundred millions, and the abandonment of the system of substitutive currency necessitated a multiplication of this amount by five, we should put what would be practically a debt

of four hundred millions on the nation, without any real value received.

It will not be difficult perhaps to see, under these circumstances, why it is that the creation of these additional forms of currency (always, be it remembered, worth anything only on the full confidence that they are convertible into cash at the personal discretion of the holders) has at different periods produced so marked and beneficial an effect on the general resources of the community which has adopted them. The existence of commercial confidence is in itself a great stimulus to industry; the actual addition to the currency is another cause; the economy of the machinery of trade is a third. When the circulation is purely metallic, its course is languid, and its quantity is indeterminate; but when the securities referred to have been created, they exist entirely for the purpose of trade, and individually fulfil many more acts of exchange than an equal amount of the precious metals could possibly accomplish.

The effects, indeed, of adopting these substitutes, are so singular and immediate, that we need not marvel at the fact that many fallacious interpretations have been put upon them, and even that occasionally some courses of action have been entered on, in which, by the simulation of some among the characteristics of a sound substitutive currency, and the omission of others, consequences destructive in the worst sense have ensued.

The reader will bear in mind, that the only basis for these securities is the confidence of the holder that they can be transformed at his discretion into that which alone, ultimately and fundamentally, fulfils the conditions of a currency—the precious metals. But persons have occasionally imagined that it would be possible to circulate notes expressed in money values, but based on other values, as land, shares in companies, public debts, and the like. No harm ordinarily ensues to society at large when such notes are convertible, because, as we have said, no individual will take them for more than they are worth, nor will society accept more than it needs. But it occasionally happens that the experiment is made by governments, or is enforced by governments under the machinery of a compulsory circulation. In this case the failure of the scheme is inevitable, the consequences are disastrous, the suffering is extreme, and the injury to credit is lasting. In the first place, to promise money, and give something else, is a fraud; and in the next, what people want as a means of exchange, is not money's worth, but money. The very fact of a compulsory circulation is an indication that the currency is not, on its own merits, worth its nominal value, and that, consequently, the issue is as great a robbery on the public as the circulation of base money. In practice the evil is greater, because it takes but a very short time for these securities to become worthless, when their repudiation is inevitable. Such was the history of Law's bank under the Regency, of the South Sea bubble, of the French assignats

CURRENCY

and mandates, and, in a degree, of the American currency during the War of Independence. It would seem that the French and the Americans are peculiarly liable to this monetary fallacy, for there have been occasional indications of an attempt on the part of the former people to employ the securities of the *Crédit Foncier* as a form of currency, and the history of banks in the United States has too often been a mere record of these mischievous and destructive schemes.

On the other hand, the policy of the government of this country, under the auspices of Sir Robert Peel, has been restrictive; the power of issuing notes being at once limited in amount, and assigned practically to a single corporation; for the issues of the county banks form but an inconsiderable portion of the gross amount of notes in the hands of the public. It is not possible to enter here into the details of this celebrated measure, and the reader is referred to the authorities quoted below. But, *prima facie*, the Bank Act of 1844 sins against the principles of free trade. It professes to give a security to the note, when it would seem that the most efficient security, one that has never been wanting in the past history of the bank, lay in the confidence of the public; and it absolutely prohibits the issue of such accommodation as the varying exigencies of the circulating medium require. It has always broken down under pressure, as in 1847 and 1857, and assuredly in times of legitimate necessity it raises the rate of discount and depresses trade, not only by the diversion of a larger portion of mercantile profits into the hands of bankers and bill-discounters, but by virtually rendering a profitable trade impossible. It may be perhaps useful to have, for scientific purposes, so delicate a barometer as the register of the bullion in the Bank; but when the abstraction of a small portion of that bullion creates a monetary storm, it may be worth while to consider whether the operation of the Act is not equivalent to wilfully making the vessel of commerce wholly unseaworthy.

It might be acknowledged that the inconveniences of the Bank Charter Act would have been utterly intolerable, had it not been for the economy induced by the machinery of the Clearing House, and by the almost universal adoption of banking accounts. By these means, the insufficient currency is husbanded and reserved. Still, the very machinery by which the evil is met, becomes a means by which the severity of a commercial crisis is aggravated. (Tooke's *History of Prices, and Tracts on the Currency*; Mr. J. S. Mill's *Political Economy*, vol. ii. pp. 202 sqq. ed. 1862; Lord Overstone's *Currency Tracts*; and *passim* the works of McCulloch and Torrens.)

Inconvertible Currency.—Governments sometimes give their own paper, or the paper of some institution under their control, a forced circulation. When a paper currency is convertible, it cannot, as we have seen, be extended beyond the amount, which the community requires.

But when a currency is inconvertible, it may be issued to any amount, and be made to circulate extensively. The immediate effect of such an issue is to displace the metallic currency, which is either hoarded or exported; for the new circulating medium being overvalued by comparison with the metallic currency, and being of compulsory acceptance, no one will pay in the dearer medium. A very small premium on the precious metals is sufficient to banish them from circulation, though, if the issue of compulsory paper be moderate, it may not be very much depreciated. But generally the circumstances under which the expedient of a compulsory paper is adopted, necessitate or suggest an over-issue, and then the depreciation may be very rapid, and ultimately the paper may become even worthless. The rate at which such a paper is circulated, indicated by its metallic estimate in foreign exchanges, is generally proportioned to the extent to which its holders trust to its final liquidation in full, and to the predictions they make as to when that liquidation will take place. It is almost superfluous to say, that this confidence is never very strong; and as, during such a compulsory circulation, the question as to whether a depreciated currency should be ultimately redeemed at its full value is sure to obtain a hearing and be answered by many in the negative, the tendency of such a paper is always to depression.

Double Currency.—The only community in which a legal tender can be now made at pleasure in either of the two metals, gold and silver, is France. By a law of March 28, 1803 (7 Germinal year xi.), the proportion fixed between the two metals was 15½ to 1. This arrangement slightly undervalued the customary proportion of gold, and hence gold was never seen. But since the great discoveries of this metal in Australia and California, the ratio has been slightly reversed, and silver is undervalued. The consequence is, that gold has been to a great extent substituted for silver, and the latter metal exported in vast quantities. It appears likely, however, in consequence of the discovery of new methods for extracting silver from certain ores in which it exists in small but notable quantities, and by the great cheapening of quicksilver, consequent also upon opening mines of this metal in California where it has been found in great abundance, that the margin of oscillation will be considerably narrowed.

The inconveniences of a double currency are obvious. In the first place, if the oscillations are rapid and considerable, it gives an unfair advantage to debtors. In the second, it induces more fluctuations in the quantity of the precious metals than occur when a single standard only is used, and so renders the foreign exchanges more capricious. Thirdly, it causes that reserves of the undervalued metal should be liable to serious diminution. And lastly, it tends to annul the advantage which the less valuable metal possesses—its use, namely, for small purchases.

CURRENT, MARINE

In our own country, the standard, or actual currency, is gold. Silver and copper are issued, indeed, but are so much overvalued that they could not be exported in the shape of coin; they are therefore secured to circulation, the extent of the overvaluation being regulated so as to obviate the risk of private coining. Silver is overvalued by about 10 per cent., copper by about 100. But silver is no legal tender for more than forty shillings, nor copper for more than twelve pence, or, if offered in farthings, for sixpence. As these tokens are issued by the Mint, they are received at that establishment at their nominal value when worn.

Currency is sometimes used by way of contrast with other rates of value. For instance, at Hamburg, *currency* is opposed to *banco*, the agio in favour of the latter being about 22½ per cent. So in Canada, *currency* is opposed to *sterling*, the agio on the latter being 20 per cent.

Currents, Electric. [ELECTRICITY.]

Currents, Earth. [MAGNETISM.]

Current, Marine. Currents in the ocean arise from various causes, either occasional or constant. They may be occasioned by an external impulsion, as by a gale of wind; from a difference in the temperature of different parts of the sea; from the inequality of evaporation, the melting of the polar ice, or in short any cause tending to disturb the hydrostatic equilibrium. It is difficult in many cases to trace their causes, or to give any satisfactory theory of their existence; but on account of their importance to navigation they have been observed, especially of late years, with great care. Among those which have a permanent or general character, there are two which are very remarkable. The first is that of the tropical waters westward round the globe, and the second that which constantly flows from each pole towards the equator. The tropical or westerly current is chiefly confined within the zone extending to about 30° on each side of the equator, and its velocity is estimated by Humboldt at about nine or ten miles a day. In the Atlantic it separates into two branches; one of which forms the GULF STREAM, and the other flows along the coast of Brazil, and passes through the straits of Magellan.

In the Pacific the currents are not so well known, nor are they quite so definite as in the Atlantic. But there is one group both interesting and important. Commencing as a drift current in the Antarctic Ocean, the water runs along the west coast of South America towards the equator, and then westward, and is gradually converted into the EQUATORIAL CURRENT, which, after crossing the Pacific, enters the Indian Ocean, and passes between Madagascar and the African coast, forming the MOZAMBIQUE CURRENT, and losing itself as it rounds the Cape of Good Hope in the Atlantic Ocean.

Besides the Atlantic and Pacific currents, there are others directly connected with and derived from the Arctic and Antarctic Oceans.

CURULE MAGISTRACIES

[POLAR CURRENTS.] There are also deep currents apparently flowing in directions opposite to those of the surface currents.

The whole waters of the great ocean are thus kept in a constant state of admixture, both with regard to temperature and saltness. The climates of the coasts washed by them are modified, and the general balance of organic life is kept up.

Curriculum (Lat.). The ground traversed in a race, or *course*, and thence, in academical language, the whole *course* of studies completed in a university or similar institution.

Currying (Fr. *corroyer*). The art of dressing skins after they are tanned, for the purposes of the shoemaker, saddler, harness-maker, &c.; or of giving them the necessary smoothness, lustre, colour, and suppleness. The operation of currying is performed in two ways; either upon the flesh (or inner side), or on the hair (or outer side), or, as it is technically called, the *grain*; and consists chiefly in beating or pummelling the skin, smoothing and dressing it, and finally imbuing it with certain oily matters, so as to render it supple and waterproof.

Cursitors (Lat. *cursito*, freq. of *curro*, *I run*). Officers in the Court of Chancery, whose duty it was to make out original writs. Cursitor Baron was the name of an officer in the Court of Exchequer, who formerly administered oaths, &c. These offices are now abolished.

Curtall Step. The lower step in a flight of stairs, ending at its outer extremity in a scroll projecting beyond the ordinary line of the staircase.

Curtain (Fr. *courtine*, Ital. *cortina*). In Fortification, that part of the rampart of the body of the place, which lies between two bastions, and joins their two flanks together.

Curtana. The sword (as it is called) of Edward the Confessor, which has its edge blunted as an emblem of Mercy. It is carried between the swords of justice temporal and justice spiritual, and borne before the kings of England at their coronation.

Curtate Distance. A term employed in Astronomy to denote a planet's distance from the sun reduced to the plane of the ecliptic. The *curtate* (or shortened) distance is therefore equal to the true distance multiplied by the cosine of the planet's heliocentric latitude.

Curtsey or Courtesy of England. In Law, is the right of a husband who has married a wife seized in fee simple or fee tail general, or heiress in special tail, and has issue male or female born alive, and which by possibility may inherit, to hold her lands after her death for his life. [MARRIAGE, LAW OF.] Thus, four things are said to be necessary to give an estate by the curtesy: marriage, seisin of the wife, issue, and death of the wife.

Curule Magistracies. In Ancient History, were those of the greatest dignity in the Roman state; and were distinguished from all others by the privilege enjoyed by the persons who held them of sitting on ivory chairs (*sedes*

CURVATURE

curules) when engaged in their public functions. The curule magistrates were the consuls, prætors, censors, and chief ædiles, which last, on account of this privilege, were called *curule* to distinguish them from the plebeian ædiles.

Curvature (Lat. *curvatura*, a bending). In Plane Geometry, the amount of bending or deflection of a curve from its tangent at any point. The circle, being the curve whose curvature is uniform, is always used, as a measure of the curvature of other curves; that is to say, the curvature at any point of a curve is the same as that of the osculating circle at that point. Now in any circle the deflection from the tangent corresponding to a unit arc is inversely proportional to its radius, so that the reciprocal of the radius of a circle is a measure of its curvature. This granted, the curvature at any point of a curve is expressed by the ratio

$$= \frac{dr}{ds}$$

where ds is the arc-element and dr the angle between two successive normals. This angle, which is obviously equal to that between two successive tangents (angle of contact or contingency), is called also the *angle of curvature*. The radius of the osculating circle, or circle of curvature, as it is often called, is termed the *radius of curvature*; its value in rectangular and polar coordinates is given in all treatises.

Curvature, Absolute. The curvature of the osculating circle of a non-plane curve. The term *absolute* is employed in consequence of such curves possessing a *second curvature* or *torsion* in virtue of which they are continually deflected from a plane.

Curvature, Geodesic. The geodesic curvature at any point of a curve traced upon a given surface is the ratio, to the arc-element of the curve, of the geodesic angle of contact, that is to say, of the angle between the geodesic lines touching the curve at the extremities of this arc-element. The reciprocal of this ratio is termed the *geodesic radius of curvature*,

and its value is $\frac{\rho}{\sin \phi}$, where ϕ is the angle

between the normal to the surface and the principal normal to the curve, and ρ the radius of absolute curvature of the latter. Just as the plane has a geometry of its own, so also has every other surface; right lines on the former represent geodesic lines on the latter, and what was ordinary curvature becomes replaced by geodesic curvature.

The term *geodesic curvature* appears to have been suggested by Liouville, and first adopted by Bonnet in his memoir on the theory of surfaces. (*Journal de l'École Polytechnique*, cah. 32, 1848.)

Curvature, Line of. A line traced upon a surface such that the normals at any two consecutive points meet one another. Since of all the normals to a surface at points consecutive to a given one, only two meet the

CURVATURE, MEASURE OF

normal at that point, and the planes containing the latter normal and the two former are always at right angles to one another, it follows that through every point of a surface pass two lines of curvature which cut one another perpendicularly, and are touched by the two principal normal sections. The normals to a surface along a line of curvature form a developable surface which cuts the given surface perpendicularly, and has with it the curve of intersection for a common line of curvature. This follows as a consequence of the general theorem that when two surfaces cut one another everywhere at the same angle, the curve of intersection will either be a line of curvature on both or on neither. The cuspidal edge of the above developable is a geodesic line on the surface of centres of principal curvature, this surface being such that each of its two sheets is touched by every normal of the original surfaces in such a manner that the tangent planes at the points of contact coincide with the principal planes of section through that normal.

The beautiful and important theory of lines of curvature originated with Monge, and is given in his *Application de l'Analyse à la Géométrie*. His researches have been extended since by others, amongst whom must be mentioned Dupin, to whom we owe the elegant theorem concerning three series of surfaces so related to one another that the surfaces of each series cut all those of the other two series perpendicularly. Any individual of such a system of *orthogonal surfaces* is intersected in its lines of curvature by the two series of surfaces to which it does not belong. (Dupin's *Développements de Géométrie*, p. 239, Paris 1813.) A system of confocal quadrics satisfies the above conditions, the surfaces of one system being ellipsoids, those of the second hyperboloids of one sheet, and those of the third hyperboloids of two sheets, whence a clear conception may be obtained of the lines of curvature on any surface of the second order. This conception, too, is rendered still clearer by another interesting theorem relative to quadrics, which was discovered by Mr. Michael Roberts (*Liouville's Journal*, vol. xi. p. 1); according to it the sum (or difference) of the geodesic distances from two umbilics of all points on the same line of curvature is invariable. Thus a line of curvature on an ellipsoid may be constructed mechanically in the same manner as an ellipse on a plane.

Curvature, Measure of. This expression, as applied to curves, has already been defined. [CURVATURE.] Gauss, however, in his classic *Disquisitiones generales circa Superficies Curvas*, has extended the definition to surfaces. In the first place, he defines the *total curvature* of any portion of a surface to be the area intercepted upon any unit-sphere by radii drawn parallel to the normals erected at the several points of the contour of the portion of the given surface under consideration. This premised, the measure of curvature at any

CURVATURE, SPHERICAL

point of a given surface is the ratio, to the surface-element around the point, of the total curvature of that element. The measure of curvature is easily shown to be equal to the reciprocal of the product of the two principal radii of curvature. It is consequently positive, negative, or zero, according as the point is elliptic, hyperbolic, or parabolic. [CURVATURE OF SURFACES.] Instructive information on this important subject, as well as references to original memoirs bearing thereon, will be found in Salmon's *Analytical Geometry of Three Dimensions*.

Curvature, Spherical. The term *spherical curvature*, as applied to a non-plane curve, denotes the curvature of any great circle of the osculating sphere. The *radius* and *centre* of *spherical curvature* are respectively the radius and centre of this sphere.

The curvature at an *umbilical* point of a surface is also said to be spherical, and a line every point of which is an umbilic on the surface is called a *line of spherical curvature*.

Curvature of Surfaces. The curvature of a surface at any point may be considered as determined by that of the plane sections through the point. Such sections, however, are of three kinds: 1. *Principal normal sections*, of which there are two, at right angles to each other, each containing the normal of the surface as well as a consecutive normal; 2. *Ordinary normal sections*, of which there are an infinite number, each containing the normal at the point but no other; and 3. *Oblique sections*, whose planes are inclined to the normal. The sections of the first kind are sections of maximum and minimum curvature. The curvature of every other section is determined from that of each of these sections of *principal curvature*. The methods of finding the *centres* and *radii* of *principal curvature* are given in every treatise on surfaces. The radius of curvature ρ of any normal section is given by the following important formula, due to Euler,

$$\frac{1}{\rho} = \frac{\cos^2 \alpha}{\rho_1} + \frac{\sin^2 \alpha}{\rho_2},$$

where ρ_1 and ρ_2 are the *principal radii of curvature*, and α the angle between the plane of normal section and that of the principal normal section whose radius of curvature is ρ_1 . Lastly, the radius of curvature ρ' of any *oblique section* is determined from that ρ of the normal section, whose plane contains the tangent of the oblique section, by means of the following formula,

$$\rho' = \rho \cos \theta,$$

where θ is the angle between the planes of normal and oblique section. The circles of curvature, therefore, of the normal and oblique sections are, respectively, a great and a small circle of one and the same sphere whose centre is in the normal. This is *Münier's Theorem*. In using the above formulæ it is necessary to bear in mind that the sign of a radius of curvature changes according as the convexity of the section is turned in one or the other direc-

CURVE

tion. When the principal radii of curvature have the same sign, so also have those of every normal section, and the curvature all round the point, which is called an *elliptic point*, is of the same character. When the principal radii are equal, their common value is obviously shared by the radius of curvature of every other section; the point of a surface at which this occurs is called an *umbilical* point, and the curvature there is said to be *spherical*. Every point of a sphere is an umbilic, and in an ellipsoid there are always four such points situated in the plane of the greatest and least axes. When the principal radii of curvature have opposite signs, every other normal section has a *numerically* greater radius of curvature, and there are two directions equally inclined to the principal normal sections for which the radius of curvature is infinite. A point on a surface where the curvature is of this kind is called a *hyperbolic* point, and the tangent plane at it cuts the surface in two straight lines, *inflectional tangents*. [INDICATRIX.] In two of the opposite angular spaces between these tangents, the surface is *above* the tangent plane, in the other two *below*. The shape of a saddle is a familiar illustration; another is the hyperboloid of one sheet through every point of which two straight lines can be applied to the surface. Lastly, when one of the radii of principal curvature is infinite, Euler's formula takes the form

$$\rho = \frac{\rho_2}{\sin^2 \alpha},$$

and the two inflexional tangents coincide; such a point on a surface is called a *parabolic* point. [INDICATRIX.] Every point of a cone or of a developable surface is of this kind.

Curvature, Total. As applied to the arc of a plane curve, this expression denotes the arc of a unit circle which is traced by the extremity of a radius constantly parallel to the normal of the curve, as the latter moves from one to the other extremity of the given arc.

The total curvature of any portion of a given surface has already been defined. [CURVATURE, MEASURE OF.]

Curve (Lat. *curvus*). In Geometry, is synonymous with *line*, and might, according to Euclid, be defined as that which has length, but neither breadth nor thickness. A curve may also be regarded as the locus of points whose positions are determined by some uniform law, usually expressed by one or more equations between the coordinates of those points. The term *curve*, involving as it does the conception of curvature or departure from a right line, is strictly speaking inapplicable to the latter; as synonymous with *line*, however, the term *curve* is also frequently applied to this simplest of all point-loci.

When the plane drawn through three points of a curve passes through all its other points, the curve is said to be *plane*. When this condition is not satisfied, the curve is called a *non-plane* or *twisted* one, and frequently also a *curve of double curvature*.

CURVE

Curves are further distinguished as *algebraic* or *transcendental*, according as the coordinates of their several points satisfy algebraic or transcendental equations.

A *plane curve* may not only be regarded as the locus of a movable point, but also as the envelope of a right line (tangent) variable in position. In both cases the curve may be represented by a homogeneous equation in three variables, the latter denoting in the first case the trilinear coordinates of any point, and in the second case the three-point coordinates of any tangent. The *degree* of the trilinear equation will indicate the number of points, real or imaginary, in which the curve is cut by any right line in its plane; the degree of the three-point equation, on the other hand, will give the number of tangents to the curve which pass through an arbitrarily chosen point. We are thus led to distinguish algebraic curves in two ways: a curve is said to be of the m^{th} order when it is intersected by every right line in m real or imaginary points, and of the n^{th} class when, through every point in its plane, pass n real or imaginary tangents. In the former case the curve is frequently called a *plane m -ic*, since its trilinear equation involves a quantic of the m^{th} order. [QUANTICS.]

A curve is further characterised by the possession of certain singularities, such as double and stationary points and tangents, the number of which depends upon the order and class of the curve, as was first shown by Plücker in his *System der analytischen Geometrie*, Berlin 1836. [SINGULARITIES OF CURVES AND SURFACES.]

Through

$$\frac{m(m+3)}{2}$$

given points it is always possible to draw a curve of the m^{th} order, and in general only one; for the general equation of the m^{th} contains

$$\frac{(m+1)(m+2)}{1 \cdot 2}$$

terms [COMBINATIONS], and therefore one less than this number of *independent* constants. For exceptional positions of the points, however, the curve so determined may not be a proper curve of the m^{th} order, but may consist of a system of curves of inferior order. For instance, a conic can be drawn through any five points, but when of these five, three are situated in a right line, the conic necessarily breaks up into a pair of right lines. And in general no *proper m -ic* can be drawn through

$$\frac{m(m+3)}{2}$$

points, of which more than

$$m(r-1)(r-2)$$

lie on a curve of inferior order r . Again, the positions of the

$$\frac{m(m+3)}{2}$$

given points may be such as not completely

to determine the curve of the m^{th} order, and whenever this happens an infinite number of curves may be drawn through the points, all of which will pass through

$$\frac{m(m-3)}{2}$$

other fixed points; namely, those which, with the given points, make up the m^2 intersection points of any two curves of the series. Thus through the nine intersection points of two cubics $U=0$ and $V=0$ will pass every cubic represented by the equation $U + \lambda V = 0$, where the parameter λ may have any value whatever. In fact, every m -ic through

$$\frac{m(m+3)}{2} - 1$$

of the m^2 intersections of two other m -ics will necessarily pass through all the rest. A system of curves of the m^{th} order passing through the same m^2 *fundamental points* is called a *pencil of curves*, of which the m^2 points constitute the *base*. Curves of higher order may often be advantageously generated by means of such pencils, just as conics are by means of pencils of lines. [CONIC SECTIONS.] On this subject the reader may consult an excellent memoir by De Jonquières in the *Mémoires présentés par divers Savants à l'Académie des Sciences*, tome xvi. Similar remarks apply to the determination of a curve of the n^{th} class by means of given lines which touch it.

Non-plane curves, considered as loci of points movable in space, are also divided into *orders*, the term *order* here indicating the number of points in which the curve is intersected by an arbitrary plane; hence, adopting the terminology of quantics, non-plane curves of the third, fourth, &c. orders are frequently called *cubics*, *quartics*, &c., the adjective *non-plane* or *twisted* being added when required. The complete intersection of two surfaces of the m^{th} and n^{th} orders respectively is obviously a curve of the mn^{th} order, which may be represented by the equations of these surfaces. It is not always possible, however, to find two surfaces whose intersection coincides precisely with a given curve; there is in general an embarrassing extraneous curve which, together with the given one, constitutes the complete intersection in question. A *twisted cubic*, for instance, cannot be the complete intersection of any two surfaces whatever, since the only factors of 3 are 1 and 3; it may be, however, and usually is, regarded as the *incomplete* intersection of two ruled surfaces of the second order (cones or hyperboloids) which have a common generator.

The tangents of a non-plane curve, or the lines joining pairs of consecutive points, lie on a developable surface called the *developable osculatrix*, each of its tangent planes being an osculating plane of the curve, i.e. a plane through three consecutive points. Every plane through a tangent touches the curve, of course, in the same point as the tangent itself, and the number of such *tangent planes* which can be

drawn through an arbitrary line in space, or, what is the same, the number of tangents which meet such a line, determines the *class* of the curve. By applying Plücker's equations connecting the singularities of plane curves to the plane projections of a twisted curve, as well as to the plane sections of its developable osculatrix, Mr. Cayley has succeeded in establishing the relations which exist between the singularities of any curve whatever. (*Cambridge and Dublin Mathematical Journal*, vol. v.) [SINGULARITIES.]

The properties of non-plane curves are of two kinds, *projective* and *non-projective*. The former do not involve the consideration of angles, whilst the latter have reference to the curvature, torsion, evolutes, &c., of the curve. One of the best treatises on this subject is that of St. Venant in the *Journal de l'Ecole Polytechnique*, cahier xxx. A more recent one has been published by P. Serret (*Théorie Nouvelle des Lignes à double Courbures*, Paris 1860), and by Schell (*Allgemeine Theorie der Curven doppelter Krümmung in rein Geometrische Darstellung*). The most important non-projective properties of curves, however, are given in all modern textbooks. Dr. Salmon's *Analytical Geometry of Three Dimensions* contains a very able exposition of their principal projective properties.

Curvograph. [ARCOGRAPH.]

Cuscutaceæ (Cuscuta, one of the genera). A very small natural order of Exogens, consisting of but one genus, inhabiting all the quarters of the globe, and related to *Convolvulaceæ*; but distinguished by the imbricate corolla which does not fall off after flowering, the spiral embryo, and the parasitical habit. Common dodder, a curious thread-like twining parasitical plant, found on heaths, belongs to the order.

Cushion Capital. A form of capital described by Whewell as being common in Romanesque work in England and on the Continent. It consists of large cubical masses projecting considerably over the shaft of the column, and rounded off at the lower corners.

Cusp (Lat. *cuspid*, *point*). In Architecture, a term applied to express the projecting points of the featherings, or foliations, in Gothic pannels, arches, or tracery.

Cusp. In Astronomy, the points or horns of the moon or one of the inferior planets.

Cusp. In Geometry, a *stationary point*. It may also be regarded as a double point at which the two tangents to the curve coincide, and constitute the *cuspidal tangent*. (As an illustration, see CUSPID.) There are two kinds of cusps, distinguished as *ceratoid* and *ramphoid*. The former is simply a stationary point at which the two branches of the curve lie on opposite sides of the cuspidal tangent; at the latter there is not only a stationary point, but likewise a stationary tangent, so that both branches of the curve lie on the same side of this tangent. A ramphoid cusp, therefore, constitutes a singularity of higher order than a ceratoid cusp.

Cusparia Bark. [ANGUSTURA.]

Cuspidal Edge. The curve enveloped by the rectilinear generators of a developable surface. The points in which such a curve is cut by any plane are all cusps of the section of the developable by that plane. The term *cuspidal edge*, which had its origin in this property, is synonymous with *edge of regression*, and in any envelope whatever denotes the locus of the intersections of successive characteristics. [CHARACTERISTIC OF AN ENVELOPE.]

When any plane section of a cone has a cusp, the generating line through the same is also called a *cuspidal edge of the cone*.

Cuspidal Tangent. [Cusp, in Geometry.]

Cuspidate (Lat. *cuspidatus*, from *cuspid*, a point). In Botany, a term used in describing the apex of a body, when it gradually tapers into a rigid point. It is also used sometimes to denote what is abruptly acuminate, as the leaflets of many Rubi.

Gustard Apple. A term applied in the West Indies to the fruit of the *Anona reticulata*.

Custom (Fr. *coutume*, Span. *costumbre*, from Lat. *consuetudo*). In Law, signifies generally a right or law not written, but established by long usage. To render a custom valid, it has been said that the following qualities are requisite: 1. Antiquity; i.e. that it shall have been used as far back as time of legal memory, that is, the first year of Richard I.; 2. Continuance without interruption; 3. Without dispute; 4. It must be reasonable; and 5. Certain;

6. Compulsory; 7. Customs must be consistent with each other. Customs may now be established by prescriptive use for a limited period. [PÆSCRIPTION.] Local customs are ascertainable by the verdict of a jury. An exception to this rule is to be found in the *Custom of the City of London*, which, if questioned, is established by certificate of the mayor and aldermen; with the exception of those customs from which the corporation itself claims a benefit. *Customs* (*coutumes*), in the law of France, were the laws relating both to movable and immovable property peculiar to different districts of the kingdom before the Revolution. Districts governed by customs were commonly termed *pays coutumiers*, in contradistinction to the remainder of the realm, which being under the civil law was termed *pays de droit Romain*. The *pays coutumiers* embraced all the north of France. The valid *coutumes* were estimated at 140 *general*, or comprehending districts, and 360 *local*, belonging to towns and places; but the enumeration was not exact. The *coutume de Paris* was the most important of all; and it was a generally recognised principle that when a case was unprovided for by local custom, that of Paris was to be applied in aid. Works containing the customary law of a particular district are styled *coutumiers*.

Customary Freehold. In Law, is a superior kind of copyhold; the tenant holding, as it is expressed, by copy of court roll, but not at the will of the lord. [COPYHOLD.]

Customs. A privilege, existing time out of mind (as is indicated by the name), by

CUSTOMS

which the king or his deputy took tolls on *imports*; analogous in their nature to the customary tolls of market towns, held and appropriated by the several lords of the manors in which the market was situate. Occasionally *export* duties were levied, especially on wool and hides, the staple products of this country during the middle ages; and these duties were also loosely called *customs*. In later times customs duties were known by the names *tonnage* and *poundage*: the former being apparently derived from the fact that the ancient custom on wine was a tun from before and behind the mast, if the vessel held twenty tuns of wine; and the latter from a primitive *ad valorem* duty, levied for instance in the year 1347, at the rate of sixpence in the pound. The city of London was exempted from the payment of customs by special charter, 1 John, June 17, 1199.

Tonnage and poundage were generally granted to the crown for life, the renewal of the grant being the earliest business of the first parliament summoned at the king's accession. Apparently (Parry's *Parliaments and Councils*) the first record of this practice is at the commencement of the reign of Henry VII., though according to *Parliamentary History* (vol. ii. p. 6) it had been the first formal act of every reign from the beginning of the fifteenth century. The first parliament of Charles I. granted tonnage and poundage for one year only, but the upper house rejected their bill. From this time, therefore, till the debates which followed on Charles's qualified acceptance of the Petition of Right, it was enacted at the sole will of the crown, and the king (June 29, 1628) prorogued the parliament on its remonstrance against the exaction. (Parry, pp. 325, 326.) Several merchants declined payment, and were distressed; among them Mr. Rolles, a member of the house. The question whether the exaction was legal was prominent among the debates during the remaining existence of this parliament, which was dissolved for this reason on March 10, 1629. What followed is matter of general English history. It is sufficient to say that tonnage was, *eo nomine*, abolished in 1696, and that the exigencies of the wars entered upon by William III. with Louis XIV., and the necessity for securing further credit by the appropriation of supplies, condemned the ancient and clumsy customs system. (Macpherson's *History of Commerce*, vol. ii. p. 676.) At the accession of William III. tonnage and poundage were estimated at 600,000*l*. (Davenant's *Works*, vol. i. p. 20.)

After the Revolution, provision was made for the payment of public debts, or rather precautions were taken against their repudiation. Hence they were secured on the proceeds of particular taxes, and among these taxes enlarged and modified customs duties were about the most common. If, as was sometimes the case, the produce of the tax exceeded the annual charge, the balance was paid over to the general purposes of the Exchequer, and this

separation of the produce of one duty from another, or, what was sometimes the case, the distinction drawn between the purpose of one part of the aggregate customs charge and another, was a serious hindrance to commerce. 'The many additions of customs to customs, excise to excise, and stamps to stamps, had altogether accumulated to such a mass of duties, that merchants and other individuals, finding it impossible to obtain a knowledge of the amount, or even the number, of the duties which they had to pay, were obliged to leave it entirely to those clerks of the custom-house or excise-office, who by constant practice had acquired a dexterity in it, to determine the amount of the duties payable. The separation of every branch of the duties in the office accounts, owing to each of them having been appropriated for paying the interest of some particular branch of the national debt, was also found productive of great perplexity.' (Macpherson's *History of Commerce*, vol. iv. p. 124.) The remedy for these inconveniences was the creation of the *Consolidated Fund*.

Originally all duties were leviable on the entrance of the vessel into port. The circumstances which led to an alteration of this rule, so very onerous to the public (because it often charged the duty long before consumption) and of no benefit to the government (because the receipt of the duty was just as advantageous if it occurred as near as possible to the act of consumption), will be adverted to under the head of *WAREHOUSES, BONDERS*.

In the infancy of finance, the incidence of a customs duty was very imperfectly understood, and the administration constantly interpreted an addition to a customs duty as identical with a tantamount increase of revenue. Experience, however, has shown that such an anticipation is liable to large corrections, though financiers have been very slow to comprehend and act upon the inductions of this experience. A high duty checks consumption to an extent larger even than an equivalent increase of price, because its effects are inevitable and permanent, while an increase of price may be corrected by diminution of general consumption and be only temporary. In other words, an increase of price has a tendency to correct itself by only affecting some; an increase of taxation has no such tendency, because it affects all. And, again, high duties are a powerful stimulus to the practice of smuggling. If a high duty leaves a large contingent rate of profit to parties who are disposed to evade the revenue laws (and there are, and perhaps always will be, many such persons), the practice of smuggling becomes general and frequently successful. Nor does it appear that any precautions will check this kind of trade, be the revenue officers ever so active and incorruptible. The smuggler plans his operations in secret, and is always in point of time considerably in advance of the detective. Napoleon's Berlin decree was inadequate to exclude English goods, even from those parts of the Continental markets which

CUSTOMS

were brought within the limits of his administration; and it is well known that during the existence of a Spanish tariff virtually prohibitive, the chief value of Gibraltar consisted in its being a smuggling dépot. Again, as is well known, an effective blockade is all but an impossibility, for when the profits of a successful venture are very great, the risks may be great also, without checking the attempts to elude the blockade intended to prevent the importation of commodities.

Up to the tariff reforms of Sir Robert Peel in 1845, the number of commodities liable to customs was enormous, almost every conceivable article of foreign produce being charged with import duties, some of them being even on raw materials. But since that time the success of Peel's legislation has been so marked as to form a precedent for the simplification of the customs system, so that at present the following articles only are subject to duty: chicory, cocoa and coffee, corn of all sorts with flour and meal, certain kinds of highly saccharine fruits and confectionery, plate of foreign manufacture, pepper, spirits, sugar, tea, tobacco, vinegar, wine, and wood.

With two exceptions, these customs are levied on articles, to a greater or less extent, of voluntary use. The exceptions are corn and timber. As to a very great degree the fiscal system of this country is characterised by its adding to the price of articles in voluntary use, by the levy of a tax upon the use of such commodities, the system of customs duties at present in force is, on the whole, a well-balanced and satisfactory arrangement. It is understood that these duties are collected merely as a tax on expenditure, not as a protective scheme (with some few unimportant exceptions), still less as a sumptuary check. It may be disputed on abstract grounds, whether customs duties are a desirable source of revenue. But if they are, the principle on which they are at present levied is, with two exceptions, just and judicious.

The exceptions are corn and timber. For every reason, it would be matter of the greatest prudence to abolish all duty on corn. Dependent as the people of this country are, and to secure their industrial precedence among nations must be, upon the importation of food, it would be in the highest degree desirable that this country should be as effectually the entrepôt of grain as it is of the precious metals. The interposition even of a duty of one shilling a quarter, is as certain to check the accumulation of foreign corn in any country, as the impost of sixpence on the ounce of gold, or on the pound of silver, would divert the accumulation of these metals to other and wiser communities.

The case of the customs on timber is analogous to that of duties on corn, though not perhaps so strong. It is manifest that house-room is a necessary of life, and that any pressure of taxation which falls on absolute necessities is, both on rational and economical grounds, a public injury. The evil, too, is ex-

CUTTER.

aggerated when, as is the case with all necessities of life, the proportion of expenditure devoted to their acquisition is in a ratio increasing with the poverty of the purchaser. And when we consider the effect of the tax on timber employed for mills, manufactories, and warehouses, we find that all the evils which attend taxes on raw material, that is on commodities not available for consumption except at some protracted period, apply to such imports. The burden and loss of the tax to those who pay it, either directly or indirectly, is considerably greater than the amount received by the Exchequer. An annual tax, for instance, on each spindle employed in a spinning mill, if proportioned to the charge contained in the outlay for the timber employed in constructing the mill, would be much less onerous to the public at large than the tax paid at once for the raw material of the structure; and this for the reason that taxes levied on raw materials multiply in the process of use and manufacture, till they come to present an increased charge in the product, frequently many times in excess of the tax originally imposed. [DUTY; EXCISE; TARIFF; TAXATION.]

Custos Rotulorum. The first civil officer of a county is so called, as being keeper of the rolls or records of the sessions of the peace. The lord-lieutenant is always appointed to the office, although it is, in itself, quite distinct from the lieutenancy.

Cut-in, or In-cut, Notes. In Printing, side-notes which are not arranged in the front margin down the side of the page, but are inserted in the text by shortening the lines, as if a piece of the text were cut out, and the note put into the vacant space.

Cuticle (Lat. cuticula, dim. of cutis, *skin*). In Anatomy, the scarf skin. The exterior membranous covering of the body. In its chemical characters it resembles nail, quill, &c., and has the properties of a condensed form of albumen.

CUTICLE. In Botany, the thin vesicular membrane that covers the external surface of vegetables, and adheres firmly to the cellular substance beneath it. It acts in plants as a means of preventing a too rapid perspiration, and is furnished with respiratory openings called *stomata*.

Cutlass. A broadsword, about three feet long, and of great weight, used by sailors in hand-to-hand encounters.

Cutlery (Fr. *coutellerie*, from *conteau* = Lat. *cultellus*, a *knife*). A term used to designate all kinds of sharp and cutting instruments made of iron or steel, as knives, forks, scissors, razors, &c. The principal seat of the manufacture of British cutlery is Sheffield; and the articles made there are held in the highest estimation in all parts of the world. [HARDWARE.]

Cutter. A vessel with one mast and a bowsprit, of considerable breadth in proportion to her length. The distinction between a cutter and other vessels of one mast, called *ships*, is that in the cutter the jib has no stay to support it.

Cuttle 'sh. [SEPIA.]

CUTWATER

Cutwater. The apex of the wedge formed by the bow of a ship or boat. It is an extension forwards of the beam at which the planking meets which covers the two sides of the ship. The cutwater helps to cleave the water in which the ship is making her voyage.

Cyanetide. A white solid, resulting from a spontaneous molecular rearrangement of hydrated cyanic acid.

Cyaneturic Acid. An organic acid formed on heating mellonide of potassium. When isolated, it is a white semicrystalline solid.

Cyanamide. White crystals formed on evaporating an ethereal solution of ammonia, into which chloride of cyanogen has been passed. By substituting other ammonias for the ordinary, corresponding cyanamides are formed.

Cyanethine. A crystalline polymeride of cyanide of ethyl, from which it is formed by the action of potassium.

Cyanic Acid. An intensely corrosive liquid, produced when cyanuric acid is distilled. *Cyanates* are formed by oxidising cyanides.

Cyanic Ether. A volatile liquid composed of cyanic acid and oxide of ethyl.

Cyanides, Cyanurets. Compounds of cyanogen. Prussian blue is a cyanide of iron.

Cyanilic Acid. A crystalline body closely resembling cyanuric acid. Formed on boiling hydromellon with nitric acid.

Cyaniline. A direct compound of cyanogen and aniline. It is somewhat unstable, but crystallises and forms salts with acids.

Cyanin. The colouring matter of red and blue flowers. Alcohol extracts it from the petals of the violet or iris. Alkalies turn it blue and green, acids redden it.

Cyanite (Gr. *κυανός*, blue). A massive and crystallised mineral. It has a pearly lustre, is translucent, and of various shades of blue. It is a silicate of alumina, with a trace of oxide of iron. Only found in primitive rocks.

Cyanogen (Gr. *κυανός*; because it is an essential ingredient of Prussian blue). Cyanogen is a gas of a strong and peculiar odour, resembling that of rubbed peach leaves; it is obtained by heating *cyanide of mercury*. Under a pressure of between 3 and 4 atmospheres it becomes a limpid liquid. It extinguishes a taper, is highly poisonous and unrespirable, and burns in contact of air with a rich purple flame. Water absorbs between 4 and 5 times its volume of the gas. It is composed of carbon and nitrogen in the proportions of 12 carbon + 14 nitrogen = 26 cyanogen; it is therefore a bicarburet of nitrogen. Mixed with oxygen it explodes by the electric spark, and is resolved into carbonic acid and nitrogen gases. It combines with hydrogen to produce the *hydrocyanic* or prussic acid. It forms with the metals *cyanurets* or *cyanides*.

Cyanolite (Gr. *κυανός*, and *λίθος*, stone). An iridescent bluish silicate of lime, forming the central part of a nodule found in crystalline trap-rock in the bay of Fundy. [CENTRAL-LASSITE.]

CYOLANTHÆÆ

Cyanometer (Gr. *κυανός*, and *μέτρον*, measure). An instrument contrived by Saussure for determining the deepness of the tint of the atmosphere. A circular band of thick paper or pasteboard is divided into fifty-one parts, each of which is painted with a different shade of blue, decreasing gradually from the deepest blue formed by a mixture of black, to the lightest formed by a mixture of white. The coloured zone is held in the hand of the observer, who notices the particular tint which corresponds to the colour of the sky. The number of this tint, reckoned from the lightest shade, marks the intensity at the time of observation.

Cyanosis (Gr. *κυανωσις*). In Medicine, the *blue disease*. A blueness of the body occasionally arises from malformation of the heart. The whole of the body, and especially its exposed parts, often acquire a blue or lead colour, in consequence of the administration of nitrate of silver.

Cyanosite (Gr. *κυανός*). Native sulphate of copper. This salt is rarely found in distinct crystals, but generally in stalactitic and other forms in the fissures and hollows of old mines, or dissolved in the waters which issue from them. In the latter case metallic copper is frequently procured by placing fragments of scrap-iron in the water, by which sulphate of iron is formed and metallic copper precipitated.

Cyanurets. [CYANIDES.]

Cyanuric Acid. A crystallisable acid, obtained by decomposing urea by heat.

Cybele (Gr. *Κυβέλη* or *Κυβήθη*). In Mythology, is supposed to have been originally the Phrygian goddess of the earth. When her worship was introduced among the Greeks, they identified her with Rhea, as did the Latins with their Ops. Her rites, like those of the Asiatic deities, in general were celebrated with great excitement; her priests, who were called Galli, Corybantes, Curetes, &c., running about with howlings and clashing of cymbals.

Cycadaceæ (Cycas, one of the genera). In Botany, a very small natural order of arborescent Gymnosperms, inhabiting the tropics of Asia and America. They are very nearly related to *Conifera*. They are known by their simple stems, pinnate leaves, and antheriferous cones. The vessels contained in the wood of both orders are of the same structure. The only remarkable quality in the *Cycadaceæ* is the production of a kind of sago by the soft centre of *Cycas circinalis*.

Cycadeoidea. A name given by Buckland to a genus of fossil dycotyledonous plants: the genus *Mantellia* of Brongniart.

Cycadites. A genus of dicotyledonous fossil plants.

Cyclamin. [ARTHAMITIN.]

Cyclanthææ (Cyclanthus, one of the genera). In Botany, a section of *Pandanaçæ* inhabiting the tropics of the western hemisphere, and distinguished from *Pandana* by their plaited, flabellate, or pinnate leaves and spiral scaly flowers.

CYCLAS

Cyclas (Gr. κύκλος, a circle). A genus of fresh-water air-breathing Gastropods or snails so named on account of the more or less rounded circumference of the shell in all the species. Of these the following are native of Britain: the river cycle (*Cyclas rivicola*, Leach), the largest species of which is not uncommon in the smaller streams communicating with the Thames; the horny cycle (*C. cornua*, Lam.), common in ditches near Battersea cupped cycle (*Cyclas calyculata*, Drap.); lake cycle (*Cyclas lacustris*, Drap.).

CYCLAS. An article of dress worn both with and without defensive armour, which came into fashion about the reigns of Edward II. and Edward III. in England. It was a mantle or surcoat without sleeves, of silk, cloth, &c., reaching to the knees before and to the calves of the legs behind. It was succeeded by the jupon or gyppon, a shorter kind of surcoat.

Cycle (Gr. κύκλος). The revolution of a certain period of time which finishes and recommences perpetually. Cycles were invented for the purposes of chronology, and for marking the intervals in which two or more periods, of unequal length, are each completed a certain number of times, so that both begin again exactly in the same circumstances as at first. The cycles used in chronology are three: the cycle of the sun, the cycle of the moon or Metonic cycle, and the cycle of indiction.

The cycle of the sun, or solar cycle, is a period of time after which the same days of the week recur on the same days of the year. If the number of days in the year were always the same, this cycle could only contain seven years; but the order is interrupted by the intercalations. In the Julian calendar the intercalary day returns every fourth year, and the cycle consequently contains $4 \times 7 = 28$ years; after which period the Dominical letters return in the same order, or the first day of the year and of every month falls again on the same day of the week. The origin of this cycle is unknown; it is supposed to have been invented about the time of the council of Nice (325); but the first year of the first cycle is placed by chronologists nine years before the commencement of the Christian era. Hence the year of the cycle corresponding to any given year in the Julian calendar is found by the following rule: *Add nine to the date, and divide the sum by twenty-eight; the quotient is the number of cycles elapsed, and the remainder is the year of the cycle.* Should there be no remainder, the proposed year is the twenty-eighth, or last of the cycle. In the reformed calendar this rule can only apply from century to century; for the order is interrupted by the omission of the intercalary day every hundredth year, and is not restored till the end of four hundred years. [DOMINICAL LETTER.]

The cycle of the moon is a period of nineteen solar years, after which the new and full moons fall on the same days of the year as they did nineteen years before. This cycle was invented by Meton, an Athenian astro-

CYCLIC CHORUS

nomer, and the chronological period which he founded on it is celebrated in history under the name of the *Metonic cycle*. The Metonic cycle contained exactly 6,940 days, which exceeds the true length of nineteen solar years by nine and a half hours nearly. On the other hand, it exceeds the length of 235 lunations, or synodic revolutions of the moon, by seven hours and a half only. The framers of the ecclesiastical calendar, in adopting this period, altered the distribution of the lunar months, in order to accommodate them to the Julian intercalation; and the effect of the alteration was that every three periods of 6,940 days was followed by one of 6,939. The mean length of the cycle was therefore 6,939½ days, which agrees exactly with nineteen Julian years. A table, therefore, showing the days of the new and full moons for nineteen years, would serve to show the days of these phenomena for any year whatever when its number in the cycle is known. The number of the year in the cycle is called the *golden number*; either because it was so termed by the Greeks, who, on account of its utility, ordered it to be inscribed in letters of gold in their temples, or more probably because it was usual to distinguish it by red letters in the calendar. The cycle is supposed to commence with the year in which the new moon falls on the 1st of January. This happened in the year preceding the commencement of our era; hence to find the number of any year in the lunar cycle, or the golden number of that year, we have this rule: *Add one to the date, and divide by nineteen; the quotient is the number of cycles elapsed, and the remainder is the year of the cycle.* Should there be no remainder, the proposed year is the last or nineteenth of the cycle.

Cycle of indictions, or Roman indiction, a period of fifteen years; not astronomical, like the two former, but entirely arbitrary. Its origin and the purpose for which it was established are alike uncertain; but it is conjectured that it was introduced by Constantine the Great, about the year 312 of the common era, and had reference to certain judicial acts that took place under the Greek emperors at stated intervals of fifteen years. In chronological reckoning, it is considered as having commenced on the 1st of January of the year 313. By extending it backwards to the beginning of the era, it will be found that the first year of the era corresponded with the fourth of the cycle. In order, therefore, to find the number of any year in the cycle of indiction, we have this rule: *Add three to the date; divide the sum by fifteen, and the remainder is the year of indiction.* [CALENDAR.]

Cyclic Chorus. The chorus which performed the songs and dances of the Dithyrambic Odes at Athens. They derived their name from the circumstance of their dancing round the altar of Dionysus (Bacchus) in a circle (κύκλος), and were thus distinguished from the square (τετραγώνος) choruses of tragedy.

CYCLIC PLANES OF A CONE

Cyclic Planes of a Cone. The two planes, through one of the axes, which are parallel to the planes of circular section of the cone. The equation of a cone being thrown into the form

$$x^2 + y^2 + z^2 = \lambda L M,$$

$L=0$ and $M=0$ will obviously be the equations of its cyclic planes, and by attributing to the parameter λ all possible values the above equation will represent a system of conyclic cones. [CONOTICUS QUADRICS.] The perpendiculars to the cyclic planes through the vertex are the focal lines of the reciprocal cone. [FOCAL LINES.] A sphere around the vertex of the cone is cut by the latter, its cyclic planes, and its focal lines respectively in a *sphero-conic*, its *cyclic arcs*, and its *foci*, and thus the reciprocal properties of cyclic planes and focal lines give rise to properties of sphero-conics which are in many respects precisely similar to those of plane conics. [SPHERO-CONICS.]

Cyclic Poets. The vast number of poems, which treated of the mythological and heroic ages of Greece, rendered some arrangement in the order of reading them absolutely necessary. Thus, besides the *Iliad* and *Odyssey* of Homer, there were five other epic poems relating to the legend of Troy alone, two giving the adventures of Hercules, with many others which are now known only by name. These poems were arranged at Alexandria, in the second century A. C., not according to merit, but simply by the order of the events which they professed to narrate; and the whole collection received the name of the Epic Cycle. This cycle comprised the Homeric poems as well as all others; but, inasmuch as the former were generally spoken of by themselves, the phrase *cyclic poet* came gradually to express inferiority. (Grote's *History of Greece*, part i. ch. xxi.)

Cyclical Permutation. [PERMUTATIONS.]

Cyclifying Line, Plane and Surface.

The developable surface which contains a given non-plane curve, and which on being unfolded transforms that curve into a circular arc of a given radius, is called the *cyclifying surface* corresponding to that radius. Its tangent planes are the *cyclifying planes* of the curve, and its generators the *cyclifying lines*. The theory of cyclifying surfaces possesses considerable interest, being obviously a generalisation of that of the rectifying surface, which latter in fact is a cyclifying surface corresponding to the radius infinity. The developable osculatrix of a common helix, or more generally of any curve with constant radius of curvature, is clearly a cyclifying surface. The subject has been investigated to some extent by Molins. (Liouville's *Journal*, s. 2, tom. i.; and Schell, *Allgemeine Theorie der Curven doppelter Krümmung*, Leipzig 1859.)

Cyclobranchians, Cyclobranchiata (Gr. *κύκλος*, and *βράγχια*, gills). The name of an order of hermaphrodite Gastropodous Molluscs, including those in which the branchiae consist of little tufts or pyramids attached in a

CYCLOID

circular arrangement to the inner surface of the margin of the mantle.

Cyclograph. [ARCOGRAPH.]

Cycloid or **Trochoid** (Gr. *κύκλος*, and *τροχός*, like a circle or wheel). In Geometry, one of the transcendental curves, described by a point P in the circumference of a circle which rolls along an extended straight line A B until it has completed a revolution. Some of the properties of the curve are obvious from this definition. The line A B, which is called the *base* of the cycloid, is equal to the circumference $2\pi r$ of the generating circle; and CD, which is the axis of the cycloid, is equal to the diameter $2r$. In any position EPF of the generating circle,

$$AE = \text{arc } EP = r\phi,$$

$$AQ = x = AE - PR = r(\phi - \sin \phi),$$

$$PQ = y = r(1 - \cos \phi).$$

It is also easy to prove that the whole length of the cycloid ADB is equal to four times CD, and the whole area or space between the curve and its base three times that of the generating circle. A portion of the curve DP, counted from its summit, is double of FP, the supplemental chord of the arc EP; and FP is also a tangent to the cycloid at P. The curve has many other remarkable properties which have been discovered by more recondite investigations. Its *involute*, or the curve formed by unfolding a thread or flexible line APD, fixed at A, is a semicycloid equal and similar to APD. If a heavy body slide, without friction, down the arc of an inverted cycloid, it will arrive at the lowest point D in precisely the same time, no matter whether it start from P, P' or A. This property of the cycloid is termed *isochronism*. If a body is to descend by the force of gravity from a point A to another point D not in the same vertical line, it will accomplish the passage in a less time by describing the cycloid APD than by moving in the straight line AD, or in any other path whatever. [BRACHISTOCURVE.]

The cycloid may be made to assume an endless variety of forms by placing the tracing point not in the circumference of the generating circle, but without or within it, though still in the same plane. When the tracing point is without the circle, the curve has its base shortened, and is called the *curtate* or *contracted cycloid*. If the point is within the circumference, the curve is called the *prolate* or *inflected cycloid*.

Few curves have afforded finer scope for the exercise of modern geometry than the cycloid. Its properties successively engaged the attention of Roberval, Fermat, Descartes, Pascal, Slusius, Wren, and Wallis. Huygens rectified the curve so early as 1657; and having afterwards discovered its isochronism, he applied these discoveries to the improvement of the pendulum, and showed how a perfectly syn-

CYCLOID, COMPANION TO THE

chronous vibration could be procured, tically at least, by causing a flexible rod to vibrate between cycloidal cheeks. Its property of being the line of swiftest descent was discovered by John Bernoulli in 1697.

Cycloid, Companion to the. This name was given by Roberval (*Mémoires de l'Académie Royale des Sciences*, tome iv. 1730) to a certain curve, intimately connected with the cycloid, by means of whose properties he succeeded, in 1634, in solving the problem of the quadrature of the cycloid which had been proposed to him six years previously by Mersenne. The curve in question may be conceived to be generated by a point M [CYCLOID] which always remains vertically over the point of contact E of the rolling circle and its base AB, and in the same horizontal line as the describing point P. The companion to the cycloid obviously bisects the rectangle on AB and CD, so that its area is equal to twice that of the rolling circle. On the other hand it can be easily shown that the area of the space between the cycloid and its companion is precisely equal to that of the rolling circle, so that the area of the cycloid itself is three times that of the circle.

Cycloides (Gr. κυκλοειδής, *circular*). A name given by Agassiz to one of his orders of Fishes, the species composing which have scales composed of simple layers with smooth margins, but often ornamented on their exterior surface with different figures impressed upon all the layers, which are of horn or bone without enamel. The scales of the lateral line, instead of being flat, are funnel-shaped; the contracted part applied against the disc of the scale forms the tube by which the mucus exudes which covers the fish. The families included in the *Cycloid* order are: *Labroides*, *Mugil*, *Atherini*, *Scomberoides*, *Gadnides*, *Gobioides*, *Muraenoides*, *Lucioides*, *Salmonoides*, *Clupeoides*, and *Cyprinoides*.

Cyclones (Gr. κυκλός). Rotatory storms or whirlwinds, occurring in the tropical seas of China, the West Indies, and round Mauritius, but never on the equator. Their diameter is generally about 200 or 300 miles, but sometimes exceeds even 500. The centre of the vortex (which is always calm) travels at a rate varying from two to thirty miles an hour. These storms are preceded by a singular stillness of atmosphere, and a rapid fall of the barometer. They are perhaps the most destructive of all storms.

Cyclopædia or Encyclopædia (Gr. ἐγκυκλοπαιδεία, from the words ἐγκύκλιος παιδεία, the circle of arts and sciences gone through in Greek education). A work containing definitions or accounts of the principal subjects in one or all departments of learning, art, or science. Its arrangement may be either according to divisions into the various sciences, &c., or the subjects may be arranged and treated in alphabetical order. The *Encyclopédie Française*, or *Dictionnaire Encyclopédique*, and the *Encyclopædia Britannica*, have been the most celebrated works of this species; but the earliest

CYGNUS

was to be the *Lexicon Technicum* of Harris, published in 1706. The great French work, the *Encyclopédie Méthodique*, consists, not of one, but of a series of encyclopædias or dictionaries. [DICTIONARY; ENCYCLOPÆDIA.]

Cyclopean. A term applied to certain huge structures the remains of which are found in many parts of Greece, Italy, and Asia Minor, the architecture of which was totally different from that which prevailed in the historical ages. The epithet originated in the Grecian tradition that assigned these buildings to the gigantic strength of the Cyclopes. They are distinguished by the irregular character of the masonry and the large dimensions of the stones, which are laid without any mortar.

Cyclopeite. [BREISLAKITE.]

Cyclopes (Gr. κύκλωψ). In Mythology, a race of gigantic beings represented by the later poets as dwelling in Sicily, where they assisted Hephestus or Vulcan in forging the thunderbolts of Jupiter. They had only one eye, round, and situated in the centre of the forehead. The most celebrated among them was Polyphemus, a son of Poseidon, the god of the sea. The ninth book of the *Odyssey* relates his discomfiture by Odysseus (Ulysses).

Cyclopit. A hydrated silicate of alumina and lime with minor proportions of peroxide of iron, magnesia, soda and potash. It occurs in the dolerite of the Cyclopean Islands in small, white and transparent crystals with a vitreous lustre.

Cyclosis (Gr. κύκλωσις). A term applied by Schultz to that general motion of latex or the vital fluids of plants, which passes through vessels of a peculiar kind, and which is diffused through the system of plants without interruption; in distinction to *rotation*, or the movement of fluids in separate cells, as in *Chara*, *Vallisneria*, &c. According to this physiologist, the phenomenon of cyclosis is confined to the highest forms of vegetation, while that of rotation is characteristic of the more imperfect orders of plants.

Cyclostoma (Gr. κυκλός, and στόμα, *a mouth*). A genus of air-breathing Gastropods or snails; so called on account of the circular form of the aperture of the shell. *Cyclostoma elegans* and *Cyclostoma productum* are both natives of England.

Cyclostomes, Cyclostoma. A tribe of cartilaginous fishes, including those in which the mouth is surrounded by a circular lip, forming a large sucker, as in the lamprey.

Cydonia (from Cydon, in Candia, its native place). The Quince, *C. vulgaris*, is the principal member of this genus of *Pomaceæ*, which is distinguished from *Pyrus* by the leafy calyx lobes, and the many-seeded cells of its fruit. The Quince is a well-known hardy deciduous tree, cultivated for its austere fruit, which, however, is turned to good account by cooks and confectioners.

Cygnus (Lat. *the swan*). In Astronomy, one of the old constellations in the northern hemisphere.

CYGNUS. In Ornithology. [SWAN.]

CYLINDER

Cylinder (Gr. *κύλινδρος*, from *κύλινδρον*, roll). In Architecture, a system of executing foundations has been lately introduced, in which cylinders of iron are employed, and the interior of the cylinder is then excavated to the depth that may be required and the space filled in with concrete. The descent of the cylinder may be effected in various ways, either by pneumatical pressure, or by direct impact after the ground in the interior has been removed. The bridges at Rochester, Saltash, Strasburg, Theiss &c. were founded in this manner, which is becoming very fashionable amongst our engineers.

CYLINDER. In Geometry, a solid which may be conceived to be formed by the revolution of a rectangular parallelogram about one of its sides. The surface of a cylinder, not including the two ends, is equal to the rectangle formed by multiplying the circumference of its base into its altitude; and the solid content is equal to its altitude multiplied into the area of its base. A sphere, and the cylinder circumscribed to it, have a remarkably simple relation to each other, first discovered by Archimedes, their volumes being as 2 : 3.

The above definition of a cylinder is that given by Euclid; the term is now used, however, to denote, generally, the *surface* generated by a right line moving parallel to itself. Cylinders are distinguished according to the nature of their plane sections or, like all other surfaces, according to their *orders*. The plane sections of cylinders of the second order may be any of the conic sections: we have thus *elliptic*, *hyperbolic* and *parabolic* cylinders amongst quadric surfaces. If the section perpendicular to a generator be a circle, the cylinder is said to be a *right cylinder*, and is the one defined by Euclid. If such a section be an ellipse, there will always be two others, equally inclined to the generators, which will be circular [CYCLIC PLANES], and, considering either of these cyclic planes as the base, the cylinder is said to be *oblique*. All cylinders are cut by parallel planes in equal and similar curves.

Cylindrical Boiler. A boiler made entirely in the shape of a cylinder is known under this name. It is simple in its construction, and admits of greater resistance to the lateral action of the causes of displacement than most others; but it is the most expensive on the score of the fuel needed to raise the heat. In fact, the fire is made beneath the cylinder, and has therefore to boil the water mainly by the passage of the heat through the body it contains.

Cylindro-conical. In Gunnery, a term applied to a shot the body of which is cylindrical, and the head conical in form.

CYLINDRO-CONOIDAL SHOT have conoidal heads: of this form are the service shot in use with Armstrong rifled guns.

CYLINDRO-OGIVAL SHOT have ogival heads. This form of head has been found, by recent experiments, to offer the least resistance to the atmosphere, and consequently to lose less velocity during flight than any other.

CYCNICS

Cylindroid (Gr. *κυλινδροειδής*). A solid which differs from a cylinder in having ellipses instead of circles for its ends or bases. The term is now rarely used.

Cyma (Gr. *κύμα*, a wave). In Architecture, a name applied to a moulding deriving its name from its contour resembling that of a wave, being hollow in its upper part and swelling below. Of this moulding there are two sorts; the *cyma recta*, just described, and the *cyma reversa*, whose upper part swells, whilst the lower is hollow. By the workmen these are called *ogees*.

Cymbals (Gr. *κύμβαλον*, from *κύμβος*, a hollow). Brass musical instruments of percussion, played in pairs by striking one against the other. They are circular, about six or eight inches diameter, attached to leather mountings, by which they are held. Cymbals are of great antiquity. They were employed by the Greeks in the festivals of Cybele and Bacchus.

Cymbium (Lat.; Gr. *κυμβιον*, a small cup). In Natural History, a name given by many writers to a kind of sea-shell, commonly called the *gondola*. It belongs to the family *Volutidae*. The *Cymbium melo* often attains a gigantic size.

Cyme (Gr. *κύμα*, a sprout). In Botany, a form of inflorescence consisting of a solitary flower seated in the axils of dichotomous ramifications, as in *Sambucus*. This term is also sometimes improperly used, in place of *coma*, to express the head of a forest-tree.

Cymol. A hydrocarbon, contained in the volatile oil of cumin = $C_{10}H_{16}$.

Cymophane (Gr. *κύμα*, a wave, and *φαίνωμαι*, appear). The name given to those semi-transparent varieties of Chrysoberyl which display a peculiar milky or opalescent appearance. [CHRYSOBERYL.]

Cynapia, Cynapine. An alkaloid said to exist in Fool's Parsley (*Æthusa Cynapium*).

Cynaraceæ (Cynara, one of the genera).

Botany, one of the divisions of the great group of *Compositæ*, admitted by Jussieu. It contains the thistle, the artichoke, and similar plants, which have their capitula surrounded by a hard spiny or lacerated involucre, and long equal tubular florets with an inflated limb. They are also called *Cynarocephalæ*.

Cynarrhodium. In Botany, a fruit with distinct ovaries, and hard indehiscent pericarps enclosed within the fleshy tube of the calyx, as in *Rosa*.

Cynics. A sect of philosophers among the Greeks, so called from their snarling humour, and their disregard of the conventional usages of society; the name being derived from *κύων*, a dog. It is difficult to give any satisfactory account of the tenets of this sect, as during all the period of its existence it was in a state of constant fluctuation. Its professed aim was to inculcate the love of rigid virtue and a contempt of pleasure. On this point the testimony of Horace—himself a zealous adherent of the school of Aristippus, the very opposite of the

CYNIPS

cynical sect—even were there no other, must be held to be conclusive; and, according to his opinion, the aim of the cynical philosophy was to induce every man to become

Virtutis veræ custos, rigidusque satelles.

This sect, to which Diogenes belonged, was founded by Antisthenes, a disciple of Socrates, who sought to imitate his master in disregard of outward splendour and contempt of riches; but his indifference to these things soon degenerated into an ostentatious display of poverty.

Cynips. A Linnæan genus of Hymenopterous insects, belonging to that section which has not a poisonous sting. The ova of this genus are deposited in living trees, and the irritation excited by their presence gives rise to the formation of the excrescences called *galls*.

Cynodin. A crystalline matter found in Dog-grass (*Cynodon dactylon*).

Cynomoriaceæ (Cynomorium, one of the genera). In Botany, a group of Rhizantha now included in *Balanophoraceæ*. One species, *Cynomorium coccineum*, is a native of Malta, and was formerly supposed to possess great medicinal powers as an astringent: it figures in old official catalogues under the name of *Fungus melitensis*.

Cynosarges (Gr. *κυνδαργες*). A sort of academy in the suburbs of Athens, situated near the Lyceum: so called from the mythological story of a white dog (*κύων ἀργού*), which, when Dionus was sacrificing to Hercules, carried off part of the victim. Besides possessing several temples erected in honour of Hercules, Alcmena, and other gods, it was chiefly famed for its gymnasium, in which foreigners or citizens of half-blood used to perform their exercises; and as being the place where Antisthenes instituted the sect of the cynics, and taught his opinions.

Cynosure (Gr. *κυνόσουρα*). Literally, the tail of a dog, applied by some philosophers to the constellation Ursa Minor: whence it has been borrowed by the language of poetry, in which it signifies 'a point of attraction.'

Where perhaps some beauty lies,

The cynosure of neighbouring eyes.—*L'Allegro*, 79.

Cynthius and Cynthia. In Mythology, surnames given by the ancient poets to Apollo and Artemis; from Cynthus, a mountain of the island of Delos, on which they are said to have been born.

Cynurenic Acid. A crystalline acid found in the urine of the dog. It differs from uric acid in being soluble in hydrochloric acid.

Cyperaceæ (Cyperus, one of the genera). A natural order of Endogens, inhabiting the marshes, ditches, streams, &c. of all countries. They closely resemble *Graminaceæ*; but are distinguished from them by the stems being solid and angular, not round and fistular, and by there being no diaphragms at the articulations. They approach *Juncaceæ* and *Rustiacæ*, but are known at once by the sheaths of their leaves not being split. Their sensible properties are unimportant. *Carex arcuraria* affords one of the European substitutes for sarsaparilla.

CYRENIANS

Cyphellæ. A term used in describing lichens, to denote pale tubercle-like spots on the under surface of the thallus.

Cypher. In Diplomatic affairs, 'an occult manner of writing, legible to those only who possess the key or secret.' This art, in a variety of forms, has been more or less practised in every civilised country; and has been cultivated by the moderns in particular to such a degree as to have acquired the importance of a distinct science, under the names *Cryptography*, *Polygraphy*, *Stenography*, &c.

Cyphenism (Gr. *κυφηνισμός*, from *κύβηρ*, a piece of bent wood). A species of punishment, which consisted in beaming the criminal with honey, and then exposing him to insects. This punishment was carried into effect in various ways, but chiefly by fastening the sufferer to a stake, or extending him on the ground with his arms pinioned.

Cyprea. The name of a Linnæan genus of the *Vermes Testacea*, characterised by a subovate smooth shell, with a linear aperture extending from one end of the shell to the other, and transversely furrowed or dentated in the mature state. The genus is retained without subdivision, and forms part of the *Buccinoid* family of the Pectinibranchiate order of Gastropods of the system of Cuvier.

This genus is remarkable for the difference of form which exists in the young and old states of the shell: in the former the lip is thin, and the aperture wide, but the mantle is progressively developed until its lobes extend over the columella on the one side and the lip on the opposite side of the aperture, covering them with successive layers of nacreous shell, and at length diminishing the aperture to a narrow linear form. [COWRY.]

Cypriæ. A blue variety of Idocrase, found near Tellmarken in Norway. The colour is supposed to be caused by copper.

Cyprinus (Lat.). A Linnæan genus of abdominal fishes, now the type of a family of Malacopterygians in the system of Cuvier, and of Cycloid fishes in the system of Agassiz; including the genus *Cyprinus* proper, or carps; *Barbus*, or barbels; *Gobio*, or gudgeons; *Tinca*, tenches; *Abrama*, breams; *Leuciscus*, minnows; *Cirrhinus*; *Labeo*; *Catostomus*; and *Gonorhynchus*.

Cypselæ (Gr. *κυψέλη*, a chest). In Botany, a one-seeded, one-celled, indehiscent fruit, with the integuments of the seed not cohering with the endocarp: in the ovarium state evincing its compound nature by the presence of two or more stigmata, but nevertheless unilocular, and having but one ovule. Usually called an Achene or Achenium.

Cyrenians. The philosophers of a school founded at Cyrene, a Grecian colony on the northern coast of Africa, by Aristippus, a disciple of Socrates. They held, with the Epicureans, that pleasure was the only good and pain the only evil, and were not at such pains as the latter to prove that the first could only attend on virtuous conduct; they also

differed from them in not considering absence from pain of itself to be a pleasure of the highest order. Perhaps the most favourable view of the philosophy of this sect is to be obtained from the Satires and Epistles of Horace, in which the versatility of disposition, politeness of manners, and knowledge of the world that distinguished the Cyrenians, are set forth with great clearness, and with all the ardour of an enthusiastic disciple. The grand principles of Aristippus are thus described in the couplet—

Omnis Aristippum decuit color et status et res,
Tentantem majora, fere presentibus sequimur :

and the poet's own partiality for this system of philosophy, and its accommodating character, are thus exhibited :—

Nunc in Aristippi furtim præcepta relabor,
Et nihil res non me rebus subjungere conor.

Cyrrillaceæ (Cyrrilla, one of the genera).

A small order of hypogynous Exogens, belonging to the Berberal alliance, and consisting of shrubs with regular symmetrical flowers having an imbricated corolla; the stamens alternating with the petals; axile placentæ; and pendulous ovules. They are of little interest.

Cyrtandraceæ (Gr. *κυρτός*, *crooked*, and *ἀνήρ*, *a male*; *Cyrtandra*, the name of one of the genera). A natural order of monopetalous dicarpous Exogens, inhabiting the tropics, and closely allied to *Gesneraceæ*, *Bignoniaceæ*, and *Pedaliaceæ*; differing from the former only in never producing an inferior ovary, in their deeply lobed placentæ, their siliqueous fruit, and the want of albumen; from *Bignoniaceæ*, by their habit, their minute apterous seeds, and one-celled ovary, with two double parietal placentæ; from *Pedaliaceæ*, in nothing except their minute indefinite seeds, and the membranous texture of the fruit and placentæ.

Cystibranchians, **Cystibranchia** (Gr. *κύστις*, *the bladder*, and *σπύγχια*, *gills*). A family of Isopodous *Crustaceæ*, comprehending those which have the branchiæ lodged in vesicular cavities.

Cystics, **Cystica** (Gr. *κύστις*). Rudolphi thus denominates the order of Entozoa in which the body is terminated by a cyst peculiar to one individual or common to many. The hydatid in the brain of sheep, and the

parasite which produces *measly pork*, are examples of this order.

Cystine. A term applied to the *cystic oxide*, a constituent of certain urinary calculi. Its chemical formula is $C_2 H_7 O_4 N_3$. It is sometimes voided in the form of a yellowish crystalline sand.

Cystitis (Gr. *κύστις*). Inflammation of the bladder.

Cystocèle (Gr. *κύστις*, and *κῆλη*, *a tumour*). A hernia or rupture formed by a protrusion of the bladder.

Cystotomy (Gr. *κύστις*, and *τομή*, *I cut*). The operation of cutting into the bladder for the extraction of a stone or other extraneous substance.

Cytheræa (Lat.; Gr. *Κυθήρεια*). In Mythology, a name given to Aphrodite (Venus), from the island Cythera, where she had a well-known temple.

Cytinaceæ (Cytina, one of the genera). In Botany, a natural order of Rhizanthas inhabiting the south of Europe, the Cape, and Guinea. They are very little known, and have no sensible properties of importance. Peltier says that *Cytinus* has the property of precipitating gelatin without containing tannin.

Cytisine. A purgative bitter principle, extracted from the *Cytisus alpinus*. The poisonous principle of the *Cytisus Laburnum*.

Cytisus (Lat.; Gr. *κύτις*). This plant, frequently mentioned in Greek and Latin writers, is generally supposed to be a kind of clover, the *Medicago arborea* of Linnæus.

Cytoblast (formed from Gr. *κύω*, *I hold*, and *βλαστός*, *a sprout*). In Physiology, the nucleus, cellule, or centre of assimilative force, from which the organic cell is developed.

Cytoblastema. The structureless substance in which the elementary nuclei, cellules, or cytoblasts, are embedded.

Czar, Zar or Tsar. A title given to their monarch by several Slavonic tribes. In Russia, Ivan II. adopted in 1679 the title of Czar of Moscow. The eldest son of the czar was termed Czarovitch; but after the death of Alexis, the murdered son of Peter I., this title was no more used, until revived by Paul I., in 1799, in favour of his second son, the late grand duke Constantine. The consort of the emperor of Russia is styled *Czarina*.

D

D. The fourth letter in the Hebrew alphabet and those derived from it, is the medial of the order of dentals or palato-dentals; and is susceptible of various interchanges, particularly in the German and English languages. As an abbreviation, D has several significations; thus, M.D. Doctor of Medicine; D.D. Doctor of Divinity, &c. Among Roman writers, D. is used for Divus, Decimus, Devotus, Diebus, &c. D.M.

in the Roman epitaphs signifies Diis Manibus; Deo Magno, or Diis Magnis. As a Roman numeral, D signifies five hundred: in this case, it is more correct to write *Iḡ*.

D. In Music, one of the notes of the scale, corresponding to the French *Re*.

Da Capo (Ital.). In Music, usually written short, D.C. An instruction to the performer in such airs as end with the first strain, that the

song must be begun again and ended with the first part.

Dab. [PLEURONACTES.]

Dace. [CYPRINUS LEUCISCUS.]

Dacelo. One of those generic terms which Dr. Leach framed by transposing the letters of the name of the typical or Linnæan genus from which the species so designated were dismembered; in the present case, the word is obtained from *Aleodo*, and is applied to a large Australian species of Passerine bird, nearly allied to the kingfisher.

Dacrydium. [DIAGRIDIUM.]

Dacryoma (Gr. *δακρύω*, I weep). A disease of the lachrymal duct of the eye, by which the tears are prevented passing into the nose, and therefore trickle over the face.

Dactyl (Gr. *δάκτυλος*, the finger) The name of a metrical foot in Greek and Latin poetry, consisting of a long and two short syllables; as in the word *carmīnā*. In the English and German languages, where accent determines quantity, the word *dactyl* means an accented followed by two unaccented syllables; as in *quantity*, *lieblichē*.

Dactyli (Gr. *δάκτυλοι*). A name given to the Phrygian priests who were connected with the worship of Rhea or Cybele, and are identified or confused with the Corybantes, Curetes, and Cabiri. [CABIRI.]

Dactylograph (Gr. *δάκτυλιος*, a ring, and *γράφω*, to engrave). In ancient Gem Sculpture, the inscription of the name of the artist on a gem.

Dactylography (Gr. *δάκτυλιος*, and *γράφω*, to write). In Gem Sculpture, the science of gem engraving.

Dactylology (Gr. *δάκτυλος*, a finger, and *λόγος*). The art of spelling words by placing the fingers in such positions as to signify the letters of the alphabet.

Dactylopteros (Gr. *δάκτυλος*, and *πτερόν*, a wing or fin; *finger-finned*). A fish is said to be dactylopteros when the inferior rays of its pectoral fin are partially or entirely free. The term *Dactylopteros* has been applied by Lacépède to a genus of Gurnards, remarkable for the great expansion of their pectoral fins. The most common and best known species of this genus inhabits the Mediterranean, and is the *Trigla volitans* of Linnaeus, or the flying gurnard. It is sometimes confounded with the true flying fish (*Exocoetus*).

Dado (Ital.). In Architecture, the die, or that part of a pedestal, in the middle between the base and the cornice; it takes its name from being a cube like a die. The term is also applied to the wainscoting of a room which would be supposed to represent the *dado* of the pilasters arranged round it.

Dadyl (Gr. *δαδύλον*, a torch). A hydrocarbon derived from oil of turpentine.

Dædalus (Gr. *Δαίδαλος*). In Mythology. A son or grandson of Erechtheus, king of Athens, who fled to Crete, and there built the labyrinth for the Minotaur. Being afterwards imprisoned in it himself, he with his son Icarus escaped by wings which he made. The latter

fell into the strait which bears his name, while Dædalus safely reached Sicily. The epithet *Dædalean* is applied by Homer to works wrought in wood or metal, but not of embroidery. (Grote, *History of Greece*, part i. ch. xii.)

Dæmon. [DEMON.]

Dæmonomania. The species of madness or melancholy in which the patient supposes himself to be possessed of devils.

Dagger (Fr. *dague*, Ital. *daga*). A short sword or long knife. This weapon was in use among the Franks as early as the sixth century. In the twelfth century it is mentioned as a '*cul-tellus qui dicitur dagger*,' and Walsingham in the fifteenth century calls it '*coustel or dagger*.' Towards the close of the thirteenth century it was used as part of the knightly equipment, and about this time it was called the *misericorde*, because in the last struggle the uplifted dagger caused the discomfited fighter to sue for mercy. Towards the end of the fourteenth century, knights always wore a dagger suspended by a cord or chain to the right side, and it was even sometimes used as a missile weapon. At this time it was carried by citizens, yeomen, sailors, and even ladies. It still remains in the shipman's dirk. (Hewitt's *Ancient Armour and Weapons in Europe*.)

DAGGER. In Printing, a character marked thus †, used as a reference to notes in the margin of the page. It is also called an *obelisk*.

Dagon (Heb. דָּגוֹן, dag, a fish). One of the principal divinities of the ancient Phœnicians and Syrians, and more especially of the Philistines, represented as half man and half fish. Judges xvi. and 1 Samuel v.)

Daguerreotype. The name given to a process introduced by Daguerre, by which the images from the lens of a camera obscura are transferred to metal plates. The sensitive surface of the plate is a film of iodide of silver, upon which the images are rendered apparent by exposure to the vapour of mercury. This curious and ingenious process has been almost entirely superseded by other photographic processes. [PHOTOGRAPHY.]

Dahlia (after Andrew Dahl, a Swedish botanist). The name of a Mexican genus of *Compositæ*, which has yielded one of our most popular autumnal garden flowers, although originally introduced in consequence of the estable character of the roots, which somewhat resemble a bad potato. The original dahlias bore flower-heads with a single outer row or ray of large coloured florets, and a disc or centre of smaller yellow tubular ones; but the varieties have been year by year improved under the hands of the florists, until the yellow-disc florets have been replaced by others similar to those of the ray, the whole being at the same time so modified in shape that the 'blooms' become models of symmetry.

Dahlin. [INULIN.]

Daimio. The title of the feudal lords of Japan. The Daimios are 264 in number, and exercise in their own districts the powers of

DAIRY

petty sovereigns. Eighteen of these princes are virtually independent within their own dominions; and hence arise many impediments in the way of that intercourse with Europeans which the Tycoon, or temporal sovereign of Japan, seems willing to promote.

Dairy (Old English, *dey*, a servant in husbandry who made cheese and butter; Swed. *deja*, a dairymaid). An apartment in a house, or a separate building, for the purpose of holding milk, and manufacturing it into butter, cheese, or other dairy produce. On a small scale, where butter only is made from milk, the dairy may be a room in the north side of the dwelling-house; or it may form one of the offices connected with the kitchen court. The requisites for the room to contain the milk are—an equal temperature throughout the year, viz. between 48° and 55° ; sufficient ventilation to carry off all bad smells and impurities in the air; and the exclusion of flies and other insects. An equable temperature is maintained by thick or by hollow walls, and by double windows. In winter the temperature is somewhat raised by the warm milk, and in summer it is cooled to the degree required by ventilation and the evaporation of water poured on the floor. The ventilation is effected by opening the glazed sashes of the windows, and supplying their places by wire shutters; and indeed one of the best modes of arranging the windows of a dairy is to have wooden shutters outside for closing in the most severe weather in winter; next, a fixed frame of wirework to exclude the flies; and within this, at three or four inches' distance, the glazed sash, which should be made to open. A dairy on a large scale is most conveniently arranged as a detached building; in which case, it contains a milk-room, a churning-room, and a dairy scullery, or place for scalding the utensils. If cheese is to be made, a room will be required for the cheese press, and another for drying the cheeses.

The quantity of milk raised in the vicinity of London for the supply of the inhabitants, and the revenue derived from the sale of it, show the importance of this article. In his valuable work on cattle, their breeds, &c. Mr. Youatt estimates the number of dairy-cows at present kept in London and its environs at 12,000; affording, on Mr. Middleton's hypothesis, an annual supply of 38,400,000 quarts of milk. Now, as milk is sold by the retailers at from 3d. to 4d. a quart, after the cream is separated from it, and as the cream is usually sold at from 2s. 6d. to 3s. a quart, and there is reason to suspect that a good deal of water is intermixed with the milk, we should hardly be warranted in estimating that the milk, as obtained from the cow, is sold at less than 5d. a quart, which gives 800,000*l.* as the total price of the milk consumed in the city and its immediate vicinity. (M'Culloch's *Statistics*, 2nd ed. vol. i. p. 490.)

Dais. In Architecture, the platform, or raised floor, at the upper end of a dining hall where the table intended for the principal guests stood; also the seat, with a canopy over it, for those who sat at the high table.

D'ALEMBERT'S PRINCIPLE

Dalbergia (after Nicholas Dalberg, a Swedish botanist). A genus of large tropical Eastern forest trees of the Leguminous order, yielding some most valuable timbers. The Blackwood, or East Indian Rosewood, is the timber of *D. latifolia*; and *D. Sissoo* furnishes the Sissum wood, which is much employed for purposes where hard durable wood is required. They have mostly pinnate leaves and racemose flowers, while the pods are either long, thin, and straight, or short and crescent-shaped.

D'Alembert's Principle. An important theorem first enunciated by D'Alembert in a memoir communicated to the Academy of Paris in 1742, and by means of which dynamical problems are reduced to statical ones. It may be thus explained: The particles of a rigid body being invariably connected with each other are not free to accept the motions impressed upon them by the action of externally applied forces; in other words, the effect of such forces must consist of the actual or *expressed* motions of the particles, and of certain internal strains or pressures which are overcome by the rigidity of the body. Now whatever may be the magnitude or nature of these internal strains, it is obvious that equilibrium would result if we were to oppose the given applied forces by a system of new forces, applied to the several particles of the body, and capable of imparting to each particle, considered as isolated and perfectly free, a velocity precisely equal and opposite to that which it actually receives under the action of the given forces. To express this condition mathematically, let x, y, z denote the coordinates of any particle whose mass is m , and let X, Y, Z be the components of the known force applied to it. Then t being the time,

$$\frac{dx}{dt} \frac{dy}{dt} \frac{dz}{dt}$$

will be the components of the *expressed* velocity of the particle, and

$$m \frac{d^2x}{dt^2}, m \frac{d^2y}{dt^2}, m \frac{d^2z}{dt^2}$$

the components of the force capable of giving to that particle, were it absolutely isolated from all others, precisely the same velocity. According to the principle under consideration, therefore, equilibrium must result from the simultaneous application to the body of the system of forces

$$X_1, X_2, \&c. - m_1 \frac{d^2x_1}{dt^2}, - m_2 \frac{d^2x_2}{dt^2}, \&c.$$

$$Y_1, Y_2, \&c. - m_1 \frac{d^2y_1}{dt^2}, - m_2 \frac{d^2y_2}{dt^2}, \&c.$$

$$Z_1, Z_2, \&c. - m_1 \frac{d^2z_1}{dt^2}, - m_2 \frac{d^2z_2}{dt^2}, \&c.$$

Expressing this condition in the ordinary manner [STATICS], we obtain the following six *equations of motion*, the fundamental ones in dynamics, in which the sign of summation extends to all particles of the system:

$$\sum (X - m \frac{d^2x}{dt^2}) = 0,$$

DALMATICA

$$x \left(Y - m \frac{d^2 y}{ds^2} \right) = 0,$$

$$x \left(Z - m \frac{d^2 z}{ds^2} \right) = 0,$$

$$x \left\{ y \left(Z - m \frac{d^2 z}{ds^2} \right) - z \left(Y - m \frac{d^2 y}{ds^2} \right) \right\} = 0,$$

$$x \left\{ s \left(X - m \frac{d^2 x}{ds^2} \right) - z \left(Z - m \frac{d^2 z}{ds^2} \right) \right\} = 0,$$

$$x \left\{ s \left(Y - m \frac{d^2 y}{ds^2} \right) - y \left(X - m \frac{d^2 x}{ds^2} \right) \right\} = 0.$$

A long white gown with sleeves; worn by deacons in the Roman Catholic church over the *alb* and *stole*. It was imitated from a dress originally worn in Dalmatia, and imported into Rome by the emperor Commodus, where the use of it gradually superseded the old Roman fashion of keeping the arms uncovered. A similar robe was worn by kings in the middle ages at coronations and other solemnities.

Damage-feeasant (Fr. *faisant, doing*). In Law, a beast is said to be so when found in another person's ground without his leave or license; in which case the tenant may distrain or impound it; but at his own peril, if the accident have happened through his own negligence in not repairing the fences of his close. Possession, without title, is sufficient to empower the tenant to distrain damage-feeasant. Proper notice is, however, to be given; and if the owner of the estate tender amends, it is unlawful to detain the beasts.

Damages (Lat. *damnum*, Fr. *dommage, loss*). In English Law, the recompense awarded, by a jury to a plaintiff, in certain forms of action, for the loss or *damage* he has sustained by the injury committed by the defendant. At *common law*, damages are recoverable in personal and mixed actions. In actions upon the case, trespass, &c., a certain amount of damages, sufficient to cover all the hurt really sustained by the plaintiff, is alleged or *laid* in the declaration; and it is the duty of the jury to enquire the real amount of damages, and assess it accordingly. In the action of debt, where the amount due is something certain, the damage laid is now merely nominal for the injury supposed to be done by the detention of the debt; the jury, therefore, award a nominal sum only. Damages are also allowed in actions upon a variety of statutes, and sometimes double or treble damages; in which case the plaintiff is entitled to twice or three times the amount awarded by the jury.

Damaluric Acid (Gr. *δάμαλς, a heifer*). A heavy oily liquid occurring along with *demotic acid* in cow's urine.

Damask (from *Damascus*, where it was anciently made). A woven fabric produced by a particular construction and management of the loom, in which are represented various figures of flowers, fruit, leaves, &c. The chief seat of this manufacture is Dunfermline in Fifeshire, and Lisburne and Ardyne near Belfast. The best damasks are of linen; those

DANEGELT

of cotton are cheaper, but less elegant and durable.

Damaskening (Fr. *damasquinure*). The art of inlaying metals with scrollwork and other ornamentation in gold and silver, so called from Damascus, celebrated during the middle ages for the skill of its manufacturers in this class of ornamental art. In more modern times Milan has been distinguished for its damasked armour; this decoration is very commonly applied to swords.

Damassin. A species of woven damask with gold and silver flowers.

Dame (Fr.; Ital. *dama*, probably a corruption of the Lat. *domina, a mistress*). Was formerly a title of honour, and is still used in the English law to denote the wife of a knight or baronet. *Dame* was also the designation of nuns of the Benedictine and certain other ancient orders.

(*Dammar*, its name in Amboyna). The Kaurie or Kaudi (sometimes written Cowdie) Pine of New Zealand is a species of this diocious genus of *Coniferae*, and is called *D. australis*. It yields a hard brittle resin like copal. *D. orientalis*, the Amboyna Pine, yields the fine transparent resin called *Dammar*. Several of the species furnish valuable timber. They have broad leathery leaves and great oblong cones.

Damourite. A species of Mica, found at Pontivy in Brittany. It is a silicate of alumina and potash; named after Damour, who first analysed it.

Damps (Ger. *dampf, vapour*). The noxious exhalations of mines and excavations. The carburetted hydrogen of coal mines is called *fire damp*; carbonic acid is termed *choke damp*.

Danaë. [PERSEUS.]

Danaïde. [HYDRAULIC DANAÏDE.]

Danaite. A variety of arsenical pyrites, found at New Hampshire, United States.

Danburite. A hydrated silicate of lime from Danbury in Connecticut.

Dancing (Ger. *tanzen, to dance*). May be defined as a graceful movement of the figure, accompanied by gestures and attitudes indicative of certain mental emotions, and by measured steps in harmony with a piece of music arranged for the purpose. The origin of all dancing is connected with religion; and the practice of it involved great labour and skill, the war dances serving as an actual preparation for war. In the ancient dancing the sexes were never mingled. When dances ceased to be religious, then it became disgraceful for Roman citizens to take part in them. Almost every country can boast of national dances peculiar to the inhabitants; which are rarely so well performed when adopted by others. Of these the best known to us are the *tarantella* of the Neapolitans, the *bolero* and *fandango* of the Spaniards, the *masourek* and *krakovieck* of Poland, the *cosack* of Russia, the *redowac* of Bohemia, the *quadrille* and *cotillon* of France, the *waltz* and *gallopade* of Germany, and the *reel* of Scotland.

Danegelt. A tribute of twelve pence laid

by the Danes upon the Anglo-Saxons for every hide of land throughout the realm.

Dannebrog. The red cross of Denmark. The tradition is that (like Constantine) Waldemar II. of Denmark saw in 1219 in the heavens a fiery cross which betokened his victory over the Esthonians. The order of knighthood, which is supposed to have been founded in commemoration of that event, was revived in 1693, and reconstituted in 1808.

Dannemorite. A species of Hornblende from the iron mines of Dannemora in Sweden.

Dans. Small trucks or sledges used in coal mines.

Dantzic Fir. The fir timber imported from the Prussian port of Dantzic; it is generally speaking considered the best description of fir, and is usually prescribed in specifications for this reason. It can be obtained as much as 70 feet in length by about 16 inches square. The Dantzic oak is also highly esteemed.

Daphne (Gr.). A genus of *Thymelacæ*, consisting of shrubs widely dispersed in various parts of the world. *D. Mezereum*, the Mezereum, a deciduous species found wild in woods, possesses medicinal properties, as also does the Spurge Laurel, *D. Laureola*. The fibrous bark of some of the Indian species is made into paper.

DAPHNE (Gr.). In Greek Mythology, a nymph beloved by Apollo. To escape his pursuit, she besought the aid of the Earth, which opened to receive her; and a laurel, called after her name, grew up on the spot. The name is identified with the Sanscrit Dahanâ, the Dawn. [MINERVA.]

Daphnia. A genus of the Entomostracous or lower-organised Crustaceans, belonging to the order *Branchiopoda*, and the section *Lophypodopa*. The most common species and type of this genus, *Monoculus pulex* of Linnaeus, is a favourite and interesting microscopic object.

Daphnine. A crystalline non-azotised substance found in the bark of certain species of *Daphne*. It is bitter, astringent, and slightly acid. When heated, it yields a crystalline product, *Daphnetine*.

Dapico. The South American name of a species of *Caoutchouc*, obtained from the roots of *Siphonia elastica*.

Darby. A tool used by plasterers to float a ceiling; it is about 3 feet or 3 feet 6 inches long, by 7 inches in width, and has two stout handles fastened on the back, to enable the workmen to hold it.

Daric (Gr. *dapeîds*). A Persian gold coin (so called by the Greeks, from Darius, the name of several Persian sovereigns), having upon the obverse an archer crowned and kneeling upon one knee, and on the reverse a quadrata incusa, or deep cleft. The weight of the daric is about 130 grains.

Darce-tree. The *Sycomorus antiquorum*, or Egyptian sycamore or fig.

Darter. Certain web-footed birds of the Pelican family are so called. [FLORUS.]

Dash. In Music, a small mark, thus †, denoting that the note over which it is placed is to be performed *staccato*, i. e. in a short, detached, distinct manner.

Dasyprocta (Gr. *δασύπρωκτος*). The sub-generic name applied by Illiger to the *Aguti* and *Acuchi*, which before were included in the great genus *Cavia* of Linnaeus.

Dasypros (Gr. *δασύπρος, rough-footed*). A name originally and very appropriately applied by the Greeks to the hare, but transferred by Linnaeus to the genus including the Armadillos. This genus is subdivided in modern systems into *Dasypros* proper, *Tatusia*, and *Prionodon*. The remains of a gigantic extinct animal of the armadillo kind have recently been discovered in South America, and called *GLYPTODON* [see that word].

Dasyurus (Gr. *δασύς*, and *οὐρα, a tail; hairy-tailed*). The name of a genus of Carnivorous Marsupials, comprehending those which have hairy tails combined with digitigrade feet, and a dental formula of: incisors $\frac{8}{6}$, canines $\frac{2}{2}$, prem.

$\frac{2}{4}$, mol. $\frac{8}{8}$, = 42.

Data (Lat. *things given*). The quantities or conditions which are assumed to be known in any geometrical problem. Thus in the problem, *Given the base, altitude, and area, to construct the triangle*, the data are: 1. That the figure is a triangle; 2. That it has a certain straight line for its base; 3. That its vertex is at a known distance from this base; and 4. That its area has a known magnitude. Here the data are distinguished from the *quæsitum*, which is the triangle itself; frequently, however, the term *datum* is extended to everything that is *determined* by the given conditions, magnitudes, &c. It is in this sense that Euclid understood the term in his *Book of Data*, translated by Simpson and Horsley. Marinus, one of the disciples of Proclus, wrote a preface to Euclid's *Data*, which contains a dissertation on the meaning of the term.

Date. In Diplomats, the notation of the time and place of the delivery or subscription of an instrument. The word is derived from the common formula at the foot of instruments, 'datum,' or 'data,' *given* at such a place and time. Dates of time are distinguished into definite and indefinite. The former mark specially the year, and sometimes the month, day, &c.; the latter only contain a general reference to some period of time. Thus many instruments of the earlier part of the middle ages contained only mention of the reigning prince, without reference to the years of his reign. Definite dates are various in ancient charters and deeds. The Christian Greeks dated generally, down to the fall of Constantinople, by the year of the world; beginning their year at September 1. The date used in the oldest Latin charters is commonly that of the Indiction [INDICTION], which is also frequently added in the Greek. The Christian era (under the several names of *year of grace*, of the *incar-*

DATES

nation, of the reign of Christ, of the nativity, &c. &c.) began to be in common usage in royal charters in France about the reign of Hugh Capet; in Spain and Portugal not until the thirteenth and fourteenth centuries. In England, the kings before the Norman Conquest frequently dated by the Incarnation; but deeds and charters under the Plantagenet kings generally bear the year of the reigning prince.

Dates. The fruit of the Date Palm (*Phoenix dactylifera*). They contain from thirty to forty per cent. of sugar.

Batholite or Datolite. A mineral composed of silica, lime, and boric acid; a borosilicate of lime. It occurs in Norway, in the Tyrol, and in the Harz. It becomes opaque when heated; hence the name, from Gr. *δάτος*, *turbid*.

Datisaccese (*Datisca*, one of the genera). A natural order of Exogens belonging to the Cucurbitall alliance, and known by their apetalous flowers, parietal placentæ, and dry fruit. They occur in North America, Northern Asia, and the Eastern Archipelago.

Datiscin. A name given by Braconnot to a substance having the appearance of grape sugar, which he extracted from the *Datisca cannabina*.

Dative Case (Lat. *dativus*, from *do*, *I give*). That inflexion of a noun which denotes participation in the action of the verb which accompanies it. [GRAMMAR.]

Datura (Arab *tâtôrâh*). The Thorn-apple, a poisonous medicinal annual herb, is the most familiar example of this genus of *Solanaceæ*. It is called *D. Stramonium*, and is known by its forking stem, ovate sinuately-toothed leaves, and white funnel-shaped flowers succeeded by prickly four-valved fruit containing many black seeds.

Daturia. The poisonous principle of the *Datura Stramonium*. It belongs to the class of crystallisable alkaloids.

Daub. A rough kind of plastering, thrown, or cast, upon a wall, and also applied to the clay which is thrown upon the surface of the wattles, or sticks, in rough farm buildings.

Daucus (Gr. *δαῦκος*, Lat. *daucum*, a *carrot*). The genus of Umbellifers which contains the carrot, *D. Carota*, the succulent cultivated form of which has no doubt been produced by successive improvements, under the hands of cultivators, from the wild original, which is abundant on our coasts. Carrots are wholesome and nutritious, both as esculent vegetables, and as food for cattle.

Dauphin. The well-known title of the heir-apparent to the crown of France, before the Revolution. was that of the counts or lords of Vienne in Dauphiné, from the twelfth century, or an earlier period. In 1349, Humbert, lord of Vienne, made John, son of Philip of Valois, his heir. For some time the principality was governed by the Dauphin as a separate state, but was reunited to the crown in 1467. (Hallam's *Middle Ages*, chap. i. part ii. note k.)

DAY

Daurite. A variety of Tourmaline.

Davidsonite. A mineral discovered by Dr. Davidson in the granite quarry of Rubialaw, near Aberdeen: it is a *silicate of alumina*.

Davit. On Shipboard, a stout beam of timber, employed in hoisting the anchor. Its use is to enable the anchor to be so hauled up that the flukes shall not injure the vessel's sides. It is not fixed, but is removed from side to side as required. Davits are also projecting cranes for raising from and lowering into the water the ship's boats. They are arranged in pairs (two for each boat) along the sides and at the stern.

Davite. A name given to a fibrous sulphate of alumina found in a warm spring near Bogota, in Columbia.

Davyne. A white or brown crystallised mineral found in cavities of some of the lapideous masses ejected by Vesuvius.

Dawn. [TWILIGHT.]

Day (Ger. *tag*). In its most common acceptation, this word denotes the interval of time during which the sun remains above the horizon; and is opposed to *night*, which denotes the time the sun is below the horizon. In this sense it is sometimes called the *artificial day*. But the term *day* is also generally used to denote the time in which the earth makes a complete revolution with respect to the celestial bodies, and consequently expresses different intervals, according as the body with which the earth's rotation is compared is fixed or movable.

The *Astronomical* or *Solar Day*, called also the *Apparent Day*, is the time that elapses between two consecutive returns of the same terrestrial meridian to the centre of the sun. Astronomical days are not of equal length, for two reasons: 1st, the unequal velocity of the earth in its orbit, in consequence of which the apparent daily motion of the sun is greater in winter than in summer; and 2nd, the obliquity of the ecliptic, in consequence of which the sun's apparent daily motion in right ascension (that is, in the plane of the earth's equator) is less at the equinoxes than at the tropics. The astronomical day commences at noon, and is counted on through the twenty-four hours.

The *Civil Day*, or *Mean Solar Day*, is the time employed by the earth in revolving on its axis, as compared with the sun, supposed to move at a *mean* rate in its orbit, and to make 365.2425 revolutions in a mean Gregorian year. In this mode of reckoning time, the days are all of the same length; and noon, or any given hour of the civil day, sometimes precedes and sometimes comes after apparent noon, or the corresponding hour of the astronomical day. Most nations, at least in modern times, have agreed in placing the commencement and termination of the civil day at mean midnight.

The *Sidereal Day* is the time that elapses between two successive culminations of the same star. This interval of time has always within historical memory remained of the same invariable length, as is proved by the most

DAY-SIGHT

ancient astronomical observations. It is divided into 24 sidereal hours; and these are again subdivided into sidereal minutes and seconds. This mode of reckoning time, during the day, is now universally adopted by astronomers in their observatories. [TIME.]

Day-sight. A condition of the eye in which vision is clear in the day, but dull and confused at night. It is said to be common in some parts of Russia. In Canada it is termed *night-blindness*, and is attributed to the effect of snow on the eyes.

De Facto (Lat.). A legal phrase, denoting actual possession, however acquired; while the term *de jure* indicates a right of title which may or may not be accompanied by possession.

De Jure. [DE FACTO.]

De Luc's Column. An alternation of different substances, such as silver, zinc, and thin paper; which produce an electric arrangement. It is sometimes called the *dry pile*.

Deacon (Gr. *diakonos*, a minister or servant). A minister of religion, holding, in Protestant churches, the lowest degree in holy orders. The first appointment of deacons is mentioned in Acts vi., where the Apostles direct the congregation to look out seven men of honest report, upon whom they may lay their hands. Their office at this time was chiefly the care of the poor and the distribution of the bread and wine in the love feasts; but they also had authority to preach. In the English church it is customary to require a candidate for deacon's orders to have completed his twenty-third year. He is not capable of holding any benefice, and may only officiate as a curate, chaplain, or lecturer; he may not read the Absolution, nor administer the sacrament alone, but in assisting the priest may offer the cup to the communicants. In Scotland, the term *deacon* is applied to a corporate officer.

Dead Beat. In Clockwork (called also *dead escapement*, or *escapement of repose*), a peculiar kind of escapement invented by Mr. George Graham about the year 1700, with a view to lessen the effect of the wheelwork on the motion of the pendulum; it acquired its name from the circumstance that the seconds' index stands still after each drop, whereas the index of a clock with a *recoiling escapement* is always in motion, hobbling backward and forward. [HOROLOGY.]

Dead Colour. In Painting, a colour is said to be dead when it has no gloss upon it; this is generally effected by the use of less oil and more turpentine than in ordinary paints.

Dead Ground. In Fortification, ground which cannot be seen or defended from behind the parapet of the work.

Dead Lights. Strong wooden posts or shutters put over the glass windows of the cabin in bad weather, as a defence against the sea.

Dead Nettle. [LANTUM.]

Dead Oil. [COAL TAR.]

Dead Plate. A flat iron plate sometimes fitted before the bars of a furnace for the pur-

DEAD SEA

pose of allowing the bituminous coal to assume the character of coke before it is thrust back upon the fire.

Dead Reckoning. A term used in Navigation to express the estimation that is made of a ship's place without having recourse to observation of the heavenly bodies. It is made by observing the way she makes by the log, and the course on which she has been steered, making allowance for drift, leeway, &c.

Dead Sea. The name given to a remarkable tract of country in Palestine, depressed very considerably below the sea level, but only covered with water in the deepest parts. The depression—meaning by that expression the area below the level of the sea—is a long narrow basin, the length being 200 miles, and the breadth less than 20 miles. About one-fourth is now covered by water. It includes the two lakes called the Dead Sea and the lake of Tiberias, which are 60 miles apart, and the river Jordan, by which they are connected. The depth of the ordinary surface of the water of the Dead Sea below the Mediterranean is 1,388 feet, and the depth of water in its deepest part is 1,350 feet, showing a total depression of 2,738 feet. The adjacent land, however, is a table-land 3,000 feet above the Mediterranean, so that the whole gorge is nearly 6,000 feet deep; this gorge is continued, though less abruptly, through the Red Sea into the Indian Ocean. A low watershed, 113 feet above the Red Sea, separates the waters of the Dead Sea from those that communicate southwards with the Indian Ocean.

The properties of the waters of the Dead Sea are remarkable and well known. They are: 1. Great specific gravity—amounting to 1.25, or one-fourth greater than pure water, so that many substances float in it which sink at once in a pond or the sea; and, 2. Intense saltiness, nearly seven times that of the sea, but varying extremely at different seasons, being sometimes only about 22 per cent. and at other times more than 44 per cent. of the whole. About 24½ per cent. may be considered the average proportion by weight. The chlorides of sodium, magnesium, and calcium are the most abundant salts, and there is also some chloride of potassium. Assuming that the whole depression was originally covered with sea-water, and evaporated down to its present state after communication with the sea had been cut off, the supply of fresh water being insufficient to meet the evaporation, there would be a deposit of common salt and carbonate of lime formed at the bottom during a large part of the year, and after rain other deposits with less salt would alternate. 'In this way,' says Bischof (*Elements of Chemistry and Physical Geology*), 'there must arise a constant alternation of different irregular layers of greater or less thickness. All these layers must contain gypsum, since in a water which holds so much chloride of magnesium as is present in the Dead Sea, gypsum is dissolved with difficulty, so that all the sulphate of lime originally in the sea-

DEAD SEA

water, as well as that carried in by the rivers, will be carried to the bottom.' There can be little doubt that this as well as many other known deposits of salt may have been formed in the way here indicated.

There is reason to suppose, from ancient sculptures in Egypt, that the level of the waters of the Dead Sea is not lower now than it was three thousand years ago. The balance has probably long been struck between evaporation and water-supply. On the whole, the evidence with regard to the Dead Sea and the country near it shows the existence of a remarkable fissure, not greatly unlike some of the floods of Norway. This fissure extends first from the base of Mount Hermon to the Red Sea, a distance of 350 miles, where it meets the gulf of Suez, and thence nearly in a straight line for a further distance of about 1,200 miles to the straits of Bab-el-Mandeb.

This great fissure separates Asia from Africa, and its breadth increases gradually, with the intervention of some necks, from a few yards in the north to as much as 200 miles at the opening of the Indian Ocean; while the depth, though not fully known, is in the Dead Sea, and probably throughout, but also with intervals of shallowing, more than 400 fathoms below the level of the Mediterranean.

By this contraction and shallowing, the fissure is divided into three basins, the main body of the Red Sea, the gulf of Akabah, and the depression of the Wady-Arabah, the latter including the Dead Sea and the valley of the Jordan.

The gulf of Akabah and the Red Sea are still connected by a narrow strait, which has an island in the middle and two banks or shoals projecting from it in opposite directions, leaving intermediate channels, the best of which is little more than half a mile wide, though of great depth.

It is only necessary to suppose that the depression to the north, now left dry, was formerly also covered with water, and separated from the gulf of Akabah by the gradual elevation of the land now forming the watershed on an axis transverse to that of the original fissure, to account for the separation of the former gulf from its southern continuation; and then the natural process of evaporation, continued for a sufficient period, could only result in the phenomena now presented. Should the channel between the gulf of Akabah and the Red Sea be closed, a similar result must happen.

It is interesting to observe that the gulf of Suez, the north-western fork of the Red Sea, was formerly continued in all probability to the Mediterranean, but is now cut off by the isthmus of Suez, in which there remains a small basin depressed below the Mediterranean, and also occupied by a salt lake like the Dead Sea. The lofty elevations of Dzebel Tor (Mount Sinai) and the volcanic nature of the rocks in parts of the wilderness between Egypt and Palestine are fully sufficient to justify the assumption of a comparatively recent elevation in this part of the great land of the old continent.

SECTION OF THE FISSURE FROM MOUNT HERMON TO THE RED SEA.

Dead Water. The water that closes in with a ship's stern.

Dead Well. A well through which the refuse waters of certain industries, or even cess-pools, are allowed to infiltrate into the subjacent strata, which are usually of a permeable nature. In France no dead well can be established without an authorisation from the prefect of the department; but in England there is no legislation upon the subject, and all the wells in a neighbourhood may thus be poisoned by the establishment of one of these dead wells.

Dead-eyes. On Shipboard, a species of blocks without sheaves. Each has usually three holes through it. They are employed in tightening the standing rigging; one dead-eye, for instance, being fastened to the chain and another to the foot of the shroud; these are then

connected by a lanyard passed through the holes in the dead-eyes. By tightening the lanyard, the tension of the shroud can be increased until the dead-eyes touch.

Deadening Way. In Navigation, the process of gradually checking the ship's way through the water.

Deadhead. The extra length of metal given to a cast gun. It serves to contain the dross, which rises to the top of the liquid metal, and which, were it not for the *deadhead*, would be at the muzzle of the gun. When cooled and solid, the deadhead is cut off.

Deafness (Ger. taub, *deaf*). An imperfection of the sense of hearing, arising from a variety of causes, some of which are inextinguishable and incurable, and others ascertainable and susceptible of relief or entire removal. When the organ of hearing is imperfect in its

DEAFNESS

functions, either at birth or in childhood, dumbness or imperfect articulation attends it; for speech is an imitative faculty, and an infant born deaf cannot attempt those motions of the organs of voice which gradually attain perfection by practice; he consequently becomes incapable of communicating his ideas through that medium.

The external ear, though tending by its form and situation to improve and perfect the sense of hearing, is in no way necessary; for it may be cut off without producing deafness. A common cause of deafness arises from imperfections or obstructions in the passage leading from the external ear down to the membrane of the tympanum. This passage is partly cartilaginous and partly bony; and from its oblique direction it is difficult so to see into it as to ascertain the seat or cause of the obstruction. In some persons, however, when placed in a proper position, so that the sunshine or other strong light may be properly directed into it, a little management enables us to examine nearly its whole extent. In some cases of congenital deafness this passage is closed by a membrane, which, if near the external orifice, is easily detected, and may be divided or removed; but, if deeply seated, it may escape observation till the child attains a certain age, or should begin to talk; for till that time the deafness of infants often passes unobserved. Under these circumstances, and where the malformation exists in both ears, and the child is dumb as well as deaf, a timely operation may effect the double benefit of giving both hearing and speech. Where the passage to the tympanum is more extensively obliterated or malformed, the cases become of course more complicated, but yet often admit of cure by a skillful and timely operation.

The presence of foreign bodies in the aural passage is a common cause of imperfect hearing, and sometimes it is obstructed by accumulations of hardened wax. These causes of deafness may in most cases be relieved or removed by syringing the ear with warm water, which should be forcibly injected, and so directed as to reach the membrana tympani. Insects or worms in the ear may be washed out in the same way, or killed by the introduction of a few drops of olive oil, or of camphorated oil.

Another cause of deafness is deficient secretion of wax, occasioning a dryness of the tube of the ear. It is relieved by greasy applications, and by the cautious use of stimulants, such as olive oil, to which a few drops of oil of turpentine, or of compound camphor liniment, or spirit of ammonia, have been added.

In cases of inflammation of the tympanum followed by suppuration, more or less deafness ensues, dependent upon the extent of the mischief going on, and requiring prompt, and generally antiphlogistic treatment: the pain, especially at the outset of the disorder, is often intense, and the discharge purulent and offensive. The deafness that attends a violent cold

DEATH

is frequently dependent upon obstructions in the Eustachian tube, and goes off when the secretions of the part return to their natural state.

Lastly, hardness of hearing often appears to depend upon imperfection in the functions of the auditory nerves, in which case constitutional rather than local treatment must be resorted to.

Deal. In Architecture, the small thickness of timber into which a piece of wood of any sort is cut up; but the term is at present improperly confined in its signification to the wood of the fir-tree cut up into thicknesses in the countries whence deals are imported, viz. Christiania, Dantzic, St. Petersburg, &c. Their usual thickness is three inches, and their width nine inches; they are purchased by the hundred, which contains 120 deals of twelve feet length, be their thickness what it may. The best deals are those obtained from Guffe, St. Petersburg, Christiania or Dramm in Norway.

Dean (Lat. decanus). An ecclesiastical dignitary in cathedral and collegiate churches, being the head of the chapter of canons or prebendaries, and forming together with them a council to advise the bishop in the affairs of his see. [CHAPTER.] In England there are, properly speaking, three classes of ecclesiastical presidencies to which the title *dean* belongs: deans rural, deans of cathedrals, and deans in peculiars. Rural deans were originally beneficed clergymen appointed by the bishop to exercise a certain jurisdiction in districts of his diocese remote from his personal superintendence. They seem to have been equivalent in many respects to the chorepiscopi of the early church, and many parts of their office are now discharged by the archdeacons. Rural deans are still occasionally employed in visitations, to examine into the state of repair of churches, and performance of divine service; their functions had for many years become almost obsolete, but in recent times have been generally revived in the English dioceses. Deans of cathedrals have already been noticed. The third species of deans, or deans in peculiar, are those of 'particular parishes and churches, or rural districts that have jurisdiction within themselves, and are not under the ordinary of the diocese.' These are very few in number, as the deans of Bocking, Battle, &c. In Scotland, the head of the faculty of advocates is called the *dean*, and in the Scottish municipal system, the *Dean* of Guild is the second magistrate, having the care of all buildings, public and private, and discharging functions somewhat equivalent to those of the Roman *ædile*.

Death (Ger. tod). Has been defined by Dr. J. Hughes Bennett as the permanent cessation of those properties and functions which constitute LIFE [which see]. It is either local or systemic. Local death is exemplified in mortification, ulceration, necrosis, or caries. Systemic death may be reducible to three several modes: 1st. Death by syncope, i.e. beginning at the

DEATH WATCH

heart; 2nd. Death by asphyxia, at the lungs and 3rd. Death by coma, at the brain. It may be also produced by a combination of two or three of these modes: e.g. chloroform may kill, from the conjoined stupefying action of the brain, as well as the difficulty of respiration coma, through pressure on the brain affecting the *medulla oblongata*, may influence the pneumo-gastric nerve, which send branches to the heart and lungs.

Death Watch. [ANOSMUS.]

Débacle (Fr.). A rush of waters, breaking down all opposing barriers, and carrying away and dispersing the broken fragments of rocks.

Debenture. In a general sense, any writing which acknowledges a debt; but it is more particularly applied to custom-house certificates entitling the exporter of goods to a drawback or bounty; and to the acknowledgments given by railway companies for special loans, as distinguished from ordinary shares. The term also signifies an instrument in use in some government departments, by which government is charged to pay to a creditor or his assignee the sum found due on auditing his accounts.

Déblai (Fr.). In Fortification, the quantity of earth excavated from the ditch to form the parapet. [REMBLAI.]

Débris (Fr.). In Geology, the fragments of rocks, &c.

Debt (Lat. debitum, from *debeo*, *I owe*). In Law, is a species of contract, whereby a *chose in action*, or right to a certain sum of money, is mutually acquired and lost: usually divided into debts of record, debts by special contract, and debts by simple contract. A debt of record is a sum which appears to be due by the evidence of a court of record; such as debt on judgment or recognisance. Debt by specialty is where a sum is acknowledged to be due, or becomes due, by instrument under seal; such as a covenant, bond, &c. Both these species of debts, being contracted by a man for himself and his heirs, attach on his lands and tenements, and bind them in the hands of his heir or devisee. Debt by simple contract is either by parole or by written obligation unsealed; within which class fall bills of exchange and promissory notes.

DEBT is also a personal action of contract, in which the plaintiff seeks the recovery of a debt; i.e. a *liquidated* or certain sum of money alleged to be due to him. [ACTION.]

Debt, National. [NATIONAL DEBT.]

Début (Fr.). In its most general acceptation, is applied to the commencement of any undertaking, or to the first step made in a public career; but it is confined more particularly to the language of the theatre, in which it signifies the first appearance of an actor, or his first appearance on any particular stage.

Decade (Gr. *deka*). A word used by some old writers in a general sense for the number ten, or an enumeration by tens; but more peculiarly appropriated to the number of books into which the history of the Roman empire by Livy is divided, each division consisting of ten

DECAPOD

books or *decades*. It was also the name given to the space of ten days, which in the French republican calendar was substituted for the ordinary week. Thus, except in bissextile years, the whole number of decades was thirty-six and a half: the days of the half-decades, falling at the close of the year, were at one time called *sextulotides*, and afterwards *complementary*; and dedicated respectively to Virtue, Genius, Labour, Opinion, and Reconscience.

Decagon (Gr. *deka*, *ten*, and *gonia*, *an angle*). A geometrical figure, having ten sides and ten angles. If the sides and angles are all equal, the figure is a regular decagon, and inscribable in a circle. Euclid, in the fourth book of his *Elements*, shows that the side of a regular decagon is equal to the greater segment of the radius of the circumscribing circle divided by a medial section, or so that the rectangle contained by the whole radius and one of the parts is equal to the square of the other part; consequently, if we denote the radius by r , and the side of the decagon by s , we shall have the proportion $r : s :: s : r - s$; whence $s^2 + rs = r^2$, and by solving the quadratic $s = \frac{1}{2}r(\sqrt{5} - 1)$. If the radius is unit, $s = \frac{1}{2}(\sqrt{5} - 1) = .618034$; and the area = $7.694209 \times s^2$, or 7.694209 of the square on the side.

Decalitre (Fr.). A measure equivalent to ten litres. [LITRE.]

Decalogue (Gr. *deka* *logos*). The name given to the ten commandments contained in Exod. xx. That their number was understood by the Jews to be ten appears from Exod. xxxiv. 28; but they differed from us in the manner of dividing them, considering our first and second as one, and separating the last into two. The same method is adopted by the Romish church, which professes to follow the authority of St. Augustine. (*Catechismus ad Parochos*.)

Decameron (Gr. *deka*, *ten*, and *hēmera*, *day*). The name given by Boccaccio to his celebrated collection of tales: they are supposed to be narrated in turn, during ten days, by a party of guests assembled at a villa in the country to escape from the plague which raged at Florence in 1348.

Decandrous (Gr. *deka*, and *andros*, *a male*). In Botany, a plant having ten stamens.

Decantation. The pouring off a clear liquid from its subsidence or residue; it is often resorted to in the chemical laboratory instead of filtration, the clear supernatant liquor being poured or siphoned off from precipitates, which may thus be repeatedly washed or edulcorated, so as to free them from all soluble matters.

Decapitation. A mode of punishment of great antiquity. Among the Continental nations of modern times it is the ordinary punishment inflicted on all capitally convicted criminals. In England it long ago became a punishment appropriated only to criminals of the highest rank. The last instance of the infliction of this punishment in England occurred in 1746, soon after the rebellion in Scotland had been quelled.

Decapod, Decapoda (Gr. *deka*, and *pous*, *foot*; *ten-footed*). A name applied by Dr.

DECAPTERYGIANS

Leach to a tribe of Cephalopoda, including those which have ten locomotive and prehensile appendages proceeding from the head; two of which are always longer than the rest, and are called *tentacles*. Also applied by Cuvier to designate an order of Crustaceans, comprehending those which have ten thoracic feet.

Decapterygians, **Decapterygia** (Gr. *deka*, ten, and *pteron*, pinion). A name given by Schneider to an artificial division of fishes, including those which have ten fins.

Decarbonisation of Cast Iron. This process is resorted to in order to convert cast iron into steel, or by a further decarbonisation to reduce it to the state of malleable iron. Hence, many articles which were formerly exclusively manufactured of wrought iron are now cast, and afterwards decarbonised, such as horse-shoes, &c.; and in other cases various cutting instruments are cast, and afterwards brought to a proper condition by a similar process. The articles to be decarbonised are packed in finely powdered hematite, or native oxide of iron, and exposed for a

to a high red heat. It is often necessary to mix iron filings or turnings with the hematite: these substances, thus applied, gradually abstract the excess of carbon in cast iron, and reduce it to a state analogous to that of steel; or, by a longer continuance of heat, to that of soft iron. Decarbonisation may also be effected by blowing a current of air through cast iron in a state of fusion, by which, if carefully performed, a part, or the whole, of the carbon may be burnt and driven out in the form of carbonic acid.

Decastyle (Gr. *deka*, ten, and *styla*, columns). In Architecture, a building having ten columns on the front or on the flank.

Decasyllabic. Having ten syllables. In the German and English languages the ordinary heroic verse is decasyllabic; but a short syllable is sometimes added at the end by way of variety, and this, in consequence of the structure of those languages, takes place more frequently in the former than the latter. In the Italian heroic verse the eleventh syllable is almost uniformly added, and hence it is more properly to be termed an *hendecasyllabic*. In French versification the decasyllabic line is appropriated to light compositions, especially tales.

Decay. The gradual destruction of building materials is known in works upon Architecture by this name. It differs from decomposition, inasmuch as decay may take place without any change in the nature of the constituent elements of the stone; whereas decomposition always implies that a change of some kind has taken place. (*Dictionary of Technical Terms by the Architectural Publication Society*, art. 'Decay'.)

DECAY. [*ENHYPNAGMUS*.]

IN (Lat. *decem*, ten). The tenth month in the calendar of the ancient Romans, who began the year with March.

Decemviri (Lat.). Properly anybody of ten

DECIMAL FRACTION

men appointed for particular purposes. But that which is especially known by this name was the commission elected from the Roman patricians in what is called the 302nd year after the foundation of the city, and invested with all the supreme powers of the state, for the purpose of drawing up a body of laws founded, according to Roman tradition, on the more approved institutions of Greece. They presented to the people a number of laws engraved on ten tables, containing a summary of the privileges to be enjoyed by the people, and the crimes to be punished, &c. At the same time they informed the people that their plan was incomplete; and accordingly a new commission, to which the plebeians were admitted, was appointed for the next year, with the same powers; the result of which was the addition of two more tables to the former ten, thus making up the famous twelve tables, which were the foundation of all Roman law in subsequent times. The second decemvirate, we are told, did not demean itself with the same moderation as the first, but sought to prolong its power, and at the same time proceeded to some violent acts of despotism, which so exasperated the people as to make its dissolution necessary. But the whole history of the decemvirate is full of inconsistencies and difficulties, which have been forcibly exhibited by Sir G. Cornewall Lewis, in his work on the *Credibility of Early Roman History*. [TWELVE TABLES.]

Besides these extraordinary commissions, there was a body of decemviri chosen for judicial purposes, to preside over and summon the centumviri, and to judge certain causes by themselves. There were likewise decemviri appointed from time to time to divide lands among the military.

Deceptive Cadence. In Music, a cadence in which the final close is avoided by varying the final chord.

Decidua (Lat.). In Anatomy, a product or an alteration of the mucous membrane of the uterus, preparatory to the reception of the impregnated ovum, which is discharged at parturition. When the ovum enters the uterus, it becomes embedded in the decidua, which yields and is protruded inwards, and becoming more and more inverted as the ovum grows, it is called the *decidua reflexa*, while the other part of the membrane is called the *decidua vera*.

Deciduous (Lat. *deciduus*). In Botany, is applied to plants whose leaves fall off in the autumn, in contradistinction to evergreens.

Decrepous. In Zoology, a term applied to parts which have but a temporary existence, and are shed during the lifetime of the animal, as certain kinds of hair, horns, and teeth.

Decimal Arithmetic. The common system of arithmetic, in which the scale of numbers proceeds by tens. [ARITHMETIC.]

Decimal, Circulating or Recurring. [CIRCULATING OR RECURRING DECIMAL.]

Decimal Fraction. A fraction whose denominator is a decimal number or power of

DECIMAL OR METRICAL SYSTEM

Thus $\frac{1234}{100}$ is a decimal fraction. It may be decomposed into the sum

$$\frac{1000}{100} + \frac{200}{100} + \frac{30}{100} + \frac{4}{100}$$

$$= 10 + 2 + \frac{3}{10} + \frac{4}{100}$$

By an obvious extension of the method of local values, where each digit has ten times the value of the like digit which immediately succeeds it, the above decimal fraction may clearly be written more concisely in the form 12·34, where the *decimal point* after the 2 merely serves to indicate which digit represents *units*. In this abbreviated form a decimal fraction is termed a *decimal*. For the purpose of indicating the unit's place, other and less objectionable methods have been proposed. Sir Isaac Newton's method, however, of using a point, placed for distinction near the top of the figures, is the one most commonly employed. The operations of addition, subtraction, multiplication, and division may be applied to decimals in exactly the same manner as to integers; hence their great utility. The only additional rules in decimals refer to the position of the decimal point, and these are easily retained.

Decimal fractions appear to have been introduced by Regiomontanus, about the year 1464; but Stevinus was the first who wrote an express treatise on the subject, in his *Practique d'Arithmétique*, published in 1582. In their abbreviated form, as decimals, they are now universally employed in all arithmetical calculations; and it is much to be regretted that a decimal division of weights, measures, money, &c., has not been adopted in all civilised countries, by which the reduction of fractional parts from one scale to another would be obviated, and all the applications of arithmetic to the ordinary purposes of life greatly simplified. A subdivision of weights and measures on this principle was adopted in France at the time of the Revolution, but has only been partially imitated by other countries.

Decimal or Metrical System. The plurality of weights and measures in the various parts of France, due to the fact that the kingdom had been at different periods divided into several independent, or nearly independent, governments, was found to be a serious hindrance to internal trade. This evil had long occupied the attention of the French savans, and a remedy was at length proposed by the Constituent Assembly. It was conceived that the universal adoption of a system of weights and measures which should be based on some natural and invariable element would be a great international benefit, and the National Assembly petitioned the king by a decree of May 8, 1790, to the effect that communications should be made to the king of Great Britain, in order to procure the concurrence of the English parliament, for the establishment of a joint commission of the Academy of Science

and the London Royal Society, whose business should be the carrying out an international system of weights and measures. The decree contains a suggestion that the basis of the system should be taken from the length of a pendulum at the latitude of 45° north. The scheme did not, it seems, attract much attention in this country; and Macpherson, whose collection of facts bearing upon trade and commerce at this period is very minute, makes no mention of the proposal.

A commission, however, was formed in France, of which Laplace was a member. It continued its workings during the time of the revolutionary government, and some persons served on it even from other countries. After the break-up of the Republic, the scheme, like every act of the revolutionary era, became unpopular, though during the consulate Napoleon gave in his adhesion to the plan, and furthered it. After a time, however, he became one of its strongest opponents. The metrical system was equally unpopular under the régime of the Restoration, the elder Bourbons identifying it with the dogmas of the Revolution. Still it had been for some time used by many scientific and professional bodies, and by some official departments, as, for instance, the French Board of Works and the Admiralty.

The community at large, however, exercised their discretion in the employment of the new or the old weights and measures, till, in July 1837, the government of Louis Philippe passed a law by which the adoption of the system was made compulsory, though the regulation was not to take effect till January 1840. No difficulty was found in carrying out the provisions of this law. The French people have accommodated themselves to the change, and, according to the testimony of M. Chevalier (*Parliamentary Report* 411, 1862, p. 60), the metrical system has given universal satisfaction, and has simplified commercial transactions to the fullest extent that could have been anticipated. The machinery by which the system was enforced was very easy. The *Vérificateur des Poids et Mesures* visits the shops in his *arrondissement*, and inspects the weights for the benefit of the customers. This official is instructed to inhibit all but metrical measures; and as the transfer of land is registered in France, and must be transacted before a *notaire*, this person is forbidden to use any other than the divisions of the *are*.

The basis of the decimal system in France is the *mètre*. This measure of length is equal to the estimated ten-millionth part of the distance between the north pole and the equator, the calculation having been taken from the measurement of an arc of the meridian, comprised between Dunkirk and Barcelona, and the result being reduced precisely. The *mètre* is rather more than the English yard, 100 *mètres* being equal to 119·6046 yards.

The superficial measure is the *are*, which is equal to the square of ten *mètres*; the solid measure is the *stère*, that is the cube

DECIMAL SYSTEM

mètre; the liquid or dry measure, the litre, i.e. the cube of the tenth part of a mètre; while the unit of weight is the gramme, i.e. the cube of the hundredth part of a mètre of pure water at the temperature of 32° Fahrenheit, or 0 centigrade.

The multiples and divisors of these quantities are decimal, the former being taken from the Greek, the latter from the Latin. Thus deca, hecto, kilo, myriagramme represent respectively 10, 100, 1,000, 10,000 grammes; while deci, centi, milligramme, are respectively, .1 .01, .001 parts of a gramme.

The following are the several weights and measures reduced to English values:—

Gramme . . .	15.4327 grains.
Mètre . . .	39.3709 inches.
Litre . . .	1.7608 pints.
Are . . .	119.6046 square yards.
Stère . . .	1.308842 cubic yards.

The decimal system is beyond question an economy of time in calculation. Beginning with a unit of *low* quantity, its adaptation to the easy determination of weights, both of great and small amount, has caused it to be adopted in quantitative analysis, and in some commercial transactions. Besides, as it is derived from a natural fact, it could be adopted by all nations without wounding national vanity; and it is superfluous to argue that a uniform international system of weights and measures would be of the greatest possible benefit, both as an economy and as enlarging and solidifying commercial relations between communities. Nor are the practical difficulties of real importance, for the experience of the system in France is conclusive as to the readiness with which the advantages of the decimal method are recognised and accepted.

But there are considerable difficulties in the adaptation of the decimal system to an international currency. Of the advantages which such a currency would confer, there can indeed be but one opinion; and ultimately the interests of nations and the progress of commercial diplomacy may perhaps induce the change; but it will be necessary first that the measure of value should be taken in the same metal. At present the standard in England and some Continental states is gold; in France and the majority of European communities it is silver. Next, the unit must be small or of low value. If it be large, as the subdivisions under the decimal system become fractional after the first division, the system would be more cumbersome and inconvenient than the custom which it is intended to obviate—a custom which is partly decimal, partly duodecimal.

It has been suggested that the sovereign should be divided into a thousand mills, the florin representing 100, and so on. This appears to be the best means for carrying out the decimal system in the United Kingdom, but it does not meet the larger and ultimately more important question of an international currency.

For the fullest information on this question,

DECLINATION

see the 'Report on Weights and Measures,' *Parliamentary Papers* 411, session 1861-2.

The decimal system is adopted in France, Belgium, Holland, Italy, Spain, Portugal, Switzerland, Greece, many countries in South America, and is slowly finding its way into Sweden and Russia.

Decimation (Lat. *decimatio*). In Roman History, the selection by lot of one man out of every ten, who was put to death as an example to, or satisfaction for, the rest, in cases of mutiny or failure in military duty. This practice has been occasionally resorted to in modern times; as by the Spanish general Cuesta, after the battle of Talavera.

Deck (Ger. *decke*, a covering, and *dach*, a roof). On Shipboard, a platform of planks laid upon the beams and carlings, forming a flooring for those above and shelter for those below. In addition, it is the support of guns, cargo, &c., and, when the hatches are battened down, the means of keeping the waves out in tempestuous weather. To make them watertight, the planks are caulked and pitched between. In large vessels there are several decks, as the *upper, main, lower, and orlop* decks.

Declamation (Lat. *declamatio*). Signified, among the ancients, the art of speaking indifferently upon both sides of a question. In modern times the meaning of *declamation* is different in different countries. In Germany, and in most parts of the Continent, it is often used in a sense nearly synonymous with *recitative*. In France and England, especially in the latter, it is sometimes applied to any grand oratorical display, either in the pulpit, at the bar, in the senate, or on the stage. But it is employed most usually in a disparaging sense, to indicate the use of forced emphasis and inflated language to withdraw the attention of the hearer from the weakness or fallacy of the reasoning. [ELOCUTION.]

Declaration (Lat. *declaratio*). In Law, a legal specification, on record, of the cause of action, by a plaintiff against a defendant. [PLEADING.]

Declaration, Dying. In English Law, an exception to the rule that hearsay evidence is not admissible [EVIDENCE], is admitted in the case of homicide; where the declaration made by a person in immediate expectation of death as to the circumstances of his mortal injury is received, although he cannot be present to give evidence in court.

Declension (Lat. *declinatio*, from *declino*, I deflect). In Grammar, the changes of termination in nouns, corresponding to the various relations in which substances are conceived to stand. [CASE and GRAMMAR.]

Declination of a Celestial Body. The angular distance of the body north or south from the celestial equator. It is measured on the great circle which passes through the centre of the body and the two poles of the heavens, and is consequently perpendicular to the equator; or it may be defined to be the arc of a circle of declination, passing through the place of the

DECLINATION CIRCLES

heavenly body, intercepted between that place and the celestial equator. The place of a star in the heavens is determined by means of its *right ascension* and *declination*; the *right ascension* being the angular distance, measured on the equator, between the first point of Aries and the point in which the circle of declination of the star intersects the equator, measuring from the first point of Aries eastward, or in the direction of the earth's motion round the sun. Right ascension and declination thus correspond to longitude and latitude on the surface of the earth. In the analytical theory of the planets it is often necessary to define the place of a planet or comet with reference to the ecliptic, or plane of the earth's annual motion; and the early astronomers unfortunately adopted for this purpose the terms *longitude* and *latitude*, which, as the same terms are appropriated to terrestrial objects in a different sense, is the cause of considerable embarrassment to beginners. The student of astronomy must therefore remember that in speaking of celestial objects, *declination* and *right ascension* have reference to the *equinoctial*, or plane of the earth's diurnal rotation, while *latitude* and *longitude* are measured respectively from and along the *ecliptic*.

The declination of a star is said to be *north* when the star is north of the equator, and *south* when the star is south of the equator.

Declination Circles. Great circles passing through the poles of the heavens. Parallel of declination are small circles parallel to the celestial equator.

Declination of the Magnetic Needle. The axis of a magnetic needle, that is, the straight line which joins its poles, does not coincide with the astronomical meridian, but deviates from it more or less, sometimes towards the west and sometimes towards the east. This deviation is called the *Declination of the Needle*.

The following table of observations, made at Paris, will be sufficient to give an idea of the changes which the declination of the needle has undergone at different epochs:—

Years	Declination	Years	Declination
1580	11° 30' East.	1814	22° 34' West.
1618	8 0	1817	22 19
1663	0 0	1819	22 29
1678	1 30 West.	1822	22 11
1700	8 10	1824	22 23
1767	19 16	1825	22 22
1780	19 55	1832	22 3
1785	22 0	1843	21 25
1805	22 5	1852	20 20
1813	22 28		

From this table it appears that since 1580 the declination has varied more than thirty degrees. In 1663 it vanished. From the date of the first observations till 1820, it has advanced progressively westward; but since that time it has

DECOMPOSITION, CHEMICAL.

assumed a retrograde movement towards the east. (Pouillet, *Éléments de Physique*, t. i. p. 462.)

The declination of the magnetic needle at London in 1866 was 20° 30'. [MAGNETISM.]

Declinometer. An apparatus for measuring the declination of the magnetic needle, or the force of terrestrial magnetism in the plane of the horizon. [MAGNETOMETER.]

Decoits or Dacoos. In Hindustan, the name given to associations of robbers who go about the country in gangs. The occupation is generally hereditary, as with the Thugs, with whom, however, they must not be confounded. [THUGS.]

Decollation (Lat. *de*, and *collum*, the neck). A word synonymous with *beheading*; used chiefly in reference to the decapitation of John the Baptist. This word is used by Fabyan so far back as the year 1350.

Decomposition, Chemical. When compounds are resolved into their elements, or when the chemical constitution of substances is altered, they are said to be decomposed; and when, in this operation, new products are formed, such products are called the *results of decomposition*. Thus, *ammonia* is the result of the decomposition of certain animal substances; *carburetted hydrogen gas* is the result of the decomposition of pit-coal, &c.

Chemists use the terms *simple* and *compound*, or *single* and *double* decomposition, to distinguish between the less and more complicated cases. When a compound of two substances is decomposed by the intervention of a third, which is itself simple, or which acts as such, the case is one of simple decomposition: water, for instance, is a compound of oxygen and hydrogen. When the metal potassium, which is a simple body, is thrown into it, it is decomposed; the hydrogen is liberated in the form of gas, and the oxygen combines with the potassium to form potassa. Such a case is often tabularly represented as follows; and the annexed numbers are the *equivalents* of the acting bodies, or the respective weights which are required for perfect decomposition:—

This shows that when 9 parts by weight of water are decomposed by 39 parts of potassium, 7 parts of potassa (or oxide of potassium) are formed, and 1 part of hydrogen liberated.

When two new compounds are produced, the result is called *double* or *complex* decomposition. Thus, when potassa (composed of potassium and oxygen) and hydrochloric acid (composed of hydrogen and chlorine) react upon each other, chloride of potassium (composed of chlorine and potassium) and water (composed of hydrogen and oxygen) are the results. These, with their respective *equivalents*, are shown in the following diagram:—

DECOMPOSITION OF FORCES

Water 9.

Hydrochloric acid 37.	Hydrogen 1 + oxygen 8.	Potassa 47.
	Chlorine 36 + potassium 39.	

Chloride of potassium 75.

This table, therefore, shows that 37 parts by weight of hydrochloric acid and 47 of potassa produce, by mutual decomposition, 75 parts of chloride of potassium and 9 of water.

A knowledge of the mutual decomposing powers of different substances, or, in other words, of their relative affinities, constitutes the skill of the practical chemist. [AFFINITY; EQUIVALENTS; CHEMISTRY.]

Decomposition of Forces. In Mechanics, is synonymous with *resolution of forces*. [FORCES AND ROTATIONS.]

Decomposition of Light. The separation of a beam of light into the different rays which constitute the prismatic colours. [LIGHT.]

Decoration (Lat. decorare, to adorn). In the Fine Arts, the decoration of any work should be confined strictly to the development of impressions which the mass itself is intended to create in strict accordance with its use; its object being merely to present new images which spring from the original bare design. All decoration or ornament must be accessory, never principal, or overloading its object. The ornaments chosen should be in absolute æsthetic accordance with the object adorned; for example, a vessel which is designed to hold liquid should never be so ornamented as to represent basket-work, which is æsthetically antagonistic in its suggestion to the use of the object decorated. [ORNAMENT.]

Decoy. A device by which aquatic birds, chiefly ducks, are enticed from a river or lake, up a narrow winding canal or ditch, which, gradually becoming narrower, at last terminates under a cover of network of several yards in length. The birds are enticed by the smoothness of the turf on the margin of the canal, which tempts them to leave the water, and begin to dress their plumage. When so engaged at some distance up the canal, they are suddenly surprised by the decoy man and his dogs, who have been concealed behind a fence of reeds; and having again taken the water, they are driven up by the dogs till they enter within the network which terminates the decoy, and are then readily caught.

Decree, Decretals (Lat. decretum). Decrets or decrees in the Civil Law, are the decisions of emperors on cases submitted to them, forming a part of their constitutions. Decretals were the decrees of popes, having the same authority in canon law as decrees in civil. They retained this authority in most Catholic countries until the fourteenth century. The first authentic decretal was issued by Pope Siricius, A. D. 385: it prohibited the marriage of priests and deacons. But during the pontificate of Nicolas I. there suddenly appeared fifty-nine

DEDICATION

letters and decrees of the twenty oldest popes from Clement to Melchisedes. This spurious collection, which contained the Donation of Constantine, with thirty-nine false decrees, and the acts of several unauthentic councils, introduced among the decrees of popes and councils from Silvester to Gregory II., asserted the absolute supremacy of the popes, and maintained the whole Romish system of dogma and disciplina. The authorship of this fraud is not known; but the date of their appearance can be determined within a few years. They were certainly completed after A. D. 829, and were not less certainly published before A. D. 847. (Milman, *History of Latin Christianity*.)

Decree. In Law, the judgment of a court of equity on any bill preferred. Either party may petition the court for a re-hearing before it is signed and enrolled. After that form has been gone through, a bill of review may be had upon apparent error in judgment on the face of the decree. It may also be appealed against in the House of Lords. In Scottish law, various legal judgments and sentences are styled *decreets*.

Decrement (Lat. decrementum). The part by which a variable quantity is conceived to be diminished. It is opposed to *increment*, a term of frequent use in the differential calculus.

Decrepitation (Lat. crepito, I crackle). The crackling noise which common salt and many other substances make when thrown into the fire. It is generally occasioned by the conversion into vapour of small portions of water imprisoned in the interstices of the substance, the latter being torn to pieces by the expansive force of the vapour so generated.

Decurio. The Latin name for the commander of ten men. A military decurion was a cavalry officer, who originally commanded ten soldiers, or one-third of a turma; but afterwards the same name was preserved, though the command was extended to the whole turma. Municipal decurions were magistrates in the municipal towns, answering to senators at Rome. In later times also certain officers of the imperial household used this title: as decurions of the chamberlains, &c.

Decussate (Lat. decussatus, crossed). Applied to the arrangement of bodies in pairs that alternately cross each other; as the leaves of many plants.

Dedication (Lat. dedicatio). In Literature, a complimentary address to a particular person, prefixed by an author to his work. The custom of dedicating works was in use at a very early period. Horace, Virgil, Cicero, and Lucretius were among the number of those who practised it. At the period of the revival of letters in Europe, few works were published without dedications. Many of these dedications are remarkable for their elegance and purity of style, and from the matter which they contain are of more value than the treatises to which they are prefixed. But the practice became gradually perverted; and many of the authors of the succeeding generations

employed them chiefly with the view of securing the patronage of the great. Dedications were most abused in France under Louis XIV., and in England from 1670 to the accession of George III. Dryden was a great dedicator, and Johnson wrote dedications for money. Corneille got 1,000 louis d'ors for the dedication of *Cinna*. Some of the most beautiful dedications with which we are acquainted are those prefixed to the different volumes of the *Spectator*, by Addison; and in more recent times the poetical dedications with which each canto of Sir Walter Scott's *Marmion* is prefaced. A complete history of dedications would be of great value, as throwing light upon the history and character of many distinguished persons which are now involved in obscurity. A few such works are in existence; but they are only accessible to the learned. (*De Dedica. Lib. vet. Lat.* by Walch, Leipzig 1715; *Commenta. de Dedica. Lib.* by Tacke, Wolfenbüttel 1733.)

Dedimus Potestatem (Lat.). In Law, a writ or commission given to one or more private persons, for the speeding an act appertaining to a judge or some court. When the commission of the peace is renewed, a writ of dedimus potestatem is issued out of chancery, directed to some ancient justice, to swear-in a justice newly inserted.

Deed (A.-Sax. *dæd*, Ger. *that*, a *thing done*). A deed, in Law, is a writing sealed and delivered by the parties. If made by one party only it is termed a *deed poll*; if by several, an *indenture*. The formal parts of a deed of conveyance are, first, the date and names of the parties; secondly, the recitals, in which the intention of the parties and former transactions with reference to the same property are recounted, so far as necessary; then the operative part. This expresses, first, the consideration for which the deed is made (which for many sorts of deeds is now merely nominal); then the conveyance by and to the several parties; then the parcels, or description of the tenements and their legal adjuncts; then what is termed the *habendum*, beginning with the words 'to have and to hold,' expressing the quantity of estate conveyed; then the declaration of uses, which limits or modifies the enjoyment to one or more parties, according to the stipulations previously made; then the declarations of trusts, if any, that is, of equitable interests created in the property; and lastly, the covenants for title. These covenants stand in the place of the ancient warranty, a clause by which the grantor warranted and secured to the grantees the thing granted; arising out of the feudal custom, whereby if a lord had thus warranted a fief, and the tenant was afterwards evicted, the lord was bound to recompense him with another fief of equal value. The covenants relating to the title secure to the grantee a pecuniary compensation for any damage he may suffer contrary to their stipulations. Besides the covenants for title, such as may be demanded by the peculiar circumstances of the case—as in a

lease the covenants for repairing, payment of rent, &c.—covenants in general, when broken, give the covenantee an action for damages against the covenantor; or if he be dead, against his executor or administrators to the extent of his personal property in their hands. Satisfaction may also be obtained by the covenantee out of the real property of a deceased covenantor.

Lastly, the conclusion of a deed contains its execution and date. It must be signed and sealed by the grantor; and also by the grantee, if any engagement or covenant is entered into by him. It is usual for witnesses to attest the deed; but this is not necessary, unless where, a power having been given to be executed by deed, the terms of the power require such attestation. There are several species of deeds; some having effect at common law, others under the Statute of Uses; some creating an estate termed *original* or *primary*; some enlarging, restraining, transferring, or extinguishing estates already created, which are called *secondary* or *derivative*.

Deemster, Dempster or Demster (A.-Sax. *dom*, *judgment* or *doom*). The title of judges in Jersey and in the Isle of Man. In Scotland, the word long since came to designate an officer who had to recite the sentence which had been pronounced by the court; this office is now abolished.

Deer (Gr. *thp*, Ger. *thier*, a *beast*). The English generic name for the ruminating quadrupeds with deciduous horns, or antlers; which appendages form, in fact, the essential character of the genus *Cervus* of Linnaeus. [CORNUA.] Deer are anatomically distinguished from other ruminants by the absence of a gall-bladder.

The species of deer may be primarily divided into two groups, of which one includes those with antlers more or less flattened, the other those with rounded antlers. The elk (*Cervus Alces*, Linn.) is the most characteristic species of the first group, and forms the type of the subgenus *Alces* of modern systems. It equals or exceeds the horse in bulk; has a short body, with a still shorter neck, raised on long stilt-like legs. The muzzle is long, broad, and overhangs the mouth like a square-shaped lapel: it is very muscular, and is of essential service to the animal in detaching the lichens and mosses from the trunks of trees and other places within its easy reach. The long legs of the elk particularly adapt it to the marshy and swampy forests which it chiefly frequents, in the northern parts of both the European and American continents. The antlers of the elk appear first in the form of *dags* or unbranched pointed stems; these are succeeded by a stem or *beam* supporting a few short branches. At five years he puts up antlers in the form of a triangular plate, supported on a pedicle, and notched along the outer margin. Afterwards the bony plate increases in its expanse, and the points between the notches are developed into long branches or *snags*, of which a single antler sometimes sends off as many as fourteen;

DEER

and the pair will then weigh about fifty pounds. The female elk goes with young for rather more than eight months.

The rein-deer (*Cervus Tarandus*) differs from the rest of the genus in the presence of antlers in both sexes, and in the great development of the *brow-antlers*, or branches which extend forwards over the forehead from the base of the beam. The antlers are retained through the winter; and, as it is understood that the brow-antlers are used to detach the frozen snow, which at that season covers the lichens on which the rein-deer feeds, the necessity of the singular exception in favour of the female rein-deer becomes obvious. Her antlers are, however, always smaller than those of the male. The rut takes place in mid-winter, and the period of gestation is about six months: as in most other species of deer, one fawn is produced at a birth. The rein-deer is a native of the most Northern parts of Europe and America. To the Laplander it serves all the ordinary offices of the beast of draught, and supplies him with the nutriment, clothing, and useful implements, which man in more favoured climes obtains from other species of the valuable order of Ruminantia.

The third species of deer which may be referred to the flat-horned group is that which the ancients termed *platyceros*, and which now forms the ornament of the English park; the fallow deer (*Cervus Dama*, Linn.). In the technical language of the hunter, the male fallow deer is called a *buck*, the female a *doe*, and the young a *fawn*. The buck-fawn of the second year, which is characterised by having simple dags, is a *pricket*. In the third year a brow-antler is put forth, and the young buck is termed a *sorel*. In the fourth year he is a *sore*, and the summit of the beam presents a bifid expansion. At the fifth year the expanded summit of the beam is formed, and begins to develope snags, and the fallow deer is then a *buck of the first head*. At each subsequent year the branches of the expanded beam increase in length to a certain period, after which they lose their size and regularity. The period of gestation in the fallow doe is eight months.

Of the species of deer of which the beam of the antler gives a rounded form in section, the red deer (*Cervus Elaphus*) and the roe-buck (*Cervus Capreolus*) are indigenous species.

The male red deer, in the language of 'the noble art of venerie,' is called a *hart*, and the female a *hind*. She goes with young about a week longer than the fallow doe; and brings forth in May a single fawn, rarely two. The young of both sexes are at first styled *calves*. The male differs from that of the fallow deer in putting up at six months a pair of rudimental antlers, in the form of cylindrical knobs, called *bosses*. In the second year they assume the condition of *dags*, and the wearer is called a *brocket*. In the third year two or three branches or *tyces* are developed, and the young deer becomes a *spayed*. In the fourth year the summit of the beam expands into the crown or

DEFEASANCE

surroyal, and the deer is now distinguished by the name of *staggard*. In the fifth year the term *stag* is applied to him in a limited and technical sense. At the sixth year he is a *hart*, and his designation is not afterwards changed; but at this period he is particularly distinguished as a *hart of ten*, and is not considered fair game till his seventh year, when the hart is said to be *palmed* or *crowned*, in reference to the full development of his antlers. The antlers or *attire* are shed very soon after pairing: at this period, when the hart has lost his attire, he retreats to the shadiest or most unfrequented part of his range. New antlers begin to grow very soon after the old ones are shed, and they are completed in the month of August. The skin or *velvet* which protected the vascular periosteum during their growth, now dries, and is rubbed off against trees or any resisting body; this act is technically called *burnishing*. The harts during this period form a peculiar and distinct association. The hinds form another group, and go also into retirement with their calves, to which they attend with a high degree of instinctive maternal solicitude. The *brockets* and the *brockets' sisters* constitute a third association.

The roebuck is the smallest species of European deer; the male is monogamous, and the female brings forth two fawns. In our island they are now confined to the Scottish mountains.

The largest species of round-antlered deer in America is the *Wapiti* (*Cervus Strongyloceros*); that of Asia is the great *Rusa* (*Cervus Hippelaphus*), which is noticed in the writings of Aristotle. In South America there is a singular group of small deer, called *prickets* or *brockets*, the antlers being developed beyond the simple condition of *dags*, such as characterise the brocket age of the red deer.

Defecation (Lat. defecatio, from fax, *trags*). The separation of the dregs and impurities of liquors.

Defamation. [LIBEL.]

Default (Fr. défaut). In Law, is in a general sense the omission of any act which a party ought to do in order to entitle himself to a legal remedy. Such is, for example, non-appearance in court on a day assigned. If a plaintiff in an action make default in appearance, he is non-suited; if a defendant, judgment by default passes against him. Suffering judgment by default is taken for an admission of the contract alleged by the plaintiff.

Defaulter. In Military language, a soldier undergoing punishment by sentence of his commanding officer. All crimes and offences of soldiers are entered in a book, called the *faultier book*.

Defeasance. In Law: 1. A collateral deed, made at the same time with a deed of conveyance, containing conditions on the performance of which the estate created by the deed conveyance may be defeated. 2. A defeasance is a bond, recognisance, or judgment recovered, a condition which when performed defeats a

DEFECTIVE FIFTH

bond, &c. [Bond], contained in or indorsed on the instrument itself.

Defective Fifth. In Music, an interval containing a semitone less than the perfect fifth. It is also called *semitriplets*, and *flat, lesser, false, or diminished fifth*.

Defence of Fortresses. [FORTIFICATION.]

Defence, National. [NATIONAL DEFENCE.]

Defendant. In English Law, the party against whom claim is made in an action or suit. In proceedings at law, the rule is now held to be that, in personal actions *ex contractu*, the action is brought against the person who either expressly or implicitly made the contract; in personal actions *ex delicto*, against the person who either actually committed the injury, or aided or assisted in committing it, or counselled or ordered the party to commit it; or against all or any of them.

Defender of the Faith (Lat. *Fidei Defensor*). A title bestowed by Pope Leo X. on Henry VIII. of England on the publication of his book against Luther. When at the Reformation Henry suppressed all the monasteries and convents in England, the pope deprived him this title; but in the thirty-fifth year of his reign, it was confirmed by parliament, and it has been since constantly assumed by the sovereigns of England.

Deferent (Lat. *defero, I carry away*). In the Ptolemaic system of the universe the planets move in circular orbits, the centres of which are carried round in the circumference of other circles. These secondary circles are called the *deferents*, as carrying the orbits; those in which the planets move being the epicycles. The system of epicycles and deferents was invented by Hipparchus for the purpose of explaining the eccentricities, perigees, and apogees of the planets. [EPICYCLE.]

Deficient Number. In Arithmetic, is one which exceeds the sum of its aliquot parts. Thus 8 is a deficient number, since the sum of its aliquot parts 1, 2, 4, only amounts to 7. A deficient number is opposed to an *abundant number* in this respect.

Defilading. In Fortification, is (1) so arranging the height of a work that the enemy cannot see into it, or (2) so directing its faces that the enemy cannot enfilade them, or take them in reverse.

Defile (Lat. *flum, a thread*). In Military language, a narrow way, through which troops can pass only in *file*, or a small number abreast, and to *defile* is to pass an obstacle by reducing the front of the troops.

Definite Integral. Denotes the sum of a series of infinitesimal elements, whose first and last terms are given. If $f(x) dx$ be the general type of such an element, the sum of all such, as x increases from a to b , would be the

definite integral represented by $\int_a^b f(x) dx$, of

which a and b are said to be the *limits*. A definite integral is a function of its limits, and of the constants contained in its element-function

DEFTER-DAR

$f(x)$, but does not in any way involve the variable x . In fact, if $F(x) + C$, where C is an arbitrary constant, be the function, whose differential is $f(x) dx$, then in general

$$\int f(x) dx = F(b) - F(a),$$

or as it is often written $[F(x)]^b_a$. The function $F(x)$ is termed the *indefinite integral*, and is usually indicated by the symbol

$$\int f(x) dx, \text{ or } d^{-1} [f(x) dx],$$

the latter being the notation employed in the calculus of operations.

Definite Proportionals. In Chemistry. [ATOMIC THEORY AND EQUIVALENTS.]

Definition (Lat. *definitio*). Literally, laying down a boundary. In Logic, it signifies a description which separates a term from everything else. By the schoolmen definitions were divided into *nominal* and *real*; the former setting forth the meaning of a word, the latter explaining the nature of a thing. There is also a division into *accidental* and *essential* definitions, the former describing by attributes, not included in the connotation; the latter by specifying the *genus* and *differentia*. Such definitions, Mr. Mill remarks, are always liable to be overthrown by the discovery of new objects in nature.

Deflagration (Lat. *deflagratio, a burning*). A chemical term applied to sudden and rapid combustion: when a mixture of charcoal and nitre is thrown into a red-hot crucible, it burns with a kind of explosion, or *deflagrates*.

Deflection (Lat. *deflexio, a bending downwards*). The change of form produced in a beam when its upper surface becomes depressed below its original level line, whether caused by an extraneous weight, or merely by that of the unsupported portion of the beam itself. The laws which regulate the deflection of beams have been thus stated by Coulomb: 1. The deflection below the natural level is proportional to the weight; 2. The weight required to produce depression is proportional to the width of the bar, but in the ratio of the cube of the depth; 3. It is in the inverse ratio of the cube of the length.

Deflection of a Projectile at any point of its flight, is its perpendicular distance, measured horizontally at that point, from a vertical plane passing through the prolongation of the axis of the piece from which it is fired.

Deflection of the Rays of Light. When a luminous ray passes very near an opaque body, it is *deflected*, or bent from its rectilinear course, towards the surface of the body, and the deflection is greater as the distance of the ray from the body is less. To this phenomenon, first observed by Grimaldi, Newton gave the name of *diffraction*.

Deforcement. In Law, a general name for the injury occasioned by the holding of lands or tenements to which another has a right, of property or possession. [INTRUSION.]

Defter-dar (literally, *book-keeper*). The title given by the Turks to the chancellor of

DEGLUTITION

the-exchequer and his two coadjutors or deputies in the finance department.

Deglutition (Lat. *deglutio, I swallow*). In Physiology, the act of swallowing food. This operation is performed by mechanism of the most extraordinary and complicated kind, in which the consentaneous actions of the various muscles of the tongue, the soft palate, the pharynx, the larynx, and the œsophagus or gullet, are concerned, partly by voluntary and partly by involuntary impulse.

There are, as it were, four openings at the back part of the mouth, three of which, during deglutition, must be perfectly but temporarily closed; whilst the fourth, namely, that through which the food is to pass towards the stomach, must be open and without impediment. The openings which are to be closed are those which communicate with the nose, with the ears, and with the lungs; but, as far as the latter is concerned, it follows of course that respiration can only be suspended for a very short time, and that therefore the morsel is swallowed, or has passed over the larynx, the communication between it and the nose must again be free.

When food is properly masticated, a sufficient quantity is collected upon the tongue, which is then so pressed against the palate by a muscular action proceeding from the tip of the tongue backwards, as to propel it towards the pharynx, or upper end of the gullet; at this moment the soft palate, previously hanging like a pendulous veil at the back of the mouth, is drawn into a horizontal position, so as to form a continuation, as it were, of the bony part of the palate, and at the same time to close the nasal canals. As soon as the morsel or portion to be swallowed reaches the pharynx, the base of the tongue, the os hyoides, and the larynx are raised forward to meet it, and hurry it over the opening of the glottis towards the œsophagus. The instant the larynx is raised, the glottis is firmly closed; and as soon as the morsel has passed over it the larynx descends, the epiglottis is raised, and the glottis opens again to allow air to enter the lungs. Thus it is, therefore, that the food is limited to the direction of the œsophagus, and neither passes into the nasal canals, nor into the Eustachian tubes, nor into the larynx, all the concurrent actions in this period of the act of deglutition being simultaneously and involuntarily performed. By the contraction of the pharynx the morsel is delivered into the œsophagus, and propelled by the muscular structure of that tube towards the stomach. In the upper part of the œsophagus, the fibres relax immediately after the passing of the food, but the inferior portion remains contracted for some moments after the food has entered the stomach.

The due admixture of saliva with the food, and the lubrication of the various and complicated parts over and through which the food passes, by mucous secretion, tend materially to facilitate the progress of the alimentary p^{ro}cess.

DEGREE

Degradation (Lat. *de, from, and gradus, a step*). In Law, the act by which any person is deprived of a dignity or degree of honour. In the case of ecclesiastics, it is generally accompanied by the ceremony of taking away, one by one, their sacerdotal robes or ornaments, as in the case of Archbishop Cranmer. With knights, their spurs were hewn off their heels, and their swords broken over their heads.

Degree (Fr. *degré*, Lat. *gradus, a step*). A distinction of rank in universities: in its proper use denoting a certain amount of proficiency in the faculty or science of which it is entitled; but, by modern usage, frequently conferred as an honorary distinction. The origin of degrees at the universities of Paris and Bologna, the two most ancient in Europe, appears to have been only the necessary distinction between those who taught and those who learnt. The former were styled (such was at least the case at Paris) *doctors* or teachers, and *masters*, as a token of respect, indiscriminately. At what time the distinction between these two degrees arose we cannot ascertain; but about the middle of the thirteenth century we find, at Paris, doctors and masters simply as graduates, and not necessarily connected with the business of teaching; those who were so, being called *regent masters*, or simply *regents*. [REGENT.] The degree of bachelor, the lowest in the several faculties, is certainly of French origin; whence it has been argued that the whole system of academical titles is so likewise. Degrees still continue to bear the same names, and, with some variation, the same relative academical rank, in most European countries; but the mode of granting them, and their value at different universities as tokens of proficiency, vary greatly. Honorary degrees, in the English universities, are generally conferred in civil law.

DEGREE. In Algebra, the magnitude of the greatest sum that can be formed by adding together the exponents of the facients or variables which occur in any single term of an equation or expression. Thus

$a^2x^2 + b^2y^2 + c^2z^2 + 2bcxy + 2cax + 2abxy$ is said to be of the second degree in the variables x and y , and it is also said to be of the second degree in the coefficients a, b, c . The terms *degree* and *order* are frequently used synonymously in algebra, but have distinct meanings when applied to *differential equations*.

DEGREE. In Trigonometry, is the angle subtended at the centre of any circle by an arc equal to the 360th part of its circumference, in other words it is the 90th part of a right angle. A degree is subdivided into 60 minutes, and each minute into 60 seconds. The notation employed for an angle of six degrees fifty-two minutes and sixteen seconds is $6^\circ 52' 16''$. The above division of the circle is of very remote origin. It is not certainly known what gave occasion to the adoption of the arbitrary number 360; but it most probably had reference to the space described by the sun in one day in performing his annual revolution in the ecliptic, the number 360 being taken instead of 365, as being more

DEGREE

convenient for arithmetical operations on account of its containing a great number of divisors. The Chinese divide the circle into $365\frac{1}{4}$ equal parts; so that the sun describes daily an arc of one Chinese degree. An attempt was made by the French philosophers, at the period of the Revolution, to introduce into works of science a division of the circle better adapted to our decimal arithmetic (the quadrant, or right angle being divided into 100 degrees, the degrees into 100 minutes, and so on); but though the system was adopted by some writers of the first order of merit (for example, Laplace in the *Mécanique Céleste*), and extensive tables were computed for the purposes of astronomical calculation, it never came into general use, and now appears to be entirely abandoned. It may be remarked, that a division of this sort was recommended long ago by some of the most eminent mathematicians, Stevinus, Wallis, Briggs, Gellibrand, Newton, and others.

DEGREE. In Grammar. [COMPARISON.]

Degree of Latitude. On the surface of the earth, is the distance an observer must advance along the meridian, to the north, or south, in order to produce a variation of one degree in the altitude of the pole. Ever since it was discovered that the earth is round, the exact measurement of a degree of the terrestrial meridian has been a problem of extraordinary interest, inasmuch as it leads directly to a knowledge of the earth's dimensions. In modern times the problem has acquired a still greater importance, in consequence of the discovery of the earth's ellipticity; for it is by the comparison of the lengths of meridional degrees at different latitudes that we are enabled to ascertain accurately the true figure of the earth, which enters as an element into many of the most interesting enquiries of physical astronomy and terrestrial physics.

When we consider the great irregularities of the actual surface of the earth, and that the length of a degree depends on the radius of the circle on which it is measured, it will readily appear that terrestrial degrees at different places, if measured on the external surface, must be exceedingly unequal. In order to obviate the effects of superficial irregularities, and to reduce all the degrees to the same radius, the surface of the sea is supposed to be continued all round under the continents, and it is to this surface or level that all the measurements must be referred. This being understood, the general principle on which the measurement of degrees of the terrestrial meridian must be accomplished are readily perceived. Two stations being assumed on the same, or nearly the same, meridian, the distance between them must be found with great exactness in feet, yards, or some known linear measure. Having ascertained the itinerary distance, the latitude of each of the stations must be determined; the difference of the two latitudes is the length of the celestial arc intercepted between the two stations; and by comparing this with the terrestrial measure, the number of

DEGREE OF LATITUDE

yards or feet corresponding to a degree becomes known. It is evident that, in order to obtain a result of any value, all these operations must be executed with the greatest care and precision. An error of a single second in the celestial arc corresponds to about 100 feet on the ground, and a long series of astronomical observations must be made to obtain the latitude of any place true to a second. On this account it is necessary to measure an arc of considerable length, two or three degrees at least; because the error in the determination of the latitudes is the same, whether the arc be long or short, and in the case of a long arc its influence becomes less sensible. But the exact measurement of a line extending two or three degrees on the surface of the earth, by the direct application of rods or chains, is perhaps altogether impracticable, on account of the irregularities of the ground and many other circumstances which render an operation of this sort, when carried on even for a few miles, an affair of great difficulty. Hence it becomes necessary to have recourse to other methods. A level piece of ground is selected near the meridional arc proposed to be measured. On this a straight line A B is traced, in any direction, and its length H accurately found by the application of rods of

metal, or sometimes of wood or of glass. The ground adjoining the arc to be measured is then formed into triangles by means of signals, C, D, E, F, G, H, K, erected at convenient distances, or on remarkable points of the country; and the angles which the signals make with each other determined by a theodolite or other appropriate instrument. The sides A C and B C are then deduced from the measured base A B, and thence successively the sides of the other triangles. In this manner the whole distance between the stations which form the terminal points of the arc is determined by a series of trigonometrical calculations. The reductions for differences in the levels of the signals must next be applied, and also for their altitude above the level of the sea; and it is obvious that these reductions cannot be made without having at least an approximate knowledge of the dimensions of the earth, and without making some hypothesis respecting its figure, though the dimensions and figure of the earth are elements that can only be deduced from the measurement and comparison of degrees.

From this general description it will be readily inferred that the measurement of terrestrial degrees depends on astronomical operations of very great nicety, on most careful triangulations, and the exact measurement of a base line. To such perfection have we now arrived, that the greatest possible error in the base line on which the correctness of our own Ordnance Survey depends—a line between seven and eight miles long—is supposed not to exceed two inches!

DEGREE OF LATITUDE

In the year 1735, the Academy of Sciences of Paris, to decide the important question of the spheroidal form of the earth, resolved that two arcs of meridian, the one at the equator and the other as near the pole as possible, should be measured with all the accuracy which the improved state of astronomy admitted of. Accordingly, Bouguer, Godin, and Condaminé were despatched to Peru; Maupertuis, Clairaut, Lemonnier, and some other associates, to Lapland—for the execution of this purpose. The latter party accomplished their mission, and returned to Paris within sixteen months; Bouguer and his companions had to contend with great difficulties and hardships, and were detained not less than ten years. The result was that the length of the degree of the meridian at the equator, reduced to the level of the sea, was found to be 56,753 toises, or 362,912 English feet; and in Lapland, under the parallel of $65\frac{1}{2}^{\circ}$, to be 57,437 toises, or 367,286 feet, exceeding the former by 684 toises.

Since these memorable expeditions, several arcs of meridian have been measured in different countries, and all the results concur in proving that the degrees increase in length as we proceed from the equator to the pole, agreeably to the theory of hydrostatic equilibrium, which requires an accumulation of matter in the equatorial regions of the earth, in order to counterbalance, by its attraction, the effect of the centrifugal force of rotation.

The following are the most important of these measurements:—

No.	Meridional Arc	Amplitude or Length of Arc	Latitude of Middle Point	Length of Degree in English Feet
1	Arc measured by Bouguer, recomputed by Delambre	0 0 0	0 0 0	362,809
2	First Arc measured in India by Col. Lambton, from Trivandeporum to Paudree	1 34 56	13 33 21 N	362,988
3	Second Indian Arc by Col. Lambton and Capt. Everest, from Punnée to Nullampoor	15 57 39	16 8 23	363,040
4	French Arc from Dunkirk to Formentera by Méchain and Delambre	12 23 13	44 51 0	364,644
5	English Arc from Dunnose to Burleigh Moor	3 57 13	53 35 45	365,083
6	Arc measured in Hanover by Gauss, from Göttingen to Altona	2 0 57	53 23 17	365,201
7	Arc measured in Lithuania by Struve, from Jacobstadt to Hookland	3 35 5	58 17 37	365,277
8	Arc measured in Sweden by Svanberg, from Malmö to Fahlarna	1 37 20	66 20 11	365,697

More recent measurements in India have been executed by Sir George Everest with extraordinary care, and with instruments sufficient to insure the utmost attainable accuracy. Three base lines, each exceeding seven miles in length, were measured with a compensating apparatus similar to that invented and used by General Colby for the measurement of the base of the trigonometrical survey of Ireland. The terrestrial angles were observed with theodolites of three feet in diameter, and the two celestial arcs were determined by observations of stars made simultaneously at both extremities of each arc with altitude and azimuth circles, having vertical circles also of three feet in diameter. The final results were as follows: The amplitude of the celestial arc corresponding to the northern section, Kaliana to Kalianpur, was found by the mean of all the observations to be $5^{\circ} 23' 37\cdot051''$; and that of the southern, Kalianpur to Damargida, $6^{\circ} 3' 55\cdot973''$. The terrestrial distances on the meridian, computed from the mean of the two bases (near the extremities of each section), and reduced to the level of the sea, were 1,961,157·117 feet and 2,202,926·196 feet respectively. Hence the length of the meridional degree, as found from the northern section, is 363,606 feet, or 68·865 miles, at the middle latitude $26^{\circ} 49'$, and as found from the southern section is 363,187 feet, or 68·785 miles, at the mean latitude $21^{\circ} 5'$. The comparison of the two arcs, without reference to other measures, gives an ellipticity to the terrestrial spheroid of $1+192$, considerably greater than the ellipticity deduced from the results (properly combined) of all the principal operations of the same kind executed in different countries, namely $1+300$, and consequently indicating some irregularity either in the curvature of the earth at that locality, or in the density of the superficial strata, giving rise to local attraction at the terminal stations.

The 29th vol. of the *Memoirs of the Royal Astronomical Society* contains an important paper by Captain Clarke, in which all the most important geodesical measurements are examined. The final result, as given in Sir John Herschel's *Astronomy*, 7th edition, is as follows:—

The earth is not exactly an ellipsoid of revolution. The equator itself is slightly elliptic, the longer and shorter diameters being respectively 41,862,864 and 41,842,096 feet. The ellipticity of the equatorial circumference is therefore $\frac{1}{4283}$, and the excess of its longer over its shorter diameter about two miles. The vertices of the longer diameter are situated in longitudes $14^{\circ} 23'$ E. and $194^{\circ} 23'$ E. of Greenwich, and of its shorter in $104^{\circ} 23'$ and $284^{\circ} 23'$ E. The polar axis of the earth is 41,707,796 feet in length, and consequently the most elliptic meridian (that of longitude $14^{\circ} 23'$ and $194^{\circ} 23'$) for its ellipticity $\frac{1}{287\cdot5}$, and the least so (that

DEGREE OF LONGITUDE

of longitude $104^{\circ} 23'$ and $284^{\circ} 23'$ an ellipticity of $\frac{1}{308.3}$.

The following table shows the length of a degree of latitude at every tenth degree:—

Latitude	Length of Degree in English Feet	Latitude	Length of Degree in English Feet
0	362,734	50	364,862
10	362,843	60	365,454
20	363,158	70	366,987
30	363,641	80	368,282
40	364,233	90	368,361

Degree of Longitude. On the earth, a degree of longitude is a degree of the equator, or of any of its parallel circles. If the earth is a regular spheroid of revolution, the circles parallel to the equator, and consequently the degrees of those circles, must diminish regularly as their distance from the equator increases, according to a law derived from the nature of the ellipse. Hence, if we know the measured lengths of a degree of two or more small circles in different latitudes, we are in possession of data sufficient to determine the diameters and ellipticity of the earth. The measurement of degrees of longitude, therefore, in reference to the determination of the earth's figure, is of equal importance with the measurement of degrees of the meridian, and has accordingly been executed in various instances. The geodetical operations required in the one case are the same as in the other; but on account of the great difficulty of determining the astronomical longitudes with the necessary accuracy, the results have never been regarded as equally satisfactory. At the present moment an arc of longitude embracing nearly 70° is being measured between Valentia in Ireland, and Orsk in Russia. This is far in advance of anything previously accomplished, and the rapid extension of telegraphic communication may soon enable us to eclipse even this splendid conception. The following table shows the length of a degree of longitude at every tenth degree of latitude:—

Degree of Longitude in English Feet	Degree of Longitude in English Feet
0	365,152
10	366,040
20	367,263
30	368,493
	369,108
50	375,171
60	383,039
70	395,264
80	412,612
	0

In Music, the small intervals of which the concords or harmonical intervals are composed.

Dehiscent (Lat. *dehisco*, *I gape*). In Botany, a term applied to those fruits which separate regularly round their axes, either wholly or partially, into several pieces. The act of thus splitting is called *dehiscence*.

Dei Gratia (*by the grace of God*). A Latin formula, usually inserted in the ceremonial

DELEGATES, COURT OF

description of the title of a sovereign. It was used originally by the clergy.

Deiscation. [APOTHEOSIS.]

Delioptila (Gr. *deila*, evening, and *philein*, *I love*). A subgenus of hawk-moths (*Sphinxidae*) belonging to the crepuscular or evening tribe of Lepidopterous insects. They are characterised by wings entire and acute: antlia rather elongated; antennae short, and clubbed in the male. One species, *Deil. Celerio*, feeds upon the vine.

Deinotherium (Gr. *deinós*, terrible, and *thērion*, beast). The name of a fossil genus of gigantic Pachyderms, chiefly remarkable on account of its enormous tusks, which projected downwards from the lower jaw instead of the upper, as in the elephant and walrus.

Deism or **Theism** (Lat. *Deus*, Gr. *θεός*, God). Belief in the existence and attributes of God, coupled with disbelief in any express revelation of His will. There exist various shades of opinion among Deists, which are pointed out in Clarke's work on the *Attributes*; but general usage has assigned this word a meaning synonymous with *agnostic* or *free-thinker*: hence it is regarded as a term of reproach. In its original acceptation, *theist* was directly opposed in meaning to *atheist*; but these terms are now frequently, though incorrectly, employed without distinction to designate an *unbeliever in Christianity*.

Déjeuner (Fr. *breakfast*, from Lat. *de*, and *jejunium*, *abstinence from food*). A term naturalised in almost all the languages of modern Europe, signifying the morning meal. It may be remarked, however, that in France itself this term is rapidly losing, if indeed it has not already lost, its original acceptation, being used as synonymous with the English *luncheon*.

Del Credere Commission. In Mercantile Law, a term derived from the Italian (*credere*, *to trust*), which denotes a commission granted by a merchant to a factor to dispose of goods; the factor, for the consideration of an additional percentage, agreeing to guarantee the solvency of the purchaser. [FACTOR.]

Delabeches (in honour of Sir H. T. de la Bèche). To this genus of *Sterculiaceae* belongs the Bottle-tree of Australia, *D. rupestris*, a tree remarkable for the curious form of its trunk, which is bulged out in the middle in the form of a barrel, and abounds in a mucilaginous or resinous substance, resembling gum tragacanth. The wood is remarkably soft, and a clear jelly is obtained by pouring boiling water upon shavings of it. The leaves are sometimes lance-shaped, sometimes digitate, and the flowers altogether inconspicuous.

Delegates, Court of. Formerly the highest ecclesiastical court of appeal in England: in ordinary cases composed of three common law judges and three civilians; in special cases a fuller commission was sometimes issued. In case of a division of opinion, or where no common law judge was in the majority, a commission of adjuncts was issued. Appeal lay to it from the archiepiscopal

DELEGATION

scopal courts. Its powers are transferred by 2 & 3 Wm. IV. c. 92 to the privy council.

Delegation (Lat. delegatio, from *delego, assign*). In the Civil Law, the act by which a debtor transfers to another person the duty to pay, or a creditor makes over to a third party the right to receive payment.

Delft Ware. A coarse species of porcelain, originally manufactured at Delft in Holland, whence its name.

Delian Problem. [DUPLICATION OF THE CUBE.]

Deliquescence (Lat. *deliquesco, to melt down*). When certain saline substances are exposed to air, and absorb a sufficient quantity of water to moisten or dissolve them, they are said to *deliquesce*.

Delirium Tremens (Lat.). A disease of the brain, resulting from the excessive and protracted use of spirituous liquors; it is therefore almost peculiar to drunkards. It begins with excessive irritability, loss of sleep, frightful dreams and visions, and a multiplicity of the ordinary delusions of insane persons, ending in confirmed and often furious madness. The hands are usually, but not always, tremulous. By careful treatment, and more especially by the judicious use of opium, patients have recovered from this disease; but, for obvious reasons, it is difficult to manage, and subject to relapses. Bleeding should in almost all cases be avoided.

Delitescence (Lat. *delitescere, to lie hid*). In Surgery, when a tumour very suddenly and unexpectedly subsides, it is said to terminate in *delitescence*.

Delphi, Oracle of. So called from Delphi, in Phocis, the most famous of all the oracles of Apollo. At this place certain exhalations, issuing from a cavern, threw all who approached it into convulsions. The responses were delivered by a priestess, called Pythia, who sat upon a tripod placed over the mouth of this cavern, and after having inhaled the vapour, gave utterance to the wished-for predictions, either in verse or prose, which were then interpreted by the priests.

From its favourable position this oracle came to be consulted, not only by the Greeks, but even by the neighbouring nations; and thus the temple was enriched by an incredible number of valuable presents and splendid monuments. Hence this sacred repository became frequently an object of plunder. Still the oracle continued to utter its responses long after the seat of empire had been transferred from Greece to Rome; and it was only when Constantine the Great removed the sacred tripods to adorn the hippodrome of his new city, that the responses ceased to be delivered. [ORACLE.]

Delphin. In Bibliography, a name given to the edition of the Latin classics, prepared and commented upon by thirty-nine of the most famous scholars of the day, at the suggestion of Louis XIV., for the benefit of the young Dauphin (in usum Delphini) under the

DELTA

superintendence of Montausier his governor, and his preceptors Bossuet and Huet.

Delphinia. A vegetable alkaline base, obtained from the seeds of the *Delphinium Staphisagria*, or stavesacre.

Delphinic Acid. [DELPHININ.] A fatty acid obtained by saponification from the oil of the *Delphinus* or porpoise: it has also been termed *phosnic acid*. It exists in the vegetable kingdom in the berries of *Viburnum Opulus*.

Delphinite. A variety of *Epidote* from Dauphiny.

Delphinium. A genus of *Ranunculaceæ* which yields many favourite garden flowers. The seeds of Stavesacre, *D. Staphisagria*, are used for destroying vermin; and an ointment prepared from them is sometimes employed in cases of rheumatism and neuralgia. This plant is an annual, with white-veined palmately divided leaves, and loose racemes of greyish flowers, the upper sepal of which, as in the rest of the genus, is spurred.

Delphinus (Lat.). The *Dolphin*, one of the ancient constellations of the northern hemisphere.

DELPHINUS. This term is restricted in modern Zoology to those species of Cetacea which have teeth in both jaws, all simple, and almost all conical. They are the most carnivorous in proportion to their size. The Linnæan genus *Delphinus* is now subdivided into *Hyperoodon*, of which the great bottle-nose dolphin is the type; *Delphinapterus*, represented by the beluga; *Phocæna*, represented by the common porpoise; and *Delphinus* proper.

Delta. The triangular expanse of mud (resembling the fourth letter of the Greek alphabet, Δ) formed at the mouths of certain rivers. Deltas commence at the point at which waters laden with mud first meet the sea in times long past, and after gradually widening, owing to the mud deposited, have ultimately attained their present dimensions. It is essential to the nature of a delta that the stream should traverse the accumulations it has brought down by many channels, and it is almost a necessity that the fresh water should gradually become more and more sluggish in its movements, and thus leave behind it all, even the finest, of the mud particles it has conveyed from the mountains where the river takes its origin.

Among the largest deltas are those of the Ganges, the Mississippi, the Nile, the Rhône, the Danube, the Po, the Rhine, &c. They occur, also, not only in the sea where fresh water meets the salt water, and is checked in its onward path by the tides, but in lakes, the accumulation protruding as a tongue beyond the point at which the river enters the lake.

The most usual form of delta is that presented in the low flat land at the mouths of the Nile and the Rhine. In some cases the river does not appear to have pushed itself forward beyond the coast line; but in the gulf of Mexico,

DELTOID

where the tides are small, the Mississippi has advanced itself forward far beyond the coast line and protrudes many miles. The Nile has also projected its delta far beyond the original coast line of the Mediterranean.

The actual advance of some of the European deltas can be measured by comparing the existing state of things with historical documents. Thus the Po and Adige form a delta, which for the four centuries from 1,200 to 1,600 advanced at the rate of twenty-five yards a year, but which, owing to changes that then took place, has since advanced at the rate of seventy yards a year.

The delta of the Mississippi actually protruding from the coast line, is not less in area than the whole of Ireland; but the advance is not now more than a mile in a century. The deltas of the Nile and the Rhine have certainly increased enormously within the historic period. The delta of the Ganges is already double that of the Nile, its head commencing 220 miles from the sea, and its base line measuring 200 miles. Islands are formed and destroyed in it with extreme rapidity, some of them many miles in extent having risen into existence within the observation of man. The depth of the mud is at least 400 feet. The delta of the Rhône is also very large and deep.

Deltoïd (Gr. δελτοειδής). Of the shape of the Greek letter *delta*, Δ. The term is used in Anatomy and Botany.

Deluge (Lat. diluvium). In the 1656th year after the creation (according to ordinary chronology), in the 600th year of the life of Noah, and on the 17th day of the second month, the waters began to rise upon the earth. They appear to be represented as swelling upwards by some upheaving force, and descending also in continual rain for forty days and nights. All the mountains 'that were under the whole heaven' were covered; 'all flesh perished that moved on the earth,' with the exception of Noah and his family, and the animals which entered with him into the Ark. The waters remained 150 days; and then 'returned from off the earth continually;' and the Ark rested on Ararat on the seventeenth day of the seventh month; and on the first day of the first month of the following year 'the face of the ground was dry,' but not completely drained of the water for nearly two months longer. Such is a concise abridgement of the account of this catastrophe given in Gen. vii., viii.

The belief in the destruction of mankind by a deluge in the earliest times, and of the escape of one family under circumstances resembling those recorded respecting Noah, is a remarkable feature in the traditions of many nations. The Fo-ki of the Chinese, the Satyavrata of the Indians, Xisuthrus or Seisithrus among the Assyrians, Deucalion and Ogyges among the Greeks—all more or less resemble the patriarch of the book of Genesis: even the Mexicans had their traditional deluge. No such event, however, is noticed in the traditions of the ancient Egyptians.

VOL. I.

DEMAND

The tradition that a deluge or a torrent of water has, at a comparatively recent period of the earth's history, swept over the whole surface of the earth and destroyed previously existing landmarks, was at one time thought to be confirmed by geological investigations. It is now certain that no evidence exists of any such event.

Partial deluges, on the other hand, not only may, but must have occurred; for we have unmistakable proof that many large natural reservoirs have been suddenly tapped, and their contents let loose upon low lands of enormous extent, and it is not impossible that one of these events may have been recent enough to justify the tradition that man was then on the earth, and narrowly escaped destruction.

The marks of a universal deluge, had such an event occurred, must have been evident in the valleys, caverns, and other places into which water would enter, and floating objects would be drifted, but from which an exit was difficult. Such localities contain various accumulations, but the mode in which the deposits occur proves clearly that the action of the water that moved them was not diluvial. Many successive events must have combined before even the latest changes of the earth's surface were brought about, and these changes all seem to have been gradual, and to have involved slow elevation and depression of very large areas.

Demagogue (Gr. δειμαγωγός). One who directs or leads the people in political matters. In its original acceptation it was considered an honourable designation; but it is now almost invariably used in a bad sense. The oldest and most satirical of all portraits of the demagogue is traced by Aristophanes in his play of the *Knights*, in the character of Cleon. (Grote's *History of Greece*, part ii. chap. ix.)

Demand. In Political Economy, that mutual desire for services or utilities which tends toward completion in an act of exchange. Demand is commonly said to be relative to supply, but in reality demand is reciprocal to it. The measure of demand is found in the fluctuations of price or money value, though, in effect, the satisfaction of supply by money applies, as a rule, only to the demand for small articles, and in internal trade. In international trade, goods are exchanged against goods, imports against exports, money being rarely used.

It is the custom for political economists to qualify the term *demand* by the addition of the word *effective*, for it is plain that a strong demand may exist without the power of procuring any desirable object in return. But if it is remembered that all economical theories originate in the interpretation of acts of exchange, it will not be necessary to make the limitation. A mere desire for objects has no economical significance, but that desire only which originally contemplates a reciprocal service or benefit.

The intensity of demand, and its consequent effect on prices or values, will be proportional to the necessity which exists for satisfying the

T T

DEMAND

demand. Hence different rules will apply to the increase of price consequent on enlarged demand or straitened supply in articles of voluntary use, and to the same increase of price when affecting commodities of necessary use. The demand in the latter class of commodities is constant, and a deficiency in supply will not or cannot be met by abstinence, except to a very limited amount, whereas any considerable deficiency in the supply of articles of voluntary use is to some extent obviated by economy. Prices will therefore increase in different ratios according to the degree in which the objects demanded are necessary, convenient, or voluntary.

This law of the increase of price is seen most clearly in the effect of insufficient supply on the price of food. Suppose, for instance, that the amount of corn consumed by a people in average years is represented by ten million quarters; and that from some cause (for example, a wet harvest) the supply falls short of the average consumption by two millions of quarters; and further, that when the supply is commensurate with the ordinary demand, the price is sixty shillings a quarter. The consequence of the scarcity would not be that the eight millions would sell for thirty millions of sovereigns—the price, that is, of ten millions in average years—but for forty, fifty, or sixty millions; for the commodity being a necessary of life, and one which, when abundant, is not used in excess, everything which tends to diminish its quantity provokes a more urgent demand for equal participation in the remainder. It is easy to see, therefore, how important it is that every facility should be given for the supply of food, since the contingency of great fluctuations in the money price of food will be diminished as the area of supply is extended.

The same law applies, in a modified form, to the demand for a great convenience—as, for instance, the raw material of necessary clothing, as cotton and wool. Here a scarcity will not represent so aggravated a rise as ensues from a scarcity of food, but it will be sufficient to enhance the money value of the insufficient quantity to a larger amount than that of the aggregate price of a full supply. A striking example of this will be found in the recent rise in the price of these raw materials; the sole cause, apparently, of the enhanced cost residing in the cessation of supply from the region which contributed one of these commodities in the greatest quantity.

Where, however, the commodity is one of voluntary use, a considerable scarcity may occur without any great increase of price. The vine, for instance, has for several years been affected by a serious disease. But the rise in the price of wine has not been commensurate with the deficiencies of several vintages, and is much more to be assigned, where it has occurred, to increased demand consequent on greater power of expenditure, than to any other cause. On the other hand, the increase in the price of meat has not been consequent upon diminished supply, but on a greatly enlarged demand, the

DEMIDITONE

demand arising from the marked improvement in the condition of some among the operative classes; an improvement partly due to the actual enlargement of their money wages, partly to the remission of taxation, and much more to the low price of bread consequent upon the results of free trade in corn.

It is necessary to observe that demand may exist very urgently, and yet supply be not forthcoming. We may demand commodities, but the capital necessary to satisfy that demand by production may not exist, or may not easily be diverted from other occupation. When, however, the spread of sound economical principles has led governments to give all security which law can give and confirm to advances of capital for industrial occupations in communities where capital is scanty or dear, the interval which always must exist between increased demand and supply from new quarters will be proportionately diminished. The fact that very different rates of interest prevail in countries which are geographically near and are politically distant, is a barbarism which indicates municipal jealousy, insufficient legislation, or partial and unfair administration.

Demarcation. A term used to designate the line or boundary by which one object is separated or marked off from another. The word was first introduced in 1493, when Pope Alexander VI., in order to put an end to the disputes between the crowns of Spain and Portugal relative to their Indian discoveries and conquests, by virtue of his pontifical authority drew through the ocean an imaginary line, by which the dominions of both parties were defined; and thus originated the expression *line of demarcation*.

Demeane (Lat. *terra dominicalis*). In Law, originally that portion of the lands belonging to a lord which was held in his own occupation. Hence it is sometimes used to distinguish those parts of a manor which the lord has in his own hands, or those of lessees at rack-rent, from those which are in the hands of freeholders and copyholders. [ANCIENT DEMEANA.]

Demeter (Gr.). This goddess, in the *Theogony* of Hesiod, is a daughter of Cronos and Rhea, and the mother of Persephone [ΠΕΡΣΕΦΩΝΑ] and Dionysus [ΔΙΟΝΥΣΟΣ]. The most prominent myth connected with her name is the rape of Persephone, who is seized by Hades while gathering flowers in the fields of Enna. In the search for her child, Demeter comes to Eleusis in Attica; and the legend thus accounts for the institution of the Eleusinian mysteries. The name Demeter has generally been supposed to be the same as *γῆ μήτηρ*, Mother Earth; but by Professor Max Müller it is connected with the Sanscrit *Dyāvā Mātā*, the Dawn. (*Lectures on Language*, second series, p. 517.)

Deimi (Fr.). A word signifying *half*, frequently used in the composition of English words, being equivalent to the Latin *semi*.

Demiditone (Gr. *ἡμίσητος*). In Music, a minor third. [THIRD.]

DEMIGODS

Demigods. A general appellation of the inferior divinities of Greece and Rome, more particularly of such of the mixed offspring of divinities and mortals as were afterwards deified.

Demiurge. In Fortification. [RAVELIN.]

Demi-quaver and Demisemi-quaver. In Music, notes equal in duration to half a quaver and semiquaver respectively.

Demi-tint. In Painting, a tint representing the mean or medium between light and shade, or the gradation between one tint and another; by some called a *half-tint*.

Demiurgus, Demiurge (Gr. δημιουργός). In the original sense of the word, as used by classical authors, an artificer employed in ordinary handicraft. In the language of Platonist writers, it denotes an exalted and mysterious agent, by whose means God is supposed to have created the universe. Hence the Demiurgus, or Logos, as the same imaginary agent is termed in the *Timæus* of Plato, is identified by the Platonising Christians with the second Person in the Trinity.

Democracy (Gr. δημοκρατία, from δῆμος, *people*, and κρᾶτος, *I govern*). A government is usually termed a democracy in which the whole of the people, or a large proportion of it, exercises sovereignty either directly or by representatives. According to some political writers, the term is strictly appropriate only where 'a majority of the adult males' share in the government. In Aristotle's view of governments, democracy is a perversion of the imaginary system, which he terms Politeia, or commonwealth par excellence; in which the majority are supposed to govern for the good of the whole, while in democracy they govern for their own. [REPUBLIC.]

Demogorgon. In Mythology, a mysterious being, who was an object rather of terror than of worship: hence in the *Paradise Lost* (book ii.) Milton speaks of

the dreaded name

Of Demogorgon.

The Demogorgon is also introduced by Shelley, under a somewhat different aspect, into his drama *Prometheus Unbound*.

Demoiselle (Fr.). In Zoology. [GRUPE.]

De Moivre's Theorem. An important relation discovered by De Moivre (*Miscellanea Analytica*), and expressed by the formula,

$$(\cos \theta + \sqrt{-1} \sin \theta)^n = \cos n(\theta + 2\pi) + \sqrt{-1} \sin n(\theta + 2\pi),$$

where n is any integer. The demonstration is simple, and is given in all treatises on trigonometry. It will be sufficient to add here that the formula is true for all values of n and θ , and that for integral values of n , positive or negative, it assumes the simpler form

$$(\cos \theta + \sqrt{-1} \sin \theta)^n = \cos n\theta + \sqrt{-1} \sin n\theta.$$

When n is fractional, equal to $\frac{p}{q}$, the q different values which the expression on the left then possesses are obtained by giving to n the successive values, $0, 1, 2, \dots, q-1$; every other value of n will give to the expression on the

DEMONOLOGY

right one or other of these q values; thus s being less than q , $r = mq + s$ and $r = s$ will lead to the same result, whatever positive or negative integer m may represent.

Demon. [DEMONOLOGY.]

Demoniacs. Persons possessed by or under the influence of demons or devils. The idea of demoniacal possession was very ancient among the Oriental nations.

Demonology (Gr. δαίμων, and λόγος, *discourse*). The belief in an intermediate race of beings, between deity and humanity, has been a prevalent feature in almost every popular creed; and all tradition or speculation respecting it may be said to fall under the general term of *demonology*. Among the early Oriental nations, especially the Persians and Egyptians, the science of astronomy appears to have been essentially connected with this branch of superstition; the heavenly bodies were honoured as demons or celestial intelligences. This ancient belief appears to have had much influence on the Jewish rabbinical writers; and out of it, connected with what is revealed to us in the Old Testament of the existence and attributes of angels, they framed their peculiar mythology.

The Greek word δαίμων, *demon*, is said to be connected with δαίμων, *knowing* or *intelligent*. In Homer there is scarcely any distinction between gods and demons. A generic difference between them is first brought out in the Hesiodic poem entitled *Works and Days*. In this poem, the men of the golden age have become guardian terrestrial demons, for the benefit of mankind. Those of the silver age are the blest of the under-world, and so not strictly demons at all. But it was easy to treat them as demons of a malignant character; and, as soon as this was done, the fabric of demonology was complete. The Hesiodic heroes are quite different from the demons, being the men who fought before Thebes and Troy, and gave a name to the heroic age. Thales is said to have defined more accurately the difference between gods, heroes, and demons properly so called; and in Plato's theology the demons occupy an important place—as closely watching over, directing, and recording the actions of mortals. By later writers they were divided into many classes: some good, some bad (Agathodæmon, Cacodæmon, from ἀγαθός, *good*, and κακός, *bad*); some ministers of punishment and revenge, some freeing from evils already befallen (ἀλυσίαι), some warding off their approach (ἀλεξίμαχοι), &c. It was in — and Syria, under the Ptolemies and — Jænicæ, that the Grecian philosophy and mythology came in contact with those of the Rabbis; and from that union a new mixed system of demonology took its origin. Hence, in the Greek of the New Testament, the word δαίμων is taken, without addition or qualification, as an evil spirit, and rendered by our translators 'devil.'

Analogous to the demons of the Greeks were the genii of the Romans; but there were

DEMONSTRATION

peculiar and characteristic features about the belief in the latter which show it to be of a different origin, possibly derived from the Etruscans. The *genii* of the Romans were an innumerable host of spirits: every man, house, or city had an attendant genius. The genius of every mortal is mortal as himself; accompanies him into life, and conducts him in all its vicissitudes. In this sense, the *genius* was a benignant companion: to enjoy the good things of life is represented as 'indulging' or gratifying the genius; abstaining from them, as 'defrauding' him. Wine and flowers are appropriate offerings to him. But he is also termed *enſus mutabilis, albus et ater*: he is the companion of the mischances as well as the pleasures of life; unless, as the difficulty appears sometimes to have been solved, the individual had his *pair* of *genii*, good and bad. The Etruscans represented the evil genius as a dark and frightful figure, attending a mortal on one side, who is protected or followed on the other by a child or youth—the usual emblem of the good genius. The genius is often represented on vases and in ancient paintings as a winged figure; and a genius holding a torch downwards is the emblem of death.

The demons of the middle ages were simply fallen angels or devils, according to the sense of the word in the New Testament; and hence demonology, in the language of modern writers, generally signifies the history of the supposed nature and properties of such evil spirits, and of the modern superstition respecting compacts between them and mankind. [MAGIC; WITCHCRAFT.]

Demonstration (Lat. *demonstratio*, from *demonstro*, *I show*). This term was used by the old writers to signify any manner of showing either the connection of a conclusion with its premisses, or that of a phenomenon with the asserted cause; but it now means, in philosophical language, only that process by which a result is shown to be a necessary consequence of the premisses from which it is asserted to follow, on the supposition that those premisses are admitted, either as matter of fact, or of intuitive evidence, or of previous demonstration.

DEMONSTRATION. In Military language, any operation performed with a view to deceive an enemy.

Demos (Gr.). In ancient History, a district or tract of land, probably from *δῆ*, the Doric form of *γῆ*, the earth. The Attic *Demi* answered to our townships or hundreds; their union into one people, with Athens as their centre, is attributed to Theseus. (Thucydides ii. 15; Grote's *History of Greece*, part ii. ch. x.)

Demetic Characters. [HIEROGLYPHS.]

Demulcents (Lat. *demulceo*, *I soothe*). Medicines which sheathe and defend sensible parts from the action of irritating matters; they are chiefly mucilaginous substances, such as gum, starch, &c.

Demurrage. In Mercantile Law, the delay which a merchant makes in loading or unloading a ship, beyond the time specified in his charter-

DENOMINATOR

party, or other agreement with the owners; in which it is usually stipulated that he shall pay at a certain rate per diem for such extra time, which payment is also termed *demurrage*.

Demurrer (from the Lat. *demoror*, *I delay*). In Law, an issue between plaintiff and defendant on matter of law. It confesses that the facts are true as stated by the opposite party, but denies the legal consequences inferred by the opposite party from these facts, thus raising the question of law. [PLEADING.] Demurrers in equity are of the same nature with those at law. Demurrer may be also to an indictment in criminal cases.

Demy. [PAPER.]

Denarius (Lat.). A Roman silver coin worth ten asses originally, and afterwards considered equal to eighteen asses, when the weight of the latter coin was reduced to one ounce. Originally the denarius was $\frac{1}{16}$ of a pound of silver, but its weight varied. Its value is considered equal to 8d. of English money. There was also a gold denarius equal in value to twenty-five silver denarii.

Dendropereton (Gr. *δένδρον*, *tree*, and *ἐπερὶόν*, *a reptile*). This genus of Ganocephalous reptiles was discovered by Sir Charles Lyell and Mr. Dawson in the coal strata of Nova Scotia, in the hollow of the trunk of one of the gigantic *Sigillaria*. It bears close affinity to the genera *HYLONOMUS* and *ARCHGOSAUROS*.

Dendritic (Gr. *δένδρον*). A mineral is said to have dendritical markings when it contains internally, or is superficially covered with, filamentary forms, like those of moss, ferns, trees, &c. The Moss Agate, and the variety called Mocha Stone, afford familiar examples.

Dendrodoa (Gr. *δένδρον*, and *ὄν*, *an egg*). The name of a subgenus of Ascidiæ, or fixed tunicated Molluscs, suggested by the ramified form of the ovary; but this structure is not peculiar to the species included in the genus so designated.

Dendroid (Gr. *δένδροειδής*). Tree-like; that is to say, divided into branches like the head of a tree. This term is only applied in the case of small plants.

Dendromys (Gr. *δένδρον*, and *μῦς*, *a mouse*). A South African genus of Rodentia, nearly allied to the true mice, but differing in the habits of the species, which frequent the branches of trees, in which they construct their nest and bring forth their young.

Dendrophis (Gr. *δένδρον*, and *ὄφις*, *a serpent*). A genus of harmless serpents of the great family of Colubers, remarkable for their long and slender body.

Denizen (derivation uncertain, but it may perhaps be formed from 'deins né', *born within*, the old French form being *drinzein*). In Law, an alien born, who has received ex *donatione regis* letters patent to make him an English subject. He may take lands by purchase and devise; but cannot enjoy offices and trusts, &c., or receive a grant of lands from the crown.

Denominator (Lat. *denomino*, *I name*). A term used in Arithmetic, in speaking of frac-

DÉNOUEMENT

tions, to denote the number of parts into which the unit or whole is divided. Thus, for example, in the fraction $\frac{7}{12}$ (seven twelfths) of a foot, 12 is the denominator, and indicates that the unit or one foot is divided into 12 equal parts; and 7, the numerator, shows how many of these parts are to be taken.

Dénouement (Fr.) A term signifying the development of the plot or story in a novel or play, and in short in every department of literature.

Density (Lat. *densitas*, from *densus*, *thick*). This term is used in Physics to denote the quantity of matter which a body contains under a given or determinate surface; for example, a cubic foot. The quantity of matter in any body is called its *mass*, and is measured by the weight of the body, to which it is always proportional. Hence the density of any body is great in proportion as its weight is great and its volume small; or, the density of bodies is directly as their mass, and inversely as their volume. It follows also from the definition, that if two bodies have the same volume, their densities are directly as their masses or weights; and that if two bodies have the same mass or weight, their densities are respectively in the inverse ratio of their volumes. The term is generally used as synonymous with *specific gravity*.

Dental Formula (Lat. *dens*, a *tooth*). A notation used to signify the number and kind of teeth of a mammiferous animal, and usually forming the main element in its generic character. Thus the cat, or genus *Felis*, are characterised by incis. $\frac{6}{6}$; canin. $\frac{1}{1}$; premol.

$\frac{2}{2}$; mol. $\frac{2}{1}$; $\frac{2}{1}$ = 30; which signifies that they have six incisores in both the upper and the lower jaw; one canine tooth on each side of both jaws; two premolars, or false molares, on each side of each jaw; two true molares on each side of the upper, and one on each side of the lower jaw. The dental formula of man is:

incis. $\frac{4}{4}$; canin. $\frac{1}{1}$; premol. $\frac{2}{2}$; molares,

$\frac{3}{3}$ = 32.

Dentalium (Lat. *dens*). A genus of Molluscs inhabiting elongated univalve shells, resembling an elephant's tusk in miniature, whence the name.

Dentate (Lat. *dentatus*, *having teeth*). In Zoology, the margin of a part of an animal is so termed when it is cut into teeth whose sides are equal, or nearly so.

Dentatus (Lat.). Toothed; applied to the margins of bodies furnished with sharp teeth with concave edges.

Dentes. [TEETH.]

Dentils (Lat. *dens*). In Architecture, square blocks or projections in the bed mouldings of the cornices of the Ionic, Corinthian, and Composite orders, and occasionally also in the Doric: the term is applied to ornaments in cornices of rooms, which are founded

DENTITION

upon the same style of decoration. Their depth should be twice their width; and, according to Vitruvius, the intervals should be two-thirds of that dimension. In the Grecian orders they are not used under modillions; in the Roman orders this arrangement is by no means adhered to, and the modillions and dentals are constantly used in combination; the same remark applies to modern architecture.

Dentinal Tubes (Lat. *dens*). The sub-parallel branching tubes which radiate from the pulp-cavity of a tooth at or nearly at right angles with the periphery of the dentine: they have a diameter of $\frac{1}{100000}$ th of an inch, at their origin, in the human teeth, and consequently admit only the plasma, or colourless liquor of the blood.

Dentine (Lat. *dens*). The fundamental and most constant substance or tissue of which a tooth is composed. It consists of an organised animal basis disposed in the form of extremely minute tubes and cells, and of earthy particles, which have a twofold arrangement, being either blended with the animal matter of the interspaces and parietes of the tubes and cells, or contained in a minutely granular state in their cavities.

Dentirostres (Lat. *dens*, and *rostrum*, a *beak*). The name of a tribe of Insectorial birds, characterised by having a notch and tooth-like process on each side of the margin of the upper mandible. In connection with this organisation the Dentirostral birds manifest rapacious habits, and prey on smaller and weaker birds. The butcher-birds belong to this tribe.

Dentition (Lat. *dentitio*). The cutting of the teeth. At birth the teeth consist of pulpy rudiments buried in the gum; and it is not till the third or fourth month that they begin to assume shape and hardness. At this period children generally become fretful; the saliva flows copiously, and they are fond of biting upon anything hard and cold: the gums become turgid: there is more or less fever, frequently a cough; and a rash appears, commonly called the *red gum*. The symptoms generally subside in the course of a fortnight or three weeks, and the child remains tolerably free from uneasiness till the seventh or eighth month, when the gums become tender; and often so much so, at some particular spot, that the slightest touch or pressure produces extreme pain: the gums become more red and swollen, but paler at the upper part, which, just before the tooth appears, becomes blistered. During these periods an increased flow of saliva and a lax state of bowels are favourable symptoms; but where the local irritation is considerable, the gums should be lanced, and any excessive diarrhoea should be cautiously checked: small doses of magnesia, or of chalk mixture with dill water, and occasionally with a little powdered rhubarb, will generally be sufficient for this purpose. When involuntary motions of the jaws and face, or more general convulsions ensue, and are not relieved by the

loss of blood which generally follows proper lancing of the gums, or where there is drowsiness and oppressed respiration, a leech or two to the temples, and a small blister to the back of the neck, or behind the ear, must be promptly resorted to; and any sluggishness of bowels prevented, or even anticipated, by a little calomel and rhubarb, or some other active purge. Very mild opiates, cautiously administered, may afterwards prove necessary; but the administration of these in any form to young children requires the utmost caution, and syrup of poppies and other soothing remedies should never be intrusted to the nurse. The period of teething in children cannot be too scrupulously watched over, as the irritation which then ensues seems not unfrequently to lay the foundation of water in the head, especially where there is a predisposition to that disease.

Denudation (Lat. *denudo*, *I lay bare*). The wearing away of part of a deposit already completed by the mechanical action of water, either running over it quietly and constantly removing small particles, or eating away rapidly large portions by occasional heavy floods. The action of moving water is one of the principal natural causes of the modification of rocks already formed, as well as of the deposit foreign material.

Denudation is effected by the action of marine currents as well as by floods occasionally passing across a district. Perhaps the most extensive and important river denudations recorded in modern times are in volcanic districts, where the level is frequently changing and where the water acts on soft material recently ejected, such as volcanic ash. [VALLEY OF DENUDATION.]

The extent of the denudation that takes place by occasional torrents is not easily ascertained, and that which is due to the action of marine currents cannot even be guessed at. Very large results are certainly obtained every year, especially in those climates where the rain is periodical and very heavy, and the rocks consist of accumulations of no great hardness.

Denudatus (Lat.). In Botany, applied to the surface of bodies, denotes a change from downy or hairy to naked.

Denunciation (Lat. *denunciatio*). In Scottish Law, a proceeding either on civil debts or crimes, whereby the debtor or criminal is (according to an ancient fiction of law) pronounced with certain solemnities a *rebel*, analogous to outlawry.

Deobstruents (Lat. *de*, and *obstruo*, *I stop up*). Medicines which remove obstructions. The term is often used in reference to the removal of glandular complaints.

Deodand (Low Lat. *Deo dandum, to be given to God*). At Common Law, every personal chattel which had been the immediate occasion of the death of a human being is forfeited to the king on the finding of a coroner's inquest; to be applied as alms by his almoner. Where a thing not in motion was the cause of death, it was

held that the part only which was the immediate cause was forfeited; as the wheel of a cart, where a man met his death by climbing on the wheel at rest and falling from it: if in motion, the whole; as the whole cart, where the wheel went over him. However, juries for a long time past have taken on themselves to assess a sum of money, as the value of the thing forfeited; and in this way to a certain extent usurped a power which the principle of the law by no means intrusted to them; viz. of imposing a fine where they believed negligence to have caused death. But this evil was remedied by the 9 and 10 Vict. c. 62, which abolished all forfeiture of chattels in respect of homicide from Sept. 1, 1846, and all enquiry by any coroner's inquest relative to *deodands*.

Deodorisers. A term applied to a class of disinfectants especially characterised by their power of destroying fetid effluvia: chlorine and several of its compounds come under this class: chloride of zinc and nitrate of lead, which are active in decomposing sulphuretted hydrogen, are also *deodorisers*. Some kinds of charcoal, and especially that obtained from peat, when mixed with manure or excrement, not only destroys the odour, but forms an excellent compost for agricultural purposes.

Deontology (a word coined from Gr. *deon*, *due*, and *logos*, *discourse*). The science of duty; a term assigned by Jeremy Bentham to his doctrine of ethics, which is founded on the tendency of actions to promote happiness. (Bentham's *Deontology*, *init.*; also Whewell's Preface to Sir James Macintosh's *Dissertation on Ethics*, Edinb. 1836.) [ETHICS.]

Deoxydisement or Deoxydation. The chemical process of the abstraction of oxygen: these terms are synonymous with *reduction*. A compound of a metal with oxygen may, for instance, in many cases be reduced or deoxydised by heating it with carbon, or in a stream of hydrogen gas, in which case it is subjected to the process of *deoxydation*, and the metal set free.

Department (Fr. *département*). In Geography, a territorial division of the kingdom of France. Before the first revolution, France was divided into thirty-seven generalities, or governments, each of which was subdivided according to local custom into districts, bearing various names; and the laws regulating property in each were subject to extremely complicated varieties. The plan of a new division into more convenient portions was first conceived by the Constituent Assembly in 1787, and carried into effect in 1790. Mirabeau proposed the formation of 120 departments; but the actual number formed was eighty, afterwards increased by subdivision to eighty-three. M. Belleyne, geographical engineer, was the chief agent in the work. In tracing the limits of the departments, the subsisting divisions of provinces and generalities were maintained to a certain extent; but the chief object was to render them nearly equal on an average repartition of size and population, so that the more

DEPARTURE

populous departments are in general smaller; but the division is by no means uniform. The names of the departments are chiefly taken from rivers, mountains, or other well-known geographical objects. In 1808, the number was increased by conquest to 127, including twelve for the colonies. These last were subsequently retrenched; but in 1811, when the empire extended from Rome to Hamburg, the total number was 130. At present France has 89 departments, including Savoy and Nice. Each is administered by an officer named by the government with the title of *prefect*, and subdivided into *arrondissements* and *cantons*.

Departure. In Navigation, this term is used to denote the distance made good by a ship due east or due west of the meridian from which she departed. It may be defined to be the sum of all the arcs of parallels of latitude drawn between the place left and the place arrived at, through points indefinitely near to one another, taken on the distance or rhumb line, and intercepted between the meridians

passing through those points. Thus, let P represent the pole of the earth, UZ an arc of the equator, A and F two places on the earth, PU, PZ their meridians. Through the points A and F suppose a curve line AF to be drawn cutting all the intermediate meridians, PV, PW, PX, &c. at the same angle; that is, making the angle PAB = PBC = PCD = &c. Then this common angle PAF is called the *Course* [which see]. The arc AF, called the *distance*, is supposed to

be divided into an indefinite number of parts by the meridians PV, PW, PX, &c., and through the points A, B, C, &c., the arcs of parallels of latitude AM, BN, CO, &c. are drawn. On this supposition (namely, that the points A, B, C, &c. are indefinitely near to each other) the elementary triangles ABM, BCN, CDO, &c. may be considered, without any error, as *right-angled plane triangles*, and the departure from A to F = AM + BN + CO + . . . + ER. The departure is connected with the distance and course by the formula, $\text{departure} = \text{distance} \times \sin \text{course}$.

The term *departure* is also used in Geometry to indicate the distance from the foot A of the perpendicular let fall from a given point C upon a given line AB, to the foot B of any oblique let fall from the same point C upon the same line.

Dependent and Independent Variables. A variable quantity whose value is dependent upon that of another quantity, or upon the values of several other quantities, is said to be a function of the latter, or a *dependent variable*. Thus, if

$$y = ax^2 + bx + c,$$

y is said to be the *dependent* and x the *independent* variable.

DÉPÔT

pendent variable, it being understood that the variations in the value of x are arbitrary, and regulate those of y.

Dephlognation (from Lat. de, and Gr. φλόγμα). The operation of freeing spirit of wine and certain other fluids from the water which they usually contain. A very strong and pure spirit is often said to be highly *dephlognated*.

Dephlogistication. A term applied by the older chemists to certain processes by which they imagine that phlogiston was separated from bodies. They regarded oxygen as common air deprived of phlogiston, and hence called it *dephlogisticated air*. [PHLOGISTON.]

Depilatory (Lat. de, from, and pilus, hair). Any application which removes hair from any part of the body. The celebrated Turkish Depilatory is a mixture of 7 parts of quicklime and 1 of orpiment. The latter ingredient is probably useless; for when powdered quicklime is made into a thin paste with water, and applied by a camel-hair pencil to any part till it produces a tingling or burning sensation, on wiping it off with a wet sponge the hair, especially if it be soft and delicate, is removed with it.

Deploy (Fr. deployer, to unroll). In the art Military, to open or extend troops from column into line.

Depolarisation of Heat. [HEAT.]

Depolarisation of Light. [LIGHT.]

Deportation (Lat. deportatio). In French law, a punishment equivalent to transportation in English. It is ranked as third in degree; after capital punishment, and condemnation to the galleys or public labour (travaux forcés) for life. Deportation for political offences was a common punishment at one period during the French revolution; especially after the fall of Robespierre and his party. It was then usually executed by conveying the criminals to Cayenne in South America. It has been revived both to that region and to Algeria, under the law of 1836, art. 17.

Deposition (Lat. depositio). In Law, the testimony of a witness, put down in writing, in answer to interrogatories legally exhibited for that purpose. In the court of chancery such depositions form an established medium of proof; and the interrogatories are exhibited, in London before examiners, in the country by commissioners appointed for that purpose. Depositions in civil actions, in the courts of common law, are regulated by the st. 1 Wm. IV. c. 22. By 7 Geo. IV. c. 64, the examination of the prisoner and witnesses before a magistrate on a charge of felony must be taken down in writing, and returned to the court. If duly taken, these depositions are evidence at the trial under certain restrictions, and are made so in the absence of the prisoner, in case of death or illness, by 11 & 12 Vict. c. 42.

Dépôt (Fr.). A place where all sorts of military stores and provisions are kept, or where recruits are received and trained. This

DEPRESSED

term is also applied to that portion of a battalion which remains at home when the rest is ordered upon foreign service. The *dépôts* of several battalions are combined, and form a *dépôt* battalion.

Depressed (Lat. *depressus*, part. of *deprimo*, *I depress*). In Zoology, the whole or part of an animal body is so called when its vertical section is shorter than the transverse.

Depression of Equations. In Algebra, the derivation, from a given equation, of another lower in degree, whose roots are related in a known way to those of the first. This reduction can always be effected, of course, by simple division when one or more of the roots are known; but without knowing the roots beforehand the equation may be depressed: 1st. When some particular relation subsists between two (or more) of the roots; for example, if an equation contain equal roots, these may be found, and the equation reduced by as many dimensions as there are equal roots; 2nd. If two roots of an equation be equal in magnitude, but opposite in sign; and 3rd. If the equation be a reciprocal one, that is to say, such that its form is not changed, by changing x into $\frac{1}{x}$ [EQUATIONS, THEORY OF.]

Depression of the Horizon. [DIP OF THE HORIZON.]

Depressor Muscles. In Anatomy, those muscles which lower the bone to which they are attached, in contradistinction to *ELEVATOR MUSCLES* [which see].

Deputies, Chamber of (Fr. *chambre des députés*). The lower of the two legislative chambers in France under the monarchy, from 1814 to 1848. The right of election was latterly in persons of twenty-five years of age paying 200 francs of direct contributions. There were 459 members of the chamber, each elected by a separate electoral college: the election was by ballot. To be eligible to the chamber, the candidate must be thirty years of age, and pay 500 francs of direct taxes. The total number of electors in 1846-7 amounted to 200,000. The duration of the chamber was triennial.

The Chamber of Deputies was divided into nine *bureaux*: which were renewed every month. To these *bureaux* questions were referred by the chamber; as well laws proposed by the king or the house of peers as propositions of individual members. The *bureaux* reported on the question, after separate discussion in each, before the general discussion in the chamber began. Except in case of dissolution, measures commenced in one section passed on to the next in the same stage in which they had been left. The vote on a proposed law was secret, on any other proposition open.

The *côté droit*, *côté gauche*, and the *centres*, formed the three grand divisions of which the Chamber of Deputies was composed. When the three great chambers of the States-General of 1789 were consolidated into one by the designation of the National Assembly, the most distinguished members of the aristocratic

DERIVED FUNCTION

and republican parties were in the habit of sitting together, for the purpose of communicating more easily with one another: the former occupied the benches to the right, the latter those to the left of the president's chair; while the centre benches, or those fronting the president's chair, were filled by those who held various intermediate shades and modifications of opinion. This custom remained in force down to the fall of the monarchy, and nothing could exceed the nicety with which each variety of political opinion was grouped in the French representative assembly. The *côté droit*, or the side to the right of the president's chair, was occupied by those members who inclined to favour the royal prerogative; the *côté gauche*, on the other hand, was set apart for those who were more in favour of popular ascendancy; while those members who, with considerable difference of opinion among themselves, generally supported the ministers, occupied the *centres* (*centre droit* et *centre gauche*), which might thus be termed the *immaterial benches*. But it has been judiciously remarked that, 'as in every great political party there are shades of opinion, some being more warm and violent, and others more moderate, discriminating, or cautious, so both the *côté droit* and the *côté gauche* were generally subdivided into three sections each. The more zealous royalists took their seats at the outer extremity of their side of the house towards the president, and were styled the *extrême droit*: the ultra-liberals sat on the corresponding seats on the opposite or left side, and were styled the *extrême gauche*.'

Derbyshire Spar or **Fluor Spar.** It is of various colours; and the large nodules, which are peculiar to Derbyshire, are often beautifully veined, and admit of being turned in the lathe into vases and small columns. A fine variety of this spar occurs in Cumberland, in cubic crystals of a pale sea-green colour. The cube is the most common form of the crystals of fluor; but it also occurs in octohedra, some fine specimens of which have been found associated with galena in the mine of Beer Alston upon the Tamar. It consists of fluorine and calcium.

Derelict. In Law, lands left dry by the recession of the sea are so called. Also vessels forsaken at sea.

Derivation (Lat. *derivatio*). In Etymology. [GRAMMAR; LANGUAGE.]

DERIVATION. The peculiar constant deviation of an elongated projectile fired from a rifled gun. [PROJECTILE; GUNNERY.]

Derivations, Arbogast's. [ARBOGAST'S METHOD OF DERIVATIONS.]

Derived Function or **Derivative.** A term first used by Lagrange in his *Calcul des Fonctions* to indicate the coefficient of h in the developement of a function $F(x+h)$ according to powers of h . It is itself a function of x , and is usually represented by the symbol $F'(x)$. In a similar manner the derived function of $F'(x)$ is termed the *second derived function* of $F(x)$

DERM

and denoted by the symbol $F''(x)$. By allowing h to diminish indefinitely, the identity of the derived function and the differential coefficient $\frac{d}{dx} F(x)$ is at once seen. [DIFFERENTIAL COEFFICIENT.]

Derm (Gr. *δέρμα*, *skin*). The true or organised layer of the tegumentary covering of animals. It is composed of a close and irregular network of whitish fibres, consisting of condensed cellular tissue, whence it is also termed *corium*, and is everywhere traversed by capillary arteries and veins, absorbents and nerves; and, in the mammalia, by the roots of the hairs and the ducts of the sudorific follicles; it is covered with the *rete mucosum* and *epiderm*. The derm is of considerable thickness in the rhinoceros, hippopotamus, elephant, &c.; whence the name *Pachyderma* applied to the order containing these and allied quadrupeds.

Dermapterans, Dermaptera (Gr. *δέρμα*, and *πτερόν*, *a wing*; *skin-winged*). An order of insects dismembered from the *Orthoptera* of Latreille, and including those which have the elytra wholly coriaceous, and always horizontal; the two membranous wings are folded longitudinally, and the tail is armed with a forceps. This order is represented by a single Linnæan genus, viz. *Forficula*, or earwig; insects which are common in damp places, and often found in numbers under stones, and beneath the bark of trees: they do much damage in gardens by preying upon the fruit. The English common name, and also the French, *pierce-oreille*, relate to a habit absurdly attributed to these insects of penetrating the ears.

Dermatobranchus (Gr. *δέρμα*, and *βράχια*, *gills*). A genus of Gastropods, or snails, in which the branchiæ consist, as in *Scyllæa*, of ramified productions of skin.

Dermatology (Gr. *δέρμα*, and *λόγος*, *a discourse*). A treatise or history of the skin and its diseases.

Dermestes (Gr. *δερμότης*, *skin-eater*). The name of a Linnæan genus of Clavicorn Coleopterous insects, noted for their ravages on dead animal substances, especially the preserved skins of animals, and which are consequently the pests of a museum. The old genus *Dermestes* is subdivided in modern entomology into several subgenera. The *bacon-beetle* (*Dermestes lardarius*) is the type of that to which the term *Dermestes* is now confined.

Dermobranchiata, Dermobranchiata (Gr. *δέρμα*, and *βράχια*; *gills on the skin*). The name of a family of Gastropods, comprehending those which respire by means of external branchiæ or gills, having the form of membranous plates, filaments, or tufts.

Dermohæmal (Gr. *δέρμα*, and *αἷμα*, *blood*). The ossified developments of the dermo-skeleton in fishes are so called when they form points of attachment for the fins on the ventral or hæmal side of the body. [DERMONEURAL.]

DERVISE

Dermoneural (Gr. *δέρμα*, and *νεῦρον*, *nerve*). When the ossifications of the dermo-skeleton extend on the neural side of the body, the term *dermoneural* is applied to them. They form the rays of the dorsal, and the upper rays of the caudal fins. Both the *dermoneural* and *dermo hæmal* spines are supported on the *internural* and *inter hæmal* spines respectively, which are embedded in the flesh between the *neural* and *hæmal* spines of the endoskeleton.

Dermopteri (Gr. *δέρμα*, and *πτερόν*, *a wing*). An order of fishes in which the endoskeleton is unossified; the exoskeleton and vertical fins mucodermoid; no air-bladder. It comprehends the Lancelet (*Amphioxus*) amongst other forms.

Dermoskeleton (Gr. *δέρμα*, and *σκελετόν*; *skin-skeleton*). A term applied to the coriaceous, crustaceous, testaceous, or osseous integument, such as covers most invertebrate and some vertebrate animals; it serves more or less completely the office of protecting the soft parts of the body, and as a fixed point of attachment to the moving powers.

Derrick. In Military language, a beam of wood, one end resting on the ground, the other supported at any convenient angle by guys. It gives a point or fulcrum in space to which tackle can be applied for moving heavy ordnance, &c.

DERRICK. In Nautical language, used in a variety of meanings, but chiefly for a tackle used for the purpose of hoisting provisions, stores, guns, &c. in and out of a ship.

The name *derrick* has also been applied to a floating crane, which consists of a large iron pontoon of great width, divided into a number of watertight compartments. From the centre rises a powerful tripod mast, across which turns a yard of great strength. To one arm of the yard are suspended several fourfold blocks, through which pass the chains intended to hoist the weight. From the blocks these chains pass over the top of the mast to the opposite extremity of the yard, and thence to drums worked by powerful steam-engines in the pontoon. When the weight is suspended on one side, the water is admitted as a counterpoise into some of the compartments on the other. The vessel has powers of slow locomotion, and is employed in the lifting of vessels to have their bottoms examined, the placing of machinery, recovery of wrecks, &c. Derricks are extensively used in America. In England the Thames Iron Company constructed one in 1859 which was 270 feet long, 90 feet wide, with a mast 80 feet to the yard and 50 above, the yard being 120 feet long. Two engines enable this machine to lift and carry loads of 1,000 tons.

Dervise (from a Persian word signifying *poor*). The name of certain classes of religious persons among the Mohammedans of Turkey and Asia. They live partly in monasteries, partly alone, either stationary or wandering; and belong to a great variety of orders, of

which there are thirty-two (it is said) within the Turkish empire only. As in most other countries, there has existed in Persia from time immemorial a class of enthusiasts, who, impressed with the conviction that poverty is the only passport to virtue, have voluntarily renounced all the comforts and charities of this life, and devoted themselves to religious exercises. In most instances, however, such enthusiasts have been more famed for the theory than the practice of sanctity; and the dervises do not appear to form an exception to the rule.

Descant (Ital. *descanto*). In Music, composition in several parts. It is either *plain*, which consists in the orderly placing of many concords answering to simple counterpoint; *figurate* or *florid*, wherein discords are employed; or *double*, where the parts are so contrived that the treble or any high part may be made the bass, and the contrary.

Descartes' Rule of Signs. A theorem by means of which the maximum number of positive or negative roots of an algebraic equation can be immediately ascertained by inspection. The theorem reduces itself essentially to this: *the number of positive roots of an equation cannot exceed the number of variations in the signs of its coefficients, considered in their proper order.* The demonstration is simple, and is given in all text-books on the theory of equations. As an illustration, take the cubic equation

$$F(x) = 3x^3 - 7x^2 + 11x + 4 = 0.$$

Inasmuch as there are but two variations of signs on passing from one extreme term to the other, through the intermediate ones, we conclude that the cubic cannot have more than two positive roots. To ascertain the maximum number of negative roots, it is merely necessary to apply the same theorem to the equation which is obtained from the original by changing x into $-x$. Thus the positive roots of

$$F(-x) = -3x^3 - 7x^2 - 11x + 4 = 0$$

are negative roots of the original cubic, and by Descartes' rule their number cannot exceed one. Descartes' Rule is a particular case of FOURIER'S THEOREM.

Descent. In English Law, if a person die seised in fee-simple, otherwise than as a joint tenant of lands or tenements which he has not disposed of by will, they will descend to his heir. Such seisin is either actual possession, or virtual; as possession by the tenant of a chattel interest, whose possession is always held to be the same with that of the remainderman, or reversioner, who is to succeed him. If a person have become possessed by purchase of lands or tenements in fee-simple, of which, from the nature of the estate, he cannot obtain seisin (as a remainder expectant on a particular estate of freehold), these likewise descend to the heir in case of his intestacy. It is well known that by the common law of England the rules of descent were different from those obtaining in

other countries; that a direct lineal ancestor could in no case inherit from his descendant; that brothers and sisters of the half-blood, i. e. sprung from another mother or from another father, were also excluded from the succession. These rules have now (by 3 & 4 Wm. IV. c. 106) been wholly removed or modified; so that the law of descent recognises in succession the following heirs: 1. The eldest or only son, or his issue. 2. The younger son, or his issue. 3. The daughter, or, if more than one, all the daughters as coparceners and their issue; such issue claiming *per stirpes*, not *per capita*, i. e. claiming only the share of their respective mothers. 4. In default of lineal descendants, the nearest lineal ancestor now succeeds, in preference to any person who would have been entitled to inherit either by tracing his descent through such lineal ancestor, or in consequence of there being no descendant of such lineal ancestor; e. g. a father inherits before a brother, a grandfather before an uncle, &c. 5. In default of father, brothers, or sisters of the whole blood and their issue, then the inheritance devolves on the eldest brother or sister of the half-blood by a different mother, the half-blood following the same rule where the inheritance devolves on the descendant of any other ancestor. 6. On failure of male ancestors on the paternal side and their descendants, female paternal ancestors and their descendants. 7. On failure of these, the mother, her ancestors—first male, then female—and their respective descendants. 8. The half-blood follow always next after any relation in the same degree of the whole blood and his issue, if the common ancestor be a male; next after the common ancestor, if a female: so that the brother by the half-blood on the part of the mother inherits next after the mother. Descent is always traced from the first purchaser, that is, the first who acquired the land otherwise than by descent; but the last owner is presumed to be the first purchaser unless the contrary can be proved. In some particular localities the custom of gavelkind prevails, by which all the sons inherit equally from the father. By the custom of borough English, the youngest son is heir. Bastards and aliens cannot inherit; but a natural-born subject may derive his title (under certain restrictions) through alien ancestors.

DESCENT. In Mechanics, the motion of a body towards the centre of the earth, caused by the attraction of gravity. [ACCELERATION.]

Descriptive Geology. By *descriptive geology* is meant a continuous and definite account of the materials that form the external crust of the earth, including *first* the nature of the rocks or inorganic materials themselves, the mechanical changes that have affected them, and the nature of their organic contents or fossils; *secondly*, the order of arrangement of the materials; and *thirdly*, a distinct and orderly history of the separate formations.

1. *Inorganic Materials of the Earth's Crust.*—

DESCRIPTIVE GEOLOGY

The materials of the earth are certain combinations, for the most part very abundant, of known and common minerals, either such as are presumed in the present state of our knowledge to be elements, or certain definite compounds not easily reduced to their elements. These are called **Rocks**, and are of three kinds: they are either clearly derived from water, as loose sands, marls, clays, &c., and are then called **Aqueous Rocks**; or they are distinctly formed by the action of intense heat, by which they have been melted, and are called **Igneous Rocks**; or lastly (and this is far more commonly the case), they have marks of having been originally aqueous, but have since become much changed; these are **Metamorphic Rocks**. Some of the latter are called **Crystalline Rocks**. These may have been originally aqueous, but have now quite lost all traces of original structure. Each of these kinds of rocks will be found described under its own heading, and to these separate accounts the reader is referred for more detailed descriptions.

Rocks, being the raw materials of the earth, must be studied with reference to their history. To enable the student to familiarise himself with the various facts known concerning them, he must understand the varieties of *structure* [**STRUCTURE OF ROCKS**] and also the *mechanical position* of the rocks.

All rocks are composed of minerals; but the variety of elementary substances that enter into the great mass of the earth is singularly small. The variety of simple minerals is not large considering the almost infinite combinations of which the number of elements is capable, and in fact the great mass of the matter composing all rocks comes properly under one of the general terms **Limestone**, **Sandstone**, and **Clay**. In addition to the rocks which belong to the aqueous group are **Granite**, **Lava**, **Basalt**, and **Porphyry** of various kinds [**Igneous Rocks**, **Crystalline Rocks**], and also **Gneiss**, **Mica Slate**, **Clay Slate**, and others. [**Metamorphic Rocks**.] Notices of all these will be found in separate articles.

The great modifying force that converts rocks from the simplest mechanical condition through all stages of difference, both apparent and real, is that spoken of by geologists under the term *metamorphism*. By its agency the muds become converted into schists, shales, and slates; the calcareous mud into limestone, or the heaps of accumulated sand into sandstone. Owing to the action of this force, again, further important changes take place in structure and even in the arrangement of the atoms of which the rock is made up; they become *crystalline*, and in so doing occupy smaller space; they contract, and fissures occur in them [**Mineral Veins**]; the cavities and fissures become filled with new combinations of mineral substances and metals, and all appearance of original aqueous origin is lost.

But other causes, more mechanical, have

meanwhile produced change. Materials originally accumulated at the bottom of water at moderate depth, are sunk lower and lower, and new materials are heaped upon them. Other parts of the earth's crust are subjected to some upheaving force, and are lifted up either on a line [**Axis of Elevation**] or at a point. The overlying masses are thus tilted, and are seen to be inclined to the horizon. [**Dip and Strike**.] Sometimes the rocks dip away from a central line [**Anticlinal Axis**] or dip towards such line [**Synclinal Axis**]. Occasionally they are broken, so that the continuity of a bed is interfered with. [**Fault**.]

It is not always the case that the various beds [**Strata**] of mineral matter or rock are parallel to one another. [**Conformable Stratification**.] Sometimes the lower beds are much inclined, and the upper less inclined or level. [**Unconformable**.] Occasionally portions of a bed have been carried away or scooped out as by water [**Denudation**], and then horizontal beds being deposited appear unconformable, though really conformable. It will happen by some extraordinary confusion of nature that rocks are thrown completely over, so as to have the opposite direction from that they ought to have. [**Reversed Dip**.] Such phenomena are doubtful or obscure stratification are sometimes met with, and false stratification will occasionally puzzle the young geologist.

Rocks, having generally been formed under water, naturally contain various fragments of vegetable and animal matter. These are **Organic Remains**, and possess a double value as referring to natural history generally, and also to geology. As they belong to ancient races, many of which are now extinct, their study forms a separate science. [**Paleontology**.] These specimens, being the most remarkable of things *dug up*, are called **Fossils**.

2. *Order of Arrangement of the Materials.*—The classification of rocks [**Classification**] may be based either on a consideration of the circumstances under which they were found, or of the materials of which they are constructed, or of the successive history they teach. The most convenient method in practice is to regard chiefly their fossil contents when they possess evidence of this kind; and thus paleontology has become subsidiary to geology and essential to the geologist.

In arranging rocks by their contents, it has been found convenient to take advantage of certain apparent lines of separation that occur in the countries where geology was first studied, and make these the standard of comparison for the whole world. Of the permanent retention of these standards when the science is more thoroughly advanced, we need not here discuss the probability. Of their present convenience there is no doubt.

Assuming organic remains as the basis of geological classification, all rocks would seem divisible into two classes—**fossiliferous** and **unfossiliferous**. This is not, however, so completely the case as might be supposed; for it

DESCRIPTIVE GEOLOGY

not unfrequently happens that rocks deposited mechanically, and not greatly metamorphosed, are yet quite without fossils. Thus relative position in a recognised series comes to be considered as of great value in determining the true position of a rock, or series of rocks, when examined in a new country. Under the head of fossiliferous rocks are thus included many large masses of rocks, in which fossils are rarely or never found.

To understand the further subdivisions of these rocks we must consider the circumstances under which deposits of any magnitude are now being made. There is now, and, so far as we know, there must always have been, a very large area of the earth's surface on which not only no deposits are being made, but which are actually providing the material of the deposits that are going on. The places where accumulation of material takes place are comparatively few and small. They include only certain coast lines and certain expanses of fresh and salt water, some deep recesses of the ocean, and a few lakes. They certainly do not include any portion of the land, and they probably do not include the open part of the large oceans. That the land and deep ocean floors may receive large deposits, the one must be depressed and the other elevated; and these processes of elevation and depression we are bound to suppose are gradual, slow, and to a certain extent reciprocal. There is thus only a very imperfect sequence, and in any one spot the gaps or intervals are likely to be much more abundant than the continuous series.

Owing to causes which we cannot here discuss, the sequence in Western Europe and the British islands admits of being conveniently grouped into three divisions; in other words, there are two principal intervals, and no more, in the long series of stratified fossiliferous rocks. In many parts of the world the gaps are much more numerous, and nowhere, as hitherto known, is the sequence more complete.

Estimating the intervals as marking lapse of time, and regarding the series of rocks as on the whole representative, these three periods are called respectively (1) PALÆOZOIC, (2) SECONDARY or MESOZOIC, and (3) TERTIARY or CAINOZOIC. Using this Greek nomenclature, all the names refer to the relative antiquity of the remains of life found in them. We may regard them as meaning the *older*, *intermediate* or *middle*, and *modern* groups.

The following tabular statement will give a general view of the details of arrangement under their general heads, so far as investigation has yet gone. That on the whole the series is correct may be regarded as certain, but it can in no sense be looked on as complete. It represents a large amount of truth, but much still remains to be made out by careful investigation, and a comparison of observations in every part of the globe. Care has been taken to exclude, as far as possible, theoretical views and names that involve any disputed views in geology.

TABULAR VIEW OF THE SUCCESSION OF FOSSILIFEROUS ROCKS.

RECENT DEPOSITS.

Fresh-water and Land.

- Mud, silt, and stones, in river beds and deltas, and in lakes. [ALLUVIUM.]
- Peat bog, angular and rolled gravel, and sand from glaciers. [DRIFT.]
- TRAVERTIN, from water holding bicarbonate of lime in solution.
- TUFA, and other volcanic ash.
- SILICA, from hot water in volcanic districts.
- BRECCIA, in caverns.
- Rollad material derived from occasional torrents. [DILUVIUM.]

Marine—

- Coral reefs.
- Angular and rolled material [DRIFT] derived from the destruction of shores.
- Angular and rolled gravel from icebergs. [DRIFT.]

TERTIARY OR CAINOZOIC DEPOSITS.

NEWEST TERTIARY or UPPER QUATERNARY (*Post Pliocene*).

Fresh Water—

- Older accumulations at the mouths of large rivers. *Löss* of the Rhine.
- Older diluvium. Peat with human remains.
- Bluffs of Mississippi and almost all other large rivers.
- Older rich vegetable soils, *Tchernozem*, *Regur*, &c.
- Cavern breccias with bones, in many parts of the world.
- Old travertine and tufas.
- Silicified trees and various deposits of silica.

Marine—

- Raised beaches and submerged forests.
- Newer boulder formation and gravel.
- Recently elevated coral reefs.
- Recently elevated volcanic islands.

PLISTOCENE (*Middle Quaternary*) and NEWER PLIOCENE.

- Glacial drift or boulder formation of Northern Europe, Asia, and North America, with numerous remains of gigantic mammals of extinct species.
- Cavern deposits and breccias in Europe, Asia, America, Australia, &c.
- Crag of Norwich.
- Pampas deposits of South America.
- Limestones of Girgenti in Sicily.

OLDER PLIOCENE.

- Subapennine beds.
- Crag, red and coralline, and crags of Normandy and Antwerp.
- Newer Sewalik beds of India.

MIocene of MIDDLE TERTIARY.

- Faluns of the L. e.
- Vienna basin and basin of the Danube.
- Older Sewalik beds of India.

Eocene of OLDER TERTIARY.

- Hempstead and Bembridge series (Isle of Wight).

Upper

- Grès de Fontainebleau and Auvergne lacustrine beds.

- Limburg beds of Belgium.
- Mayence basin and part of German brown coal.
- Barton clay and Bracklesham sands (England).
- Calcaire grossier and grès de Beauchamp (France).

Middle

- Brussels and Laocœn beds (Belgium).
- Clatsone beds, Alabama (North America).
- Nummulitic formation.

Lower

- London clay series and contemporaneous beds in France and Belgium.
- Argile plastique.

DESCRIPTIVE GEOLOGY

SECONDARY OR MESOZOIC DEPOSITS.

UPPER CRETACEOUS.

- Upper* { Chalk generally. Fæve beds and Maestricht beds.
Upper quadermandstein.
- Lower* { Upper greensand and gault
Hippurite limestone.
Plänerkalk and lower quadermandstein.

LOWER CRETACEOUS.

- Upper* { Lower plänerkalk.
Lower greensand series.
Neocomian series (Upper).
- Lower* { Wealden series.
Lower Neocomian.

UPPER OOLITE.

- { Purbeck. Portland and Kimmeridge series.
Serpulite limestone of Germany.
Lithographic limestone of Bavaria.

MIDDLE OOLITE.

- { Calc grit, coral rag, Oxford clay and Kelloway rock.
Nelsonian limestone.

LOWER OOLITE.

- { Great oolite series.
Green limestone.
Inferior oolite series.
Iron beds of Normandy and France.

LIASINE SERIES.

TRIASSIC SERIES.

- { New red sandstone, and bunter sandstein with salt.
Keuper, muschelkalk and bunter sandstein.

PALÆOZOIC DEPOSITS.

PERMIAN SERIES.

- { Magnesian limestone, lower new red sandstone, and dolomitic conglomerate.
Roth liegender, kupfer schiefer, and Vosges sandstone.

CARBONIFEROUS SYSTEM.

Upper Series—

- { Coal measures with shales and grits and much coal.
Millstone grit overlying coarse and fine shales.

Lower Series—

- { Carboniferous limestone and kiesel-schiefer. Deposits and veins of lead and zinc ore.
Lower limestone and shales with poor coal.
Ooliferous series and calp. Fentramite limestone, U.S.

DEVONIAN SYSTEM.

- { Herefordshire conglomerates and Scottish sandstones of the old red sandstone.
Russian Devonian series, Catakill group, U.S.
Eifel limestone, Spirifer sandstone, and old Rhenish greywacke.
Devonshire series of shales and limestones.
Corn-stones of Herefordshire. Arbroath paving-stones and Cathness schists.

SILURIAN SYSTEM.

- { Tllestons. Ludlow and Aymestry rocks. Wenlock series and Upper Caradoc series.
New York series, upper part. Bohemian series.
Russian and Scandinavian, and North American limestones.

CAMBRIAN SYSTEM.

- { Lower Caradoc and Llandello flags. Balalimestone. Scotch graptolite schists and Kildare limestone (Ireland).
Lower part of New York and Bohemian series. Angers slates.
- { Arenig and Tremadoc beds and Lingula flags. Harlech grits, Llanberis slates, and lowest Wicklow fossiliferous rocks.
Bohemian primordial zone. Swedish alumi Potadam sandstone. Wisconsin

LAURENTIAN SYSTEM.

- { Gneiss and mica schist with crystalline limestone, occupying a large area north of the St. Lawrence in North America. Fossils have been found in serpentines of this series.

Some details of each principal group of rocks named in the above table will be found under its own heading, and the characteristic groups of fossils will also be explained so far as a knowledge of them is necessary. Employing the various references, the reader may obtain an idea of the extent of the department of geology thus outlined.

Beneath and amongst the stratified rocks are various others that are crystalline, altered, and unstratified, and to all appearance the result of causes now most nearly exemplified in the case of volcanic products. Those underlying the whole series, or whatever part of the series carries us down below fossiliferous rocks, are usually porphyritic, and of the nature of granite. Those filling up crevices, whether formed by contraction or elevation [MINERAL VEINS], are frequently crystalline and metaliferous; and igneous rocks, now lying on the surface or interposed between fossiliferous rocks, clearly mechanical in their origin, are *basaltic, trachytic, or greenstone*.

All these igneous rocks agree in the absence of any marks of mechanical origin. The three latter have been apparently thrust up through overlying strata in a melted state. The first-named have been formed at great depth in the earth, subjected to influences only existing there, and little known to us. They were probably elaborated from old rocks, but are now altogether crystalline. Lastly, the minerals filling crevices have been separated and deposited atom by atom either with water or steam, independently of mechanical agency; but not without reference to the nature of the enclosing rock.

It will be seen from this brief account how independent of the stratified rocks, in respect to age, all these crystalline rocks are.

The arrangement, then, of the igneous, chemical, or unstratified rocks must be essentially distinct, and governed by different principles from those enunciated in reference to the stratified series. When underlying, they are not necessarily older; and when they are interstratified, or occupying veins, their age is marked only in reference to the rocks they cover or penetrate. The granite of Cornwall below Silurian rocks, which are little altered by its proximity, is doubtless very old; but the granite of the Alps, similar if not identical in all important characteristics, is probably newer than some of the middle secondary rocks. Such granite may be in course of formation at this moment, being made out of tertiary rocks; but when cooled may well agree in all essentials with the oldest. So, again, mineral veins in the granite and slate of Cornwall contain the same minerals arranged in the same way as is the case with veins in similar rocks of the tertiary period occurring in the copper-mining

district of Algeria. So also basalt was poured out over the chalk on the north coast of Ireland before the commencement of the deposit of tertiary rocks; but it is exactly similar to the lava of Iceland or Etna erupted during this century.

A third group of rocks exists—those which were certainly once of mechanical origin, and were deposited after long suspension in water, but which now are so completely altered as to have lost almost all mark of their origin. Gneiss, micaceous and clay slates, quartzites, and some marbles are all of this kind: they are *metamorphic rocks* in the strict sense of the word, and have undergone a great change. They must be arranged according to some method that does not require an examination or comparison of fossils; for with them to be fossiliferous is an exceptional condition. Their mineral condition, also, though by no means always the same, is strictly dependent on causes which seem to have no reference to the date of their origin.

Ultimately, no doubt, all rocks must be judged of by a consideration of the determinable deposits containing fossils with which they are most nearly associated.

3. *Detailed Account of Formations.*—This part of the subject is given under the various principal headings referred to in the list of formations. It is unnecessary here to repeat the details.

Descriptive geology with palæontology—the two forming together one great department of geology—is thus seen to involve a serious and lengthened statement of facts and necessary inferences. When properly studied, it leads on the one hand to very important practical conclusions, and on the other to philosophical considerations and theoretical views hardly less important. The former will be noticed under the head of *Economic Geology*, and the latter will some day form a department which may with propriety be called *Physical Geology*; but at present, and in this work, theoretical considerations are best excluded. [*Geology*; *Physical Geology*; *Aqueous Rocks*.]

Descriptive Geometry. The object of Descriptive Geometry, in the sense first used by Monge, is to obtain such a representation, *in plano*, of an accurately defined body in space as will serve for the investigation of the *metrical* as well as of the descriptive properties of that body. It differs from ordinary perspective inasmuch as by the latter method the actual dimensions of a body cannot be ascertained from its representation.

In descriptive geometry, points in space are represented by their orthographical projections on two planes, at right angles to each other, called the *planes of projection*. It is usual to suppose one of the planes of projection to be horizontal, in which case the other is vertical; and the projections are called *horizontal* or *vertical*, according as they are on the one or the other of these planes. Accordingly, any curve in space will be represented by two curves

in the horizontal and vertical planes, and a curved surface by the corresponding representations of certain points and curves on that surface. Thus a plane would be completely defined by its intersections with the planes of projection. The intersections of a line or surface with the planes of projection are called its *traces*. Again, a sphere may be conveniently represented by the projections of its horizontal (or vertical) great circle; a cylindrical surface by its trace on one of the planes of projection, and the projection of any generator on the other; a cone by the projections of its vertex and by one of its traces, &c.

Although applicable to sculpture, architecture, painting, and all mechanical arts, it was chiefly in consequence of its application to civil and military engineering, and to fortification, that this branch of geometry received a distinctive appellation. It was considered of sufficient importance to form one of the principal departments of study in the Polytechnic school of France. The best systematic works written on the subject are those of Monge, Hachette, Vallée, Olivier, Amiot, Leroy, Lacroix (*Essais de Géométrie &c.* Paris 1840), Hall and M. de la Gournerie.

Desert (Lat. *deserta*, forsaken places). A term generally used to designate an uninhabited place or solitude. In this sense, it is equally applicable to the fertile plains watered by the Marañon, and the wastes of Libya; but it is applied more particularly to the vast sandy and stony plains of Africa and Asia. In every region of the globe plains are to be found of greater or less extent, which, though marked by strong features of resemblance in their grand outlines, exhibit with the different latitudes in which they are placed a corresponding variety of character, and according to the distinguishing peculiarities of each are known by different appellations. Thus we have the *STEPPES* of Europe, the *DESERTS* of Asia and Africa, the *SAVANNAHS* of the Mississippi and the Missouri, and the *PAMPAS* and *LLANOS* of South America. [See these different articles.]

The most striking feature of North Africa consists of its immense deserts, which have in all ages presented to the speculations of the geographer objects highly worthy of attention. Of these the chief is the *SAHARA*, or the *Desert*, so called by way of eminence. In many parts the dreary waste of loose and hardened sand is broken by low hills of naked sandstone, or by tracts of arid clay, and occasionally it is enlivened by verdant isles or *OASIS*, which serve as resting places for the caravans that traverse these dismal regions. But for these *oases*, indeed, the Sahara would be wholly impassable. It presents, says Malte Brun, no traces of a beaten path; and the caravans that traverse it, directing their way by the polar star, describe a tortuous road in order to profit by the *oases*, which are represented as brilliant with vegetation, but which probably owe a great part of their reputation to the contrast they form with the absolute barrenness of the desert.

The great deserts of Africa are separated from those of Asia only by the valley of the river Nile and the Red Sea. Soon after quitting the Nile, the traveller by the route of Suez encounters saïd, which is continued into the centre of Arabia, where it forms the desert of Nedjed, extending to the valley of the Euphrates. The sandy zone then inclines northward, enters Persia, and forms the saline deserts of Adjemi, Kerman, and Mekran; it is turned north-east by the valley of the Indus, passes through Cabul and Little Bukharia, till it joins the vast deserts of Cobi and Shamoo, which occupy so large a portion of Central Asia between the Altaian and Mustag chains, and reach to the confines of China. The sandy zone, thus traced throughout the breadth of the ancient continent from Western Africa to 120° of east longitude, has been computed to cover an area of 6,500,000 square miles; but the Asiatic portion of this tract includes many chains of mountains and fertile valleys. It is characterised by the occurrence of arid wastes of sand or clay, sometimes with saline incrustations on the surface, and is remarkably deficient in considerable rivers. Except the Nile, the Euphrates, the Indus, and the Oxus, there are no large rivers in a region which embraces almost a fourth part of both Africa and Asia. This portion of Central Asia forms a series of elevated plains 6,000 miles in length from east to west. Some of these plains, says Humboldt, are covered with herbage; others produce only evergreen saliferous plants, with fleshy and jointed stems; but a great number glitter from afar with a saline efflorescence that crystallises in the semblance of lichens, and covers the clayey soil with scattered patches like new-fallen snow.' (Dr. Traill's *Physical Geography*. pp. 21, 22.) Under the head *MIRAGE* will be found some account of a singular optical illusion often seen in the desert.

In the Old Testament the term *desert* bears a wholly different interpretation from that usually attached to it in other writings. It has been fully shown by Reland (*Palest.* l. i. p. 376) that the Hebrew מִדְבָּר (*midbar*), the *eripnos* of the Greeks, and the *desertum* or *solitudo* of the Latins bear no analogy to each other; the first being appropriated almost exclusively to those thinly peopled districts of the Holy Land which yielded pasturage for cattle, and were remarkable at once for their beauty and the luxuriance of their vegetation.

Deserter (Lat. *desertor*, from *desero*, *I forsake*). An officer, soldier or sailor, who absents himself from his duty without permission, and with the intention not to return. The crime of desertion has in all ages and countries been regarded with peculiar detestation. In Greece and Rome, the deserter, during war, suffered death; during peace, was deprived only of civil rights: a sound and enlightened distinction. The military code of Great Britain inflicts 'death or such other punishments as may be adjudged by a court-martial' on deserters; thus leaving a proper discretionary

power for the exercise of lenity in cases where the motives to the crime may bear the most favourable construction. Any soldier absent without leave for more than twenty-one days, must be tried by court-martial for desertion.

Desiccatives (Lat. *desiccō*, *I dry up*). In *Materia Medica*, applications which dry up the secretion of membranes, ulcers, &c.

Design (Fr. *dessin*, from Lat. *designo*, *I mark out*). In all the Arts, the idea formed in the mind of an artist on any particular subject, which he endeavours to transfer to some medium for the purpose of making it known to others. It is sometimes loosely and improperly used as synonymous with *drawing*.

Every work of design is to be considered either in relation to the art that produced it, to the nature of its adaptation to the end sought, or to the nature of the end it is destined to serve; thus its beauty is dependent on the wisdom or excellence displayed in the design, on the fitness or propriety of the adaptation, and upon the utility of the end. The considerations of design, fitness, and utility, have become the three great sources of beauty of form. This beauty frequently arises from the combined power of these expressions.

Every work of art supposes unity of design, or some particular end proposed by the artist in its structure or composition. In every beautiful work of art, we are not satisfied with mere utility—we must have elegant design, of which the grand feature is variety; it is this which in general distinguishes beautiful from plain forms, and without it uniformity is dull and insipid. [*DECORATION.*]

Designator (Lat.). In Roman Antiquities, the title of an officer who arranged and marshalled the funerals of distinguished persons. He was attended by a troop of inferior officers, all arrayed in black, whose part it was to keep off the crowd, like the lictors of the magistrates. (Horace, *Ep.* i. 7.)

☞ (*Desmidiūm*, one of the genera). A group of cryptogams, referred to the *Alga*. The plants are made up of a chain of connected joints, increasing by the continued addition of two new half-joints in the centre, so that the two extreme members of the chain are the oldest, and the two in the centre the youngest. Usually disarticulation takes place on the formation of the first new half-joints, in such a manner that the two new individuals consist of half the old plant connected with half of the new. Fructification (adds Mr. Berkeley, from whose account we quote) takes place, though rarely, by the conjugation of two individuals by means of lateral tubes or simple contact, the spore affecting a variety of interesting forms. The new individual is produced from this by the formation of a vertical partition in the centre, and the subsequent formation of two new half-joints, so that the proper form of the species is not attained till the third generation, if so soon. The *Desmidiaceæ*, which occur in pools, running streams, &c., differ from the *Diatomaceæ* by their green colour and

DESMINE

the absence of silex. (See Ralfs' *British Desmidia*, for a minute account of these curious plants.)

The animal nature of these organisms has been supported by Mr. Dairymple on the ground of their developing a true vitelline nucleus, transparent but molecular fluid, and a chorion or shell in their ova.

Desmine (Gr. *δεσμη*, a bundle). A variety of foliated Zeolite.

Desmology (Gr. *δεσμός*, a bond, and *λόγος*, description). That part of Anatomy which relates to tendons and ligaments.

Despot (Gr. *δεσπότης*, master). A name applied to sovereign princes possessing absolute authority. Under the Byzantine emperors, *despot* was one of five titles conferred on princes of the royal blood. (Gibbon's *Roman Empire*, ch. liii.)

Despotism. In Politics, absolute and irresponsible government by a single individual. [LIBERTY.]

Despumation (Lat. *despumatio*, from *spuma*, froth). The clarification of a liquor by skimming off the froth thrown up by boiling or fermentation.

Desquamation (Lat. *squama*, scale). The separation of layers or scales from the skin or bones.

Dessert. A word of doubtful etymology, signifying the last service at dinner, consisting of fruits, confections, &c. The modern dessert is probably equivalent to the *mensa secunda* of the Romans. If we believe Congreve, the term came into use among the French about the commencement of the seventeenth century, and was soon adopted into and naturalised in most of the European

Destemper. [DISTERPER.]

Destiny (Lat. *destinare*, to appoint). An inevitable necessity depending upon a superior cause. This doctrine has, under a variety of names, been embodied in almost all the religious systems of antiquity; and even in modern times, with a few modifications, it has been largely adopted by many sects of the Christian church. [PREDESTINATION; NECESSITY.] Destiny was called by the Romans *Fatum* [FATES], and by the Greeks *Ἀνάγκη*, *Necessity*. The Stoics understood by destiny a certain concatenation of things, which from all eternity follow each other of absolute necessity, there being no power able to interrupt their connection. To this invisible power even the gods were compelled to succumb. (Euripides, *Alc.* 965; Herodotus i. 91.)

Destructive Distillation. A term applied to the distillation of organic products at high temperatures, by which the ultimate elements are separated or evolved in new combinations. The destructive distillation of coal is resorted to for the production of gas, that of bone for the production of ammonia, and that of wood for the formation of vinegar.

Desvauxiaceae (Desvauxia, a synonym of one of the genera). A small group of mono-

DETERMINANTS

cotyledonous plants of New Holland and the South Sea Islands, having bristly leaves and glumaceous flowers. They have no particular interest.

Detached (Fr. *détaché*). In Painting, a term applied to all objects in a picture which appear to stand out or be relieved from those by which they are surrounded. It arises from a due knowledge of aerial and linear perspective.

Detached Works. In Fortification, works constructed beyond the range of the musketry of the main work.

Detachment (Fr. *détachement*). In Military language, a party of troops detached from the main body, and placed under a temporary separate command, for any special duty.

Details (Fr. *détail*). In the Fine Arts, the parts of a work as distinguished from the whole as a mass. They must always be so kept under as not to interfere with the general effect of the work; neither must they be overlaboured, lest, instead of aiding, they embarrass the work of which they form parts. [DECORATION.]

Detents. In Clockwork, the stops which lock and unlock the machinery in striking.

Detergents (Lat. *detergeo*, I wipe away). Medicines which remove viscosity, and cleanse sores.

Determinant, Functional. Any determinant whose constituents are functions of sets of variables. [HESSEAN; JACOBIAN.]

Determinants. A preliminary reference to the words **MATRIX** and **RULE OF SIGNS** will render the following definition of these important algebraical expressions at once intelligible. A determinant is the algebraical sum of the products of the principal constituents of the matrices obtained from a given square matrix, by permuting its columns (or lines) in all possible ways, the sign of each product being that which is due, according to the rule of signs, to the arrangement of columns (or lines) in the corresponding matrix. A convenient though somewhat cumbersome symbol for a determinant is obtained by writing its matrix between two vertical lines. The order, principal diagonal, constituents, principal constituents, conjugate constituents, &c. of a determinant coincide, respectively, with those of its matrix. Thus a determinant of the third order is symbolised by

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}$$

and its developed value, according to the above definition, is

$$a_1b_2c_3 - a_1b_3c_2 + a_2b_1c_3 - a_2b_3c_1 + a_3b_1c_2 - a_3b_2c_1,$$

such as

$$\begin{vmatrix} a & d & e \\ d & b & f \\ e & f & c \end{vmatrix}$$

A determinant whose conjugate constituents are equal is said to be *symmetrical*; if these conjugate constituents, however, are opposite in sign and merely equal in magnitude, the determinant is said to be *skew*; and lastly, a skew-determinant whose principal constituents are

DETERMINANTS

zeros is said to be *skew-symmetrical*. [SKW-SYMMETRICAL.]

The determinant whose matrix is obtained from that of a given determinant of the n^{th} order by omitting any m columns and any m rows is called an m^{th} *minor*, and the latter is said to have for its *complement* the $(n-m)^{\text{th}}$ *minor* formed by omitting the lines and columns that were before retained. A minor is called a *principal minor*, if its principal constituents were also principal constituents of the original determinant.

The properties of determinants are very numerous; we can here only state a few of the most elementary and important ones, referring the reader, desirous of further information, to one of the many valuable treatises on the subject which now exist, and amongst which those of Spottiswoode, *Elementary Theorems relating to Determinants*, London 1851; Brioschi, *Teoria dei Determinanti*, Pavia 1854 (translated into French and German by Combescure and Schellbach, respectively); Balzer, *Theorie und Anwendung der Determinanten*, Leipzig 1857; and Trudi, *Teoria di Determinanti*, Napoli 1862, deserve especial mention.

A determinant is not altered in value when its lines are written as columns and its columns as lines, the same order being preserved. If two columns, or two lines, are interchanged, the determinant changes its sign but not its absolute value, so that a determinant, two of whose columns or lines are alike, vanishes identically. The multiplication of the constituents of a column or line by any factor is equivalent to the multiplication of the whole determinant by that factor; for the determinant is obviously a linear function of the constituents in any column or line. From this it follows, too, that a determinant having, for constituents in any line or column, sums of the same number of terms is equal to the sum of an equal number of simpler determinants; thus

$$\begin{vmatrix} a_1 + a_1', & b_1, & c_1 \\ a_2 + a_2', & b_2, & c_2 \\ a_3 + a_3', & b_3, & c_3 \end{vmatrix} = \begin{vmatrix} a_1, & b_1, & c_1 \\ a_2, & b_2, & c_2 \\ a_3, & b_3, & c_3 \end{vmatrix} + \begin{vmatrix} a_1', & b_1, & c_1 \\ a_2, & b_2, & c_2 \\ a_3, & b_3, & c_3 \end{vmatrix}$$

The general rule for the multiplication of determinants of like order will be readily detected in the following simplest instance:—

$$\begin{vmatrix} a_1, & b_1 \\ a_2, & b_2 \end{vmatrix} \begin{vmatrix} a_1, & \beta_1 \\ a_2, & \beta_2 \end{vmatrix} = \begin{vmatrix} a_1 a_1 + b_1 \beta_1, & a_1' a_2 + b_1 \beta_2 \\ a_2 a_1 + b_2 \beta_1, & a_2 a_2 + b_2 \beta_2 \end{vmatrix}$$

and it will suffice to add that determinants of unlike orders can be multiplied by the same rule, since, without alteration of value, the order of a determinant can be easily raised.

A determinant may always be exhibited as an algebraical sum of products of minor determinants. Thus,

$$\begin{vmatrix} a_{11}, & a_{12}, & a_{13}, & a_{14} \\ a_{21}, & a_{22}, & a_{23}, & a_{24} \\ a_{31}, & a_{32}, & a_{33}, & a_{34} \\ a_{41}, & a_{42}, & a_{43}, & a_{44} \end{vmatrix} \\ = \pm \begin{vmatrix} a_{11}, & a_{12} \\ a_{21}, & a_{22} \end{vmatrix} \begin{vmatrix} a_{33}, & a_{34} \\ a_{43}, & a_{44} \end{vmatrix} \\ \pm \begin{vmatrix} a_{11}, & a_{13} \\ a_{21}, & a_{23} \end{vmatrix} \begin{vmatrix} a_{32}, & a_{34} \\ a_{42}, & a_{44} \end{vmatrix} \\ \pm \begin{vmatrix} a_{11}, & a_{14} \\ a_{21}, & a_{24} \end{vmatrix} \begin{vmatrix} a_{32}, & a_{33} \\ a_{42}, & a_{43} \end{vmatrix} \\ \pm \begin{vmatrix} a_{12}, & a_{13} \\ a_{22}, & a_{23} \end{vmatrix} \begin{vmatrix} a_{31}, & a_{34} \\ a_{41}, & a_{44} \end{vmatrix} \\ \pm \begin{vmatrix} a_{12}, & a_{14} \\ a_{22}, & a_{24} \end{vmatrix} \begin{vmatrix} a_{31}, & a_{33} \\ a_{41}, & a_{43} \end{vmatrix} \\ \pm \begin{vmatrix} a_{13}, & a_{14} \\ a_{23}, & a_{24} \end{vmatrix} \begin{vmatrix} a_{31}, & a_{32} \\ a_{41}, & a_{42} \end{vmatrix} \\ \pm \begin{vmatrix} a_{23}, & a_{24} \\ a_{33}, & a_{34} \end{vmatrix} \begin{vmatrix} a_{11}, & a_{12} \\ a_{21}, & a_{22} \end{vmatrix} \\ \pm \begin{vmatrix} a_{23}, & a_{24} \\ a_{33}, & a_{34} \end{vmatrix} \begin{vmatrix} a_{11}, & a_{13} \\ a_{21}, & a_{23} \end{vmatrix} \\ \pm \begin{vmatrix} a_{23}, & a_{24} \\ a_{33}, & a_{34} \end{vmatrix} \begin{vmatrix} a_{11}, & a_{14} \\ a_{21}, & a_{24} \end{vmatrix} \\ \pm \begin{vmatrix} a_{33}, & a_{34} \\ a_{43}, & a_{44} \end{vmatrix} \begin{vmatrix} a_{12}, & a_{13} \\ a_{22}, & a_{23} \end{vmatrix} \\ \pm \begin{vmatrix} a_{33}, & a_{34} \\ a_{43}, & a_{44} \end{vmatrix} \begin{vmatrix} a_{12}, & a_{14} \\ a_{22}, & a_{24} \end{vmatrix} \\ \pm \begin{vmatrix} a_{43}, & a_{44} \end{vmatrix} \begin{vmatrix} a_{13}, & a_{14} \\ a_{23}, & a_{24} \end{vmatrix}$$

DETERMINATE PROBLEM

where the summation sign refers to all possible products of complementary minors one factor of which is formed by omitting the first two, and the other by omitting the last two lines; the sign of each product being that which corresponds, according to the rule of signs, to the product of the principal constituents of the factors.

In the above illustration, the notation of double suffixes has been intentionally employed for the several constituents; on account of its symmetry this notation has many advantages. In connection therewith it may be remarked that the bearer a of the various suffixes may also be omitted, and the constituent in the third row and second column may be equally well represented by the symbol (32). This last method of representing quantities is in accordance with the *umbral notation* invented by Sylvester, who denotes a determinant by the more compact symbol,

$$\begin{vmatrix} 1, & 2, & 3, & \dots, & n \\ 1, & 2, & 3, & \dots, & n \end{vmatrix},$$

where the symbols in the lower line are to be permuted in all possible ways. If a_1, a_2, \dots, a_n represent any such permutation, the product $(1, a_1) (2, a_2) \dots (n, a_n)$ taken with its proper sign will obviously be a term of the determinant.

By the *determinant of the reciprocal system* is meant one whose constituents are, respectively, the first minors which, in a given determinant of the same order, appear as coefficients of the corresponding constituents. Such a determinant is always equal to the $(n-1)^{\text{th}}$ power of the given determinant, and any m^{th} minor of it is equal to the $(m-1)^{\text{th}}$ power of the original determinant multiplied by the complement of the corresponding m^{th} minor of the original system.

With respect to the history of determinants, any one of the before-mentioned treatises, and especially that of Balzer, may be consulted. We cannot conclude this short notice, however, without reference to Jacobi's two important memoirs, entitled *De Formatione et Proprietatibus Determinantium* and *De Determinantibus Functionalibus*, the appearance of which in Crelle's *Journal* marked an epoch in the progress of mathematics. According to the notation employed by this author, a determinant is represented by the symbol

$$\Sigma \pm (a_1' a_2'' a_3''' \dots a_n^{(n)})$$

the summation sign being supposed to extend to all possible permutations of the affixes or suffixes, and the sign of each term being determined as before.

Determinate Problem. In Geometry, a problem which admits of a *limited* number of solutions; an *indeterminate problem* being one which admits of an indefinite number of solutions. Thus the problem, *Given the base, perimeter, and area, to construct the triangle*, is determinate, there being, in general, but four solutions. By omitting one of the three data, however, the problem becomes indeterminate. For instance, an infinite number of triangles

DETERMINATIVES

having the same perimeter can be constructed on a given base. Nevertheless the problem is not perfectly indeterminate, for the vertices of all such triangles are restricted to a certain locus, viz. the ellipse whose foci are the extremities of the given base. In general, the omission of one of the conditions or data which render a problem determinate leads to a *local problem*.

Determinatives (Lat. *determino, I mark off*). Ideographic signs annexed to a word expressed by phonetic signs, for the purpose of defining its signification. Thus a figure of a tree is in the Egyptian hieroglyphics determinative of the name of trees; but the figure so employed does not express the word of which it is the symbol. In the words of Baron Bunsen, 'it only determines the meaning of the preceding phonetic sign, the sense of which would otherwise remain doubtful to the reader, owing to the various significations of the same Egyptian roots.' (*Egypt's Place in Universal History* i. 263-5.) [ALPHABET.]

Detinue. In Law, a personal action of contract, which lies where a party seeks to recover goods and chattels, or deeds and writings, detained from him. [PLEADING.]

Detonating Powder. A term applied in Chemistry to fulminating mercury and silver, and to other compounds which suddenly explode when struck or heated. Some of these compounds have lately been much used for the ignition of gunpowder in percussion locks, and in the fuzes of shells for rifled guns.

Detonating Tube (Lat. *detono, to thunder*). A stout glass tube used in the chemical laboratory for the detonation of gaseous bodies. It is generally, as represented in the annexed cut, graduated into centesimal parts, and perforated by two opposed wires for the purpose of passing an electric spark through the gases which are introduced into it, and which are confined within it over water or mercury. When a detonating tube is used over either of these fluids, the smallest possible quantity of explosive gas should be introduced into it, as, in consequence of the expansion which ensues, a portion is apt to be forced out at the moment of the explosion. The tube, when used, should be firmly held; a spring is sometimes substituted for the grasp of the hand, but it is inconvenient.

Detonation. When chemical combination or decomposition is sudden and attended by flame and explosion, it is often said to be effected by *detonation*. If a mixture of hydrogen and oxygen be inflamed by the electric spark or by a taper, it burns rapidly and with explosion, and is said to *detonate*. When a grain or two of phosphorus is mixed with chlorate of potassa and struck with a hammer, the mixture detonates.

Detritus (Lat. *part. of detero, I rub off*). A term used in Practical Geology to express the minute portions of a rock, or a deposit, which

DEVELOPABLE SURFACE

may have been detached and removed to a distance by the action of any abrading power.

Detrusion (Lat. *detrudo, I thrust aside*). The action of any force to thrust outwards a body exposed to its influence; as in the case of an embankment behind a retaining wall; or of an arch, or a truss, acting upon a pier, or other point of support intended to receive its effect. The word *detrusion* is in fact nearly synonymous with the expression *outward thrust*; and in most cases it may be conveniently substituted for it.

Deucalion. In Greek Mythology, the son, according to the Hesiodic Catalogue, of Prometheus and Pandora, and the husband of Pyrrha, who with him alone escaped the great deluge which overwhelmed the land in the reign of Ogyges. (Grote's *History of Greece*, part i. ch. v.)

Deus ex Machinâ (Lat.). A scholastic expression, borrowed from the stage. By a certain machine, the gods were represented as flying in the air. When any such intervention, contrary to the maxim of Horace,

Nec deus interst nisi dignus vindice nodus,

took place without an adequate cause, it was condemned as injurious to scenic effect. Hence the proverb, which has also been applied by analogy to those philosophers who, unable to solve a difficulty by ordinary means, have immediate recourse to the aid of a supernatural power.

Deuteronomy (Gr. *δεύτερον νόμον, the second law*). The name given to the last book of the Pentateuch. It is equivalent to the *Mishna* of the Hebrews, who thus designated the book of Deuteronomy, from its containing a recapitulation of the laws and ordinances scattered over the other books of Moses. [PENTATEUCH.]

Deuteropathia (Gr. *δευτερος, second, and πάθος, disease*). A sympathetic affection of any part; as a headache from an overloaded stomach, or sickness from an injury of the head.

Deutoxide. A term applied in Chemistry to certain compounds containing *one* atom or equivalent of base in combination with *two* of oxygen; in this sense the word is synonymous with *binoride*. It is sometimes indiscriminately applied to the second degree of oxidisation of which bases are susceptible.

Developable Helicoid. [HELICOID.]

Developable Osculatrix. The developable surface generated by the tangents of a non-plane curve. Every tangent plane of the surface is an osculating plane of the curve. [CURVE.]

Developable, Polar. [POLAR DEVELOPABLE.]

Developable Surface. A ruled surface, the consecutive generators of which intersect each other. [RULED SURFACE.] The non-plane curve generated by the successive intersections of these generators is called the *cuspidal edge* or *edge of regression of the surface*—since every plane section of the developable has a cusp at the point where its plane meets this curve.

DEVELOPEMENT

The plane of two successive generators is clearly a tangent plane of the surface, and an osculating plane of its cuspidal edge. It touches the surface at every point of the generator: if we conceive it to be turned around this generator as a hinge until it coincides with the next tangent plane, and these coincident planes to be turned similarly around the next generator, it is obvious that the whole surface may, without crumpling or tearing, be unfolded into a plane; hence the term *developable*. Such a surface may also be regarded as the envelope of a plane which satisfies any two conditions, and whose equation $u=0$ therefore contains one variable parameter α . The equation of the developable envelope of the plane $u=0$ is obtained by eliminating α from the equations $u=0$ and $\frac{du}{d\alpha}=0$; the equations of its cuspidal edge result in like manner from the elimination of α from $u=0$, $\frac{du}{d\alpha}=0$, $\frac{d^2u}{d\alpha^2}=0$. Lastly, the elimination of x, y, z

from the last three equations and $\frac{d^2u}{d\alpha^2}=0$ gives

an equation in α whose roots correspond to tangent planes which are met by three consecutive ones in the same point; the latter will be a stationary point on the cuspidal edge. [ENVELOPE.] In like manner a developable may have one or more stationary tangent planes, that is to say tangent planes each of which coincides with the consecutive one. The number of generators which meet a given line determines the *order* of the developable, which is obviously the same as the *class* of its cuspidal edge. [CURVE.] Further, the number of tangent planes which pass through a given point defines the *class* of the developable; thus, the degree in which α enters into the equation of the plane $u=0$ is the *class* of the developable if envelopes. Every generator of a developable will, in general, be intersected by a number of other non-consecutive generators in points which form a *nodal* or *double curve* of the surface. The order of this curve and the other singularities of the surface may be ascertained, as Cayley has shown (*Cambridge and Dublin Mathematical Journal*, vol. v.), by aid of Plücker's equations connecting the singularities of plane curves. The Hessian of a developable is reduced to zero by the coordinates of every point of the surface, and must consequently contain the equation of that surface as a factor. The remaining factor, of the $(3n-8)^{\text{th}}$ degree, is called the *Pro-Hessian*. The Hessian equated to zero is equivalent to the partial differential equation

$$\frac{\partial^2 z}{\partial x^2} \frac{\partial^2 z}{\partial y^2} - \left(\frac{\partial^2 z}{\partial x \partial y} \right)^2 = 0,$$

which is satisfied by every developable.

Development (Fr. *développement*, an unfolding). The stages which an animal passes through before arriving at the epoch of fecundation or *Gamomorphie* period, are termed stages of development. The law was first

DEVIATION OF THE COMPASS

enunciated by John Hunter, that each of the higher animals during its embryo phases passes through stages which are persistent in the lower animals of the same subkingdom to which it belongs. Thus, the human embryo adopts at its earliest period the aspect of a ciliated monad or infusory; and from that stage passes through phases analogous to, though not absolutely identical with, those of the lower vertebrata. This law, as well as that of Parthenogenesis, has been urged as demonstrating the existence of a constantly operating secondary law, which has produced the various diversified and specialised animal forms. The more generalised structure of many of the extinct animals, e.g. *Archegosaurus*, *Anoplotherium*, as compared with the fauna of the present day, in which functions once performed by one individual or set of organs are now distributed amongst several genera and more diversified structures, are examples of the law that the special forms have now superseded the more generalised or embryonic forms in the developmental scale.

DEVELOPEMENT. In Theology, a phrase which has of late years obtained some currency, chiefly in England, through the famous *Essay* of Dr. J. H. Newman, written to explain his view of the general bearing of Roman Catholic doctrine at the time when he went over to that church. According to its theory, a dogma, not in express terms promulgated nor distinctly known to the early church, may become established by the church and received as matter of faith in later times, provided only, when thus expanded, it is in real accordance with the less complete views attained at an earlier period by the same continuing authority. As, for instance, the dogma of the supremacy of the see of Rome is one of which the full 'development' was reserved for later times, although all that remains to us on the subject, from the tradition of earlier times, is, according to this theory, in consistency with it.

Deviation of the Compass. The variation of a ship's compass from the true magnetic meridian is caused by the near presence of iron, and in iron ships depends upon the direction, with regard to the magnetic meridian, in which the ship was built. This subpolal magnetism of the ship, caused by the hammering of the plates, runs down, as it were, very rapidly, and necessitates frequent corrections. It is least when the ship has been built, as to magnetic meridian, head south. Armour-plated ships should be plated with the head in the opposite direction to that of building.

There are two methods in practice by which this variation is attempted to be neutralised: the first is by ascertaining the actual variation in every position of the ship with regard to the magnetic meridian and working by a table of errors; the other is by introducing on board ship masses of iron and magnets to neutralise exactly the action of the ship's magnetism. The latter method, which corrects the compass, now very generally employed, and has many

DEVIL

advantages. To accomplish it, the ship's head is placed magnetic north or south by the aid of a shore compass viewing her masts; a magnet is placed on the ship's deck in an athwart position ahead or astern of the compass, and is slid nearer or farther till it causes the compass to point correctly. The ship is then placed magnetic east or west, and another magnet is placed in a fore and aft position on the deck on one side of the compass, and is slid nearer or farther till it causes the compass to point correctly. The magnets do not interfere with each other's action. The ship is lastly placed in an intermediate position, and a mass of iron is placed on one side of the compass to correct quadrantal deviation. It is of very great importance that the ship should not be hurried out immediately for a long voyage, but that she should be exposed to tremors for some days, and that her compasses should be readjusted before sailing on a long voyage.

For further information, see *Admiralty Manual*, and *Proc. Roy. Soc.* April 1865.

Devil (Ger. *teufel*, Fr. *diable*, generally connected with Gr. *διδσκαλος, an accuser*) This word bears the same sense as *Satan*, and is applied in the New Testament to the evil principle, the adversary of man referred to throughout the Old and New Testaments, under various names and titles, as *Satan*, *Lucifer*, *Belial*, *Apollyon*, *Abaddon*, the *Man of Sin*, the *Tempter*; and described as an angel who fell from heaven with many inferior spirits, being cast down thence by God for his pride and rebellious spirit. From that time he is said to have had permission to try and tempt mankind. He is represented in *Job* and *Zechariah* as standing in the presence of the Lord, seeking permission to tempt men. The character herein attributed to the Devil is identical with that of the *Evil Principle* in the Gnostic philosophy; excepting indeed that the Scriptures always maintain the inferiority of the evil to the good. [DEMON; POSITIVISM; VITRA.]

DEVIL. In Printing, formerly the boy who took off the sheets as printed from the tympan of the press; they, as old Moxon says, 'do in a printing house commonly black and bedaub themselves; whence the workmen do jocosely call them *devils*.' The term is now applied to the *messengers*.

Devil's Dung. An old pharmaceutical name of *assafoetida*.

Devilline. The name given by M. F. Pisani to a newly discovered mineral, in honour of M. H. Sainte-Claire Devilla. It is a hydrated subsulphate of copper with about 8 or 10 per cent. of lime, which, doubtless, partly replaces the copper. It is found in Cornwall, in the form of very pale bluish-green tender crusts, composed of exceedingly small crystalline laminae: the crusts having externally an earthy appearance, but a silky lustre on fractured surfaces.

Devise or Device (Fr. *deviser, to invent, will, or imagine*). In Heraldry, the term *devise* is popularly used in the same sense as *ARMORIAL*.

DEVONIAN SYSTEM

BEARINGS [which see]; but it is more strictly employed to signify a symbol, consisting of a representation of some visible object, and in many instances a motto appropriate to it, used, not by way of heraldic bearing, but according to the fancy of the inventor: sometimes for the motto alone.

DEVISE (Fr. *deviser*, in its old meaning, *to will*). In Law, is a gift of lands by a last will and testament. Lands held in fee-simple became devisable, where not so by special custom, by the statute 34 & 35 Hen. VIII. c. 5. By 3 & 4 Wm. & Mary, c. 14, devises were made void against specialty creditors. Estates *pur autre vie* became devisable by stat. 29 Ch. II. c. 3. A will of lands formerly only operated on those lands of which the testator was possessed at the time of publishing it. [WILL.] But by the present Statute of Wills (1 Vict. c. 26) every will is held to speak, both as to real and personal property, as if executed immediately before the death of the testator.

Devitrification (Lat. *vitrum, glass*). A peculiar change which takes place in glass, in consequence of the action of certain decomposing agents. Thus glass long exposed to ammoniacal fumes, or which has been long acted upon by water, is subject to this change. It is characterised by the surface becoming dull and earthy; its losing transparency, and assuming a kind of opaline iridescence; it also becomes more fibrous, and less brittle, than ordinary glass. Some glass vessels discovered in Greek, Roman, Egyptian, and Assyrian tombs bear marks of this kind of decay.

Devonian System. One of the local names now frequently adopted to designate a particular phase of the middle member of the great Palaeozoic series of rocks as developed in the northern hemisphere, and chiefly in the western part of it.

Although recognised as belonging to an early period of the earth's history, the calcareous grits, impure limestones and flags, and the calcareous slates and limestones of various parts of Devonshire, were long misunderstood, and the so-called 'old red sandstone' of Herefordshire and Scotland was for some time described by English geologists as the only group of rocks separating the carboniferous from the recently described Silurian series. Important groups of slates and limestones, not unfossiliferous, were known to exist in the Eifel and near the banks of the Rhine; but these were not, at the time we speak of, identified with deposits already occupying a recognised position in the geological series.

Under these circumstances the proof obtained by Sir R. Murchison and Professor Sedgwick, that these Devonian rocks were contemporaneous both with the old red sandstone and with the Eifel series, was a great step in advance, and tended to fix very important positions in geological classification. The subsequent discovery of the conglomerates of the old red sandstone, and the fossiliferous rocks of Devonshire and the Rhine, side by side, or

alternating with each other in Russia, was one of the many valuable observations which geology owes to Sir R. Murchison.

The Devonian beds, strictly so called, are generally fossiliferous, and sometimes richly so; but the condition of the fossils in England is usually very bad. The lower portion of the series consists of the Plymouth and other limestones in the south, loaded with corals, and represented by coarse grits in the north of Devon and the Cornish slates. Overlying these are red flags and slates. Sometimes other limestones at the top intervene between these and the culmiferous bed of the carboniferous system. [CARBONIFEROUS SYSTEM.]

Normandy presents Devonian rocks in a characteristic state, and they are traceable at intervals along the north of France into Belgium, where they form part of the great Rhine and Nassau series. The Russian Devonians occupy a tract nearly as large as Great Britain, lying on Silurian rocks rising nearly 1,000 feet above the sea, and apparently unaltered. In various parts of North America, and even in South America and Australia, Devonian formations recur.

Metalliferous veins are abundant in the Devonian slates and schists of Devon and Cornwall, and near the contact of these with granite. Copper is the principal metal; but argentiferous galena and blende are common in certain parts of the district. [OLD RED SANDSTONE and PALÆOZOIC.]

Devonite. A mineralogical synonym of the *Wavellite* or *Hydargyllite* which is found at Barnstaple in Devonshire.

Dew (Ger. *thau*). The deposition of water from the atmosphere, occasioned by cold. The phenomena of dew have been considered by all writers on meteorology, from Aristotle downwards; but they were first successfully investigated by Dr. Wells in 1814.

The circumstances which influence the production of dew are the following: Dew is never abundant except during calm and serene nights. It is, however, frequently observed in small quantities, on windy nights if the sky is clear, and on cloudy nights if there is no wind; but it is never seen on nights which are both cloudy and windy at the same time. If, in the course of the night, the weather, from being calm and serene, should become windy and cloudy, not only will no more dew be formed, but that which has been already formed will disappear, or at least diminish considerably. In calm weather, if the sky be partially covered with clouds, more dew will appear than if it were entirely covered, but less than if it were entirely clear. A very slight motion of the air is rather favourable than otherwise to the formation of dew. On two nights equally calm and serene, the quantities of dew deposited may be very unequal. If rain has fallen recently, it will be formed in abundance; on the contrary, very little will be formed in nights otherwise favourable, if the weather has been dry for some time previously. In general, what-

ever tends to increase the quantity of moisture in the atmosphere will contribute to render the deposition of dew more abundant. Dew is commonly more plentiful in spring and autumn than in summer; the reason is, that the differences of the temperatures of the day and night are greater in the former seasons of the year than in the latter. It is always most copious on those clear and calm nights which are followed by misty or foggy mornings; the formation of the fog showing that the atmosphere had previously contained much moisture. It is unusually plentiful on a clear morning succeeding a cloudy night. The notion that dew is only formed in the morning and evening is incorrect; bodies are covered with dew at all hours of the night, provided the sky be serene. In this country dew generally begins to appear upon grass, in places shaded from the sun, during clear and calm weather, soon after the heat of the atmosphere has declined; that is, three or four hours after midday. Grass is frequently felt to be moist, in dry weather, several hours before sunset; but dew is scarcely ever formed in visible drops before the sun is near the horizon, and is never copious till some time after sunset. Other circumstances being equal, less dew is formed during the first half of the night than during the second, although the air, at midnight, has already lost a certain portion of its moisture.

Polished metals attract the least quantity of dew; and when formed upon them, it will often disappear, while other substances in the neighbourhood remain wet; and a metal which has been purposely wetted will often become dry, though similarly exposed with bodies that are contracting dew. This inaptitude of the metals to attract dew is communicated to bodies of a very different nature which touch or are near them: for example, wool laid upon a metal will acquire much less dew than an equal quantity laid upon grass in the immediate vicinity; and, conversely, bodies on which the metals are laid have an influence on the quantity of dew which the latter will attract. The metals do not all resist the formation of dew with the same force. Dr. Wells one night saw platinum distinctly dewed, while gold, silver, copper, and tin, though similarly situated, were entirely dry; and he several times saw these four metals free from dew, while iron, zinc, and lead were covered with it.

Difference in the mechanical state of bodies, though the other circumstances be similar, has an effect on the quantity of dew which they attract. Thus, more dew is formed upon fine shavings of wood, than upon a thick piece of the same substance; and raw silk, cotton and flax, were found to attract more dew than the woove material.

The quantity of dew precipitated on bodies is also influenced by their situation in regard to surrounding objects. As a general principle, it may be affirmed that whatever tends to diminish the portion of the sky which can be seen from the place which the body occupies,

diminishes the quantity of dew with which it will be covered.

Of the Cold connected with the Formation of Dew.—The temperature of grass covered with dew is always lower than that of the surrounding air. On calm and clear nights, Dr. Wells frequently found the grass 7° , 8° , or 9° , and on one occasion 14° , colder than the air about four feet above it. He also observed that in places sheltered from the afternoon sun, but still open to a considerable portion of the sky, the difference between the temperature of the grass and the air begins to be sensible as soon as the heat of the atmosphere begins to diminish. In analogous circumstances, a similar coldness continues on grass, in still and serene mornings, for some time after the rising of the sun. In cloudy nights, particularly if there was wind, the grass was never much colder than the air; sometimes it was even warmer: but in calm weather, very high clouds, though sufficiently extensive and dense to conceal the sky, would yet frequently allow of the grass being several degrees colder than the air. If the night became cloudy, after being very clear, the temperature of the grass immediately became higher. The temperature of metals sometimes falls from 2° to 4° below that of the surrounding air; when this takes place, other bodies, such as wool, swan-down, the leaves of plants, &c., are considerably colder than the atmosphere. The substances which are most easily covered with dew are those which are cooled down the quickest when exposed to a clear sky. Of the substances tried by Dr. Wells, swan-down and other filamentous and downy materials exhibited the greatest cold.

Theory of Dew.—Dr. Wells's experiments show that the most perfect analogy subsists between the faculty which bodies possess of attracting moisture from the atmosphere, and the other property which they have of acquiring, in calm and clear nights, a temperature much below that of the surrounding air. But is the cold, which is observed on bodies covered with dew, the cause or the consequence of its precipitation? The latter opinion was maintained by Dr. Wilson of Glasgow, in a paper on hoar-frost inserted in the first volume of the *Transactions of the Royal Society of Edinburgh*. But it has been clearly established by Dr. Wells that the cold is the cause of the dew; for he found, 1st, that in certain circumstances bodies would become colder than the air without being dewed, whence it is obvious that the cold could not be the effect of the dew; and, 2nd, that when dew was formed, its quantity and the degree of cold that appeared with it, at different times, were very far from being always in the same proportion to each other. He also invariably found that bodies became colder before dew began to appear on them. The formation of dew is therefore a phenomenon precisely of the same kind as the precipitation of moisture which takes place on the outside of a vessel into which a liquid colder than the air

is poured. It is well known that atmospheric air, at every different degree of temperature, can contain only a determinate quantity of water, and that the quantity is greater as the temperature is higher. If, then, a stratum of air has its temperature lowered by coming into contact with a body colder than itself, a portion of its water will immediately be precipitated. A second stratum of air succeeds the first, is cooled down in its turn, and abandons that portion of its moisture which its decreased temperature does not permit it to retain. The phenomenon is repeated with great rapidity, and in a short time the cooling body is covered with dew or moisture. As soon as it was proved that bodies exposed to the clear sky acquire a temperature lower than that of the adjacent atmosphere, the origin of the moisture with which their surfaces become covered could not be mistaken.

In order to render this theory complete, it only remains to explain the cause why bodies, when exposed to the cloudless sky in clear and calm nights, become colder than the surrounding atmosphere. Since the laws of the radiation of heat were established by the experiments of Leslie and Rumford, the rationale of this phenomenon has been well understood. During calm and serene nights, the upper parts of the grass radiate their heat into the regions of space, from which they receive back no heat in return; its lower parts, from the smallness of their conducting power, transmit little of the earth's heat to the upper parts, which at the same time receiving only a small quantity from the atmosphere, and none from any other lateral body, must remain colder than the air, and condense into dew its watery vapour, if this be sufficiently abundant.

This explanation is grounded on the hypothesis of M. Prevost, of Geneva, respecting the constant radiation of heat by bodies in contact with the atmosphere, even at the time when they are exposed to the influence of bodies warmer than themselves: but the hypothesis has not been universally admitted; and Sir J. Leslie, on the contrary, ascribes the effect to the descent of cold air from the upper regions of the atmosphere. 'The application of the æthrioscope,' he remarks, 'has not only ascertained the existence, but measured the intensity, of the cold pulses which are at all times darted downwards from the successive strata of air, though often partially intercepted by clouds, or more completely obstructed by low fogs. It may be computed that in fine bright evenings those cold pulses, ruined from the sky, are sufficient alone to depress the temperature of the ground, according to the seasons, sometimes eight degrees, but generally about three degrees of Fahrenheit's scale. The blades of grass, thus chilled from exposure, cool in their turn the damp air which touches them, and cause it to drop its moisture.' (*Encyclopædia Britannica*, art. 'Dew.')

It may be added, that among all the phenomena connected with the formation of dew, there is not one which does not admit of a satisfactory explanation on the principle esta-

DEW POINT

published by Dr. Wells; namely, that dew is never deposited on the surface of bodies till they have been previously cooled by their radiation towards space.

Dew Point. The degree indicated by the thermometer when dew begins to be deposited from the air. The instruments used for the determination of the dew point are termed **HYGROMETERS** [which see].

Dewberry. The fruit of *Rubus cæsius*, so termed from the resemblance which the bloom or waxy secretion upon its surface bears to dew.

Dexiarisee. A family of Dipterous insects, which subsist chiefly on the juices of flowers. The typical genus is *Dexia*; the other genera included in the family are *Teuxia*, *Dinera*, *Scotiptera*, *Rutilla*, *Gymnostyla*, *Omalogaster*, and *Proserna*.

Dextrin (Lat. *dextra*, the right hand). In Chemistry, means the soluble or gummy matter into which the interior substance of starch globules is convertible by *diastase*, or by certain acids. Its chemical formula is $C_{12}H_{10}O_{10}$. It is remarkable for the extent to which it turns the plane of polarisation to the right hand, whence its name. The term is also applied to starch which by exposure to heat has been rendered soluble in cold water. This artificial or *British gum*, as it has sometimes been termed, is largely used as a substitute for gum arabic. It is employed for stiffening calicoes, for sizing paper, and for the adhesive layer at the back of postage stamps. Starch is also converted into dextrin by the action of the saliva, pancreatic juice, and some other fluids.

Dextroracemic Acid. *Dextrotartaric acid*. The ordinary tartaric acid of commerce is so called because it causes right-handed rotation of a ray of plane polarised light.

Dey (derived by some from the Turkish *dai*, a maternal uncle). A Turkish title of dignity, given to the governors of Algiers (before the French conquest), Tunis, and Tripoli. The dey is chosen for life from among the chief authorities of the place, with the approbation of the Turkish soldiery. At Tunis the equivalent title of *bey* is more usually substituted for *dey*.

Diabase. A mineralogical synonym of greenstone.

Diabetes (Gr.). An immoderate flow of urine. There are two varieties of this disorder; the one is merely a superabundant discharge of ordinary urine, and is termed *diabetes insipidus*; in the other the urine has a sweet taste, and contains abundance of that modification of saccharine matter termed *glucose*: it is called *diabetes mellitus*. This disease usually attacks persons of a debilitated constitution towards the decline of life, and generally without any obvious cause. Thirst and a voracious appetite are its first symptoms; the urine gradually increases in quantity; and then there is a sense of weight and uneasiness in the loins, emaciation, œdematous legs, and hectic fever. In *diabetes mellitus* the quantity of saccharine matter is generally such, espe-

DIACOPE

cially where the disorder has been of long standing, as materially to increase the specific gravity of the urine; and this accordingly forms a useful criterion of the state of the disease, for whatever tends to diminish the specific gravity of the urine is at the same time diminishing its saccharine contents: an hydrometer therefore is useful in determining this point. The specific gravity of healthy urine does not exceed 1020, and contains about 380 grains of solid matter in the pint; that of diabetic urine sometimes attains a specific gravity of 1040 to 1060; in which case, as appears from Dr. Henry's table (*Medico-Chirurgical Transactions*, vol. ii.), it contains from 766 to 960 grains of solid matter in the pint. The cause of this disease is unknown; nor has dissection thrown much light upon it, for in some cases no morbid state of the viscera is observed; in others, however, the kidneys are flabby, pale, and enlarged, or more vascular than they should be: the lacteals are also sometimes thickened, and the mesenteric glands enlarged. There are very few cases on record of the cure, or even of the relief, of confirmed diabetes. Where it is symptomatic of hysteria, dyspepsia, or hypochondriasis, the usual remedies for those affections are useful; but where it is *idiopathic*, and saccharine, nothing has proved decidedly serviceable. Strict abstinence from vegetable food of every kind, and the free exhibition of opium, are the only plans which have held out hopes of success; but there are very few cases upon record in which these seem to have been permanently successful.

Diacaustic Curve. In the Higher Geometry, the *caustic by refraction*. It is generated as follows: If rays Pm issuing from a luminous point P be refracted by the curve Amb , so that the sines of incidence are to the sines of refraction in a given ratio, the curve CDH , which touches all the refracted rays, is called the *diacaustic*, or caustic by refraction. [CAUSTIC.]

Diachylum or **Diachylon** (Gr. *διαχυλος*, juicy). A celebrated plaster of former days made of the juices of several plants; the term is still retained, and applied to common plaster, made by boiling hydrated oxide of lead with olive oil.

Diadolosite (Gr. *διακλω*, to cleave in two). A variety of Augite, intermediate in composition between Diallage and Hypersthene. It is found in Bavaria; in the Harz; and in the Guadarama Mountains of Spain.

Diacodium (Gr. *δια*, and *κωδια*, a poppy). A preparation of the poppy. Syrup of white poppies was formerly called *syrup of diacodium*.

Diacopec (Gr. *a gash or cut*). A genus of spiny-finned fishes of the Perch tribe, allied to *Serranus*; but distinguished by a notch at the

lower part of the preoperculum, to which a projecting tubercle is adapted.

Diacoustics (Gr. *διά*, and *ἀκούω*, *I hear*). That branch of Physics which treats of the properties of sound refracted in passing through media of different densities. [SOUND.]

Diacritic Marks (Gr. *διακριτικὸς*, *able to distinguish*). In Palæography, marks used to distinguish letters, between the forms of which much similarity exists. Thus *n* and *u* are distinguished in German running hand by the mark *u* over the latter letter.

Diadelphous (Gr. *δίς*, and *δελφύς*, *a womb*). In Botany, a term applied to stamens the filaments of which have coalesced into two masses or brotherhoods, as in *Fumaria* and many leguminous plants.

Diadem (Gr. *διδήμα*, from *δέω*, *I bind*). Originally a fillet wound round the temples, probably imported into Greek costume from the East. It was the symbol of royalty among various Oriental nations. The diadem of Bacchus, from the representation in ancient statues, &c., was a broad band, which might be unfolded so as to form a veil. Constantine the Great was the first Roman emperor who used the diadem; after his time, it was set with rows of pearls or precious stones.

Dicresis (Gr. *διάρσις*, from *διαίρω*, *I divide*). In Grammar, the resolution of a diphthong, or a contracted syllable, into two syllables: as in Latin, *aurai* for *auræ*, &c.; and, in English, the resolution of the last syllable of participles by giving a sound to the final *e*; *belovéd*, *curséd*, &c. [METAPLASM.]

Diagnosis (Gr.). The art of distinguishing one disease from another. The characteristic symptoms of diseases, by which they are recognised, are termed their *diagnostic symptoms*.

Diagometer (from Gr. *διάγω*, *I lead through*, and *μέτρον*). An electric instrument for determining the conducting power of fixed oils, and especially for the detection of adulteration of olive oil, which is said to have the lowest conducting power of such oils.

Diagonal (Gr. *διαγώνιος*, from *γωνία*, *an angle*). A straight line drawn through a figure, joining two opposite angles. The term is chiefly used in Geometry, in speaking of four-sided figures; but it is also properly applied with reference to all polygons of which the number of sides is not less than four. Euclid uses the term *diameter* in the same sense; but modern geometers use *diameter* only when speaking of curve lines, and *diagonal* when speaking of angular figures. [QUADRANGLE and QUADRILATERAL.]

Diagonal Eye-piece. An eye-piece used in sun-observations. [EYE-PIECE.]

Diagram (Gr. *διάγραμμα*, from *διά*, *through*, and *γράφω*, *I write*). The figure or scheme drawn for the illustration of a mathematical proposition, or the demonstration of any of its properties.

Diagridium or **Dacrydium** (Gr. *δακρύδιον*, dim. of *δάκρυ*, *a tear*). An obsolete name

of scammony in drops or tears, and of some old preparations containing that drug.

Dial or Sun-dial. An instrument for showing the hour of the day by means of the sun's shadow. The invention and use of sundials are of the highest antiquity. According to Herodotus, the Greeks learned the use of them from the Chaldeans; and the first of which history makes mention is the hemisphere of Berosus, who is supposed to have lived about 540 years before Christ. The sun-dial and the clepsydra were the only instruments known to the ancients for the measurement of time.

In constructing a sun-dial, the object is to find, by means of his shadow, the sun's distance at any time from the meridian. When this distance is known, the hour is also known, provided we suppose the sun's apparent motion to be uniform, and that during the whole course of a day he moves in a circle parallel to the equator. Neither of these conditions is, in fact, accurately fulfilled, but the error which this gives rise to is of small amount; and it is, moreover, sufficiently obvious that the use of a dial is not to indicate the hour with astronomical precision, but merely to give such an approximation as is necessary for the purposes of civil life.

Dials are usually constructed on an immovable surface, and admit of an infinite number of different constructions, all depending on the nature of the surface and its position with regard to the equator of the earth. The general principles, however, are the same in all, and depend on the simplest elements of geometry and astronomy. The first part that claims attention is the *style* or *gnomon*, or axis of the dial, which is usually a cylindrical rod, or the edge of a thin plate of metal. The style must be parallel to the earth's axis; and being so, it may be considered, on account of the smallness of the earth's diameter in comparison of the distance of the sun, as coinciding with the axis of the diurnal rotation; consequently the plane which passes through the centre of the sun, the style, and its shadow if a rod, or the limit of shadow of an edge, will be an *hour plane*, and turn with the sun, as the sun turns round the style by the effect of the diurnal motion. All that remains to be done, in addition, is to discover, and describe, for the different hours of the day, the intersections of this variable hour plane with the surface on which the dial is to be constructed. On these intersections the shadow of the style will be projected every day at the same hour; because at the same hour the sun returns daily to the same hour plane, although his distance from the equator may be different.

From these considerations it is manifest that the whole theory of dialling is comprehended in the solution of this general problem: 'Twelve planes all intersecting each other in the same straight line, and making with each other equal angles of 15°, being given in position; to find the intersections of those planes with any sur-

DIAL

face whatever, also given in form and position.' The surface which intersects the hour planes may be of any kind whatever, but for obvious reasons it is generally a plane; and when its position with respect to the common intersection of the hour planes (which is the style of the dial) and to any one of those planes is given, the *traces* or intersections, which are in this case all straight lines, are the *hour lines* on the dial, and easily determined by the ordinary rules of trigonometry or geometry.

According to the position of the plane of the dial with respect to the horizon of the place, the dial is *horizontal*, *vertical*, or *inclined*. The simplest case of all is that in which the plane of the dial is parallel to the axis of the earth, and perpendicular to the meridian of the place. In

the plane of the dial, and the hour lines are parallel straight lines, whose distances from the meridional line are respectively proportional to the tangents of the angles which the hour planes make with the plane of the meridian. This is called a *Polar Dial*.

The most common construction is the *Horizontal Dial*, or that in which the plane of the dial is parallel to the horizon, and consequently makes with the style an angle equal to the latitude of the place. At the equator, this is the same as the polar dial, which has just been described; but at all other places, the hour lines intersect each other in the point in which the style intersects the plane of the dial, which point is called the *centre*, and the angles they make with one another, or with the meridional line to XII, depend upon the latitude. The following table shows the angles which the different hour lines of a

horizontal dial make with the meridional line, at the latitude of London, or $51\frac{1}{2}^\circ$:—

Morning	Afternoon	
XI.	I.	11° 51'
X.	II.	24 19
IX.	III.	38 3
VIII.	IV.	53 35
VII.	V.	71 6
VI.	VI.	90 0

After the horizontal dials, the construction most frequently employed is that in which the plane of the dial is vertical; for example, when fixed on the wall of a house. In this case, the positions of the different hour lines depend on the latitude of the place and on the aspect of the dial; that is to say, its position with respect to the meridian. If the dial is perpendicular to the meridian, it is a *south dial*, or *north dial*, according as it faces the south

DIALECT

or north. (The vertical south dial is represented in the annexed figure.) When not perpendicular to the meridian, the vertical dial is said to be *declined*. The determination of the

hour lines on a south vertical dial is precisely the same as in the case of the horizontal dial. The only difference is that the angle between the style and the plane of the dial is now equal to the complement of the latitude; whence it follows that a horizontal dial constructed for any given latitude will be a south vertical dial for any place of which the latitude is the complement of the latitude of the former place—a property which was discovered by the Arabians. The hour lines of the vertical north dial are found exactly in the same way as those of the south dial.

When the face of the vertical dial is exactly east or exactly west, its plane is in the meridian, and consequently parallel to the vertical plane in which the style is. The hour lines, therefore, as in the polar dial, are all parallel to one another, the only difference being that in the present case there can be no hour line corresponding to noon, since at that time the hour plane is parallel to the plane of the dial.

When the vertical dial does not face directly one of the four cardinal points, it is called a *declining vertical dial*, and the investigation of the hour lines is somewhat more complicated.

It will be observed that the time indicated by a dial is *solar* time or *true* time, and agrees with *mean* time, or that which is shown by a well-regulated clock, only on four different days of the year. [EQUATION OF TIME.]

It has been supposed that the style is formed by a wire, or the straight edge of a thin plate; but a slit in a plate properly placed, allowing a line of light to pass, will evidently answer the purpose. Sometimes a small hole is preferred; and the hour lines, instead of being described on a plane surface, are sometimes described on the surface of a sphere, or a cylinder or a cone. The reader may find a description of some curious dials in Brewster's edition of Ferguson's *Lectures*. For the history of dialling, see Delambre, *Astronomie Ancienne*, tome ii.; Montucla, *Histoire des Mathématiques*, tome i.

Dialect (Gr. *διὰλεκτος*, from *διὰ*, and *λέγω*, I speak). In the philosophical sense of the word, any variety of a common language. Hence German, English, Swedish, &c. are all strictly said to be dialects, as coming all of them from the same original stock. Commonly, however, we limit the application of the term *dialect* to the varieties of a national language; and speak of the dialects of English, French, &c. In Greek the four dialects (Doric, Ionic, Æolic, Attic) were the four written varieties of the language, each possessing a literature of its own. In this respect no modern tongue presents a parallel to the Greek; inasmuch as, in all, one dialect has been arbitrarily adopted as

the standard of polite writing and conversation, and the written works which are extant : the other dialects are regarded merely as exceptions to the general rule.

Dialectics (Gr. *διαλεκτική*). This name was originally used by Plato as synonymous with *metaphysics*, or the highest philosophy. Strictly speaking, it can only be regarded as a preparatory discipline for such investigations, or at most as a scientific method of prosecuting them. The most splendid examples of dialectical subtilty that exist are to be found in the *Dialogues* of Plato, especially in those entitled *Parmenides*, the *Statesman* and *Sophist*. In a narrower sense, dialectics is defined as meaning that portion of logic which teaches the modes and rules of reasoning; and the logic of Aristotle undoubtedly owes its existence to the dialectical exercises of the Platonic schools; and may, in one point of view, be regarded as a body of canons and directions for their legitimate use. [PLATONIC PHILOSOPHY.] In modern times various systems of dialectics have been propounded in different countries; but by no philosophers, either ancient or modern, has this science been more successfully cultivated than by the Germans, who, among a host of other names more or less distinguished, can boast of a Fichte, Kant, Leibnitz, Hegel, Schelling, and Schlegel, as the propounders each of a peculiar dialectical system.

Diallage (Gr. *διαλλάσσω*, *I interchange*). A mineral of a foliated structure easily divisible in one direction, its natural joints and artificial fractures exhibiting a very different lustre and appearance.

Dialling Lines or Scales. Graduated lines, on rules or circles, to facilitate the construction of dials.

Dialogism (Gr. *διαλογισμός*). In Rhetoric, a mode of writing dialogue, in which the conversation of two or more persons is reported in the third person instead of the first. A speech by a single person, or a soliloquy, when reduced into the narrative form, is also, although somewhat incorrectly, termed by French literary writers *dialogism*.

Dialogue (Gr. *διάλογος*). In Literature, a composition or part of a composition in the form of a conversation between two or more persons. The dialogue was the form most generally adopted by the ancients for the conveyance of instruction, and was considered equally applicable to the most grave and philosophical, and to the most ludicrous and comical subjects. It was adopted by Plato, Cicero, and Lucian, with equal success. Among modern writers the philosophical dialogue has been frequently employed, more especially by the French. Among other eminent persons of that country who have enriched its literature with this species of composition are, Fénelon; Bouhours, in his *Entretiens d'Ariste et d'Eugène*; Fontenelle, in his *Dialogues of the Dead*, and *Plurality of Worlds*; Galiani, *Sur le Commerce des Grains*, &c. In England this method of composition has been less frequently

practised; and perhaps, with the exception of Berkeley and Hurd, has rarely succeeded in the hands of those who attempted it. Among the Italian writers of dialogue may be mentioned Machiavelli and Algarotti; and among the Germans, Lessing, Mendelssohn, Schelling, and Herder.

Dialuric Acid. A crystalline acid having the formula $C_6H_2O_7N_2 + HO$, obtained by the action of sulphuretted hydrogen on a boiling solution of alloxan.

Dialypetalous (a word coined from Gr. *διαλύω*, *to separate*, and *πέταλον*, *a leaf*). In Botany, a term equivalent to *polyptalous*, and applied to those plants which have distinct petals, in contradistinction to those which have the petals united into what is commonly called a *monopetalous corolla*, but which is more strictly said to be *gamopetalous*.

Dialysis (Gr. *διάλυσις*). A term applied by Mr. Graham to a process of analysis by diffusion through a septum. The apparatus used in the process is called a *dialyser*, and is constructed and employed in the following manner: The most convenient septum is the commercial article known as *parchment paper*, made by immersing unsized paper for a short time in sulphuric acid. A piece of this material is stretched over a gutta-percha hoop, and secured by a second external hoop. Such dialysers of useful size are one or two inches deep and five to ten inches wide. Liquids to be dialysed are poured into the dialyser, which is then floated in a flat dish containing distilled water.

The practical value of dialysis depends upon the fact that certain substances will diffuse through a given septum far more rapidly than others. Uncrystallisable bodies diffuse very slowly. Of such matters as starch, gum, albumen, and gelatin, the last-named is perhaps least diffusive; hence substances of this class are termed *colloids*, or bodies like *collin*, which is the soluble form of gelatin. Substances which diffuse rapidly are mostly crystalline; hence bodies of this class are termed *crystalloids*.

Aqueous solutions of two parts of the following named substances in 100 parts of water, were dialysed by Mr. Graham for twenty-four hours. The amounts of each substance which passed through the septum bore the following relations to one another:—

Chloride of sodium	. . .	1000
Ammonia	. . .	847
Theine	. . .	703
Salicine	. . .	603
Cane sugar	. . .	472
Amygdalin	. . .	311
Extract of logwood	. . .	168
Catechu	. . .	159
Extract of cochineal	. . .	51
Gallo-tannic acid	. . .	30
Extract of litmus	. . .	19
Purified caramel	. . .	5

The phenomena of dialysis show that crystalloids have a greater affinity for water than

DIALYTIC ELIMINATION

colloids have. If a solution of chloride of sodium be placed at the bottom of a jar, and covered by a hot solution of gelatine of sufficient strength to solidify on cooling, the chloride of sodium will diffuse up into the solid jelly, because the water of the solid jelly has a greater affinity for the salt than it has for the gelatine. The solid jelly may obviously be reduced in thickness, and water placed over it; indeed the conditions would then be still more favourable for diffusion. Replace the stratum of jelly by a permanent colloid, such as parchment paper; the result is the same, the permanent character of the septum admitting of its practical application.

Dialytic Elimination. A method, invented by Sylvester (*Philosophical Magazine*, vol. xxi. 1842), by means of which the resultant of two binary quantities may be expressed as a determinant. [ELIMINATION.]

Diamagnetic. A term applied to bodies which appear to be repelled by either pole of a magnet; as opposed to the term *magnetic* bodies, the particles of which are attracted by either pole.

Diameter (Gr. *διαμετρος*, from *διδ*, and *μετρος*, a measure). In Architecture, the measure across the lower part of the shaft of a column, which is usually divided into sixty minutes, and forms a scale for the measurement of all the parts of an order.

In Astronomy, the *apparent diameter* of a celestial body is the angle which the latter subtends at the eye, and is measured by the micrometer. The distance from the earth, of the body in question, when multiplied by the sine of this angle, gives the real diameter of the body.

DIAMETER. In elementary Geometry, any right line through the centre of a figure. In Conics, a diameter always bisects a system of parallel chords; a fact which appears to have led Newton to a more general definition of a diameter, applicable to curves of all orders. He showed that the *centres of mean distances* [CENTRE OF GRAVITY], upon a system of parallel lines, of the n intersections of each with a curve of any order always lie on a right line, which may be called a *diameter*. Now the centre of mean distances of a number of points in lines is nothing more than their *harmonic centre*, of the first order, with respect to an infinitely distant pole [HARMONIC CENTRES], so that Newton's theorem is merely a special case of Cotes' [POLES AND POLARS], and a diameter of any curve is simply the *polar line*, with respect to the curve, of an infinitely distant point. This leads naturally to a further extension of the term *diameter*, and to the recognition of $n - 1$ distinct *curvilinear diameters* of every curve of the n^{th} order; the r^{th} diameter being simply the r^{th} polar of an infinitely distant point, and consequently a curve of the $(n - r)^{\text{th}}$ order. The $(n - 2)^{\text{th}}$ diameter is called the *diametral conic*, the $(n - 3)^{\text{th}}$ the *diametral cubic* and so on. (Salmon's *Higher Plane Curves*.)

Precisely the same extension is applicable to

DIAMOND

surfaces. The diametral r -ic of a given surface of the n^{th} order is the $(n - r)^{\text{th}}$ polar, with respect to that surface, of an infinitely distant point. When the primitive surface is of the second order, there is, of course, but one diametral surface, and that is the *diametral plane* which bisects a system of parallel chords. It passes of course through the centre of the surface, and two diametral planes cut in a diameter. Three diametral planes, so situated with respect to each other that each bisects all chords parallel to the intersection of the other two, constitute a system of *conjugate diametral planes*, and intersect each other in *conjugate diameters*. In one such system the three planes, being perpendicular to each other, are called *principal diametral planes*; they intersect in the three *axes* or *principal diameters* of the surface.

Diametral Curves and Surfaces. [DIAMETER.]

Diametral Plane. [DIAMETER.]

Diamides. Neutral chemical substances derived from two atoms of ammonia by the replacement of successive thirds of the hydrogen by negative radicals.

Diamines. Artificial alkaloids derived from two atoms of ammonia by the replacement of successive thirds of the hydrogen by diatomic radicals like ethylene. [AMINES.]

Diamond (a corruption of *adamant*; Gr. *ἀδάμας*, *unconquerable*, from its extreme hardness and difficulty of fracture). This most valuable of precious stones, and the hardest of known substances, consists of pure or nearly pure carbon. The primary crystalline form of the diamond is a regular octahedron, of which there are many modifications; but it also often occurs in cubes and rhomboidal dodecahedrons, and sometimes in twin crystals; the faces are frequently convex. The most valuable diamonds are perfectly colourless and transparent; but those which are of decided tints of pink, green, or blue are much prized, while those which are only slightly coloured are held in least estimation. They are found in a detached state in alluvial deposits, from which they are extracted by washing. Diamonds were originally discovered in Bengal, and in the island of Borneo. The most celebrated mines of India were those of Golconda, and of Roalcondal in the Mahratta empire. In 1728 they were found in Brazil, and since that time the mines of Minas Geraes have produced most of the stones imported into Europe.

The art of cutting and polishing diamonds was discovered in 1466, by Louis van Berquen, a citizen of Bruges, who found that by rubbing two diamonds together their surfaces might be abraded. At the present time diamond-cutting is principally carried on by Jews at Amsterdam. They are cut chiefly into two forms, called *brilliant*, and *rose-diamonds* or *rosettes*, and sometimes into what are called, from their flat surface, *table-diamonds*. The brilliant form, which has from 56 to 64 facets, was first introduced by Cardinal Mazarin, in 1650. It is especially calculated to bring out the lustre and

DIAMOND

refractive powers of the gem. Thus a well-cut brilliant, held in a beam of light, reflects nearly the whole of the light which falls upon it, throwing it out and refracting it in coloured rays through the facets in front. With the exception of one small point of light through the *collet*, the brilliant forms an opaque shadow on a screen.

The largest known diamond is probably that mentioned by Tavernier as belonging to the Great Mogul. It was found in 1550 in Golconda; and in its original state is said to have weighed 900 carats. Among the crown jewels of Russia is a magnificent diamond, weighing 194 carats: it is of the size of a pigeon's egg, and was purloined from a Brahminical idol by a French soldier; it passed through several hands, and was ultimately bought by the Empress Catherine for the sum of 90,000*l.* and an annuity of 4,000*l.* One of the most perfect diamonds hitherto found, is a brilliant brought from India by a gentleman of the name of Pitt, who sold it to the regent duke of Orleans for 125,000*l.* It weighs 136½ carats (430·55 grains). Another very celebrated diamond is the Koh-i-noor (*the hill of lustre*), which became the property of her majesty on the annexation of the Panjab by the East India Company in 1850. It is mentioned by Tavernier, in 1665, as the property of the Mogul emperor, and together with the Doriainoor (*or the ocean of lustre*), another stone nearly as valuable, formed part of the plunder seized by Nadir Shah at the taking of Delhi in 1739. When brought to this country it weighed 186½ carats, but it has since been recut by the Messrs. Garrard, and although the weight of the stone has been reduced to 103¾ carats, its brilliancy and general appearance have been greatly improved.

The diamond was first proved to be combustible in 1794, by the Florentine Academicians, who found that, when exposed to the heat of the sun concentrated in the focus of a large lens, it burnt away with a blue lumbent flame. The *products* of its combustion were first examined by Lavoisier in 1772, who showed that when burnt in air or oxygen it produced carbonic acid. Subsequent experiments have demonstrated that nothing but carbonic acid is thus formed; and hence it is proved that the diamond is charcoal or carbon in a pure and crystalline form.

DIAMOND. In Printing, an exceedingly small type, five sizes smaller than that used in this work, and the smallest usually cast by the British type-founders. It was originally introduced for very small editions of the Bible. [TYPE.]

Diana. In Mythology, the name of a Latin goddess (the feminine form of Dianus or Janus), whom, however, the Latins soon identified with the Greek goddess Artemis. The latter, in the Hesiodic *Theogony*, is described as the daughter of Zeus and Leto (Latona), and the sister of Apollo or Hecatus, the far-shooter. She shares his attributes of destruction and healing, but not those of music

DIAPHANOUS

and prophecy. She is also one of the three goddesses who are described as ever virgin; the other two being Athena (Minerva) and Hestia (Vesta). (Homer, *Hymn to Aphrodite*, 8-24.) She is in fact the growth of that subdivision of attributes, which out of the Indra or Sun, of Sanscrit mythology, evolved the several persons of Apollo, Artemis, Helios, Hyperion, Phaethon, &c. The Ephesian Artemis, whose worship throughout the Asian district is spoken of in the Acts of the Apostles, seems to be an entirely different goddess, whose chief work was that of natural reproduction. The well-known temple of this goddess at Ephesus was set on fire by Eratostatus on the day on which Alexander the Great was born. It was rebuilt, but destroyed again A.D. 260.

Diana, Tree of. A name given by the old chemists to the crystallised silver which is separated when mercury is put into a solution of nitrate of silver.

Diandrous (Gr. *dis*, and *andros*, a man). In Botany, a term applied to any plant having but two stamens.

Dianic Acid. This term has been applied to the oxide of a metal said to be allied to Niobium.

Diapason (Gr. *through all*). In Music, an interval used by most authors to express the octave of the Greeks. For an account of the diapason in the organ pipes, see ORGAN.

By the French this term is used as an equivalent to our word *pitch*; and also to denote a pipe, fork, or other instrument by which the pitch is determined.

Diapensiaceæ (Diapensia; one of the genera). A group of corollifloral Exogens of the Gentianial alliance, consisting of prostrate undershrubs, found in the northern parts of Europe and North America. Their peculiar features are the absence of stipules, interpetalous stamens, simple stigmas at the end of a manifest style, axile placenta, and indefinite seeds.

Diapente (Gr. from *dis*, and *πέντε*, five). In Music, an ancient term signifying a fifth.

Diaper (Fr. *diapré*). A woven linen ornamented with patterns, and used for towels and table linen; it sometimes resembles an inferior kind of damask. It is said to have been originally manufactured at Ypres in Flanders, and hence to have received its name.

DIAPER. A term used to signify the repetition of a pattern of any flowers, foliage, or geometrical form of ornamentation, over a large surface of work; it differs from *chequers* inasmuch as the latter is applied to a repetition of geometrical figures which are indicated by rectangular or diagonal lines intersecting one another at fixed intervals.

Diaphanous (Gr. *διαφανής*, transparent). A term applied to bodies which, like porcelain, permit the light to pass through their substances. It is the synonym of *translucent*. A body which allows the distinct forms of objects to be seen through it is *transparent*.

DIAPHONICS

Diaphonics (Gr. *διδ*, and *φωνή*, sound). The doctrine of refracted sound. [SOUND.]

Diaphoresis (Gr.). A perspiration: hence also *diaphoretics*, medicines which promote perspiration.

Diaphoretic Antimony. In old Pharmacy, a term applied to the peroxide of antimony, and also to the antimoniate of potassa.

Diaphragm (Gr. *διάφραγμα*, literally a partition). In Conchology, this term is applied to the straight calcareous plate which divides the cavity of certain shells into two parts. In Anatomy, its common signification relates to the muscular and tendinous partition which separates the chest from the abdomen in mammalia. This term is also applied to the stop in a photographic camera, and to the perforated circular plates used in telescope and microscope tubes to allow only the light from the object-glass to reach the eye-piece.

Diaphragm Shell. [SHRAPNEL SHELL.]

Diapophysis (from Gr. *ἀνάρσις*, an offshoot or process). In Anatomy, the upper of the two transverse processes which project from the sides of the cervical and anterior dorsal vertebrae of the crocodile, and which is usually ankylosed with a rudimental rib in the cervical vertebrae of birds and mammals; in these it forms the sole 'transverse process' of the succeeding vertebrae, and is usually developed from the neural arch.

Diarrhoea (Gr. *διάρροια*, a flowing through). A purging or looseness of the bowels. There are several varieties of diarrhoea, depending upon different causes, and consequently requiring in many instances distinct modes of treatment. In general it is necessary first to remove offending and irritating matters from the bowels by means of aperients; rhubarb, from its astringent tendency, is the purgative usually employed; afterwards astringents with warm aromatics, and the occasional addition of some form of opium, are prescribed and continued till the inordinate laxity of the bowels is quelled. Where diarrhoea is connected, as it often is, with excess of acidity in the stomach, magnesia, chalk, or carbonated alkalies are united to the other remedies.

Diarthrosis (Gr. *articulation*). The movable connection of bones.

Diary (Lat. *diarium*, literally a daily allowance). This term signifies properly a note-book or register of daily occurrences, in which the writer has a principal share, or which have come under his own observation, or have happened in his own time. The term *diary* is equivalent to the French *journal*, the Italian *diario* and *giornale*, and the German *Tagebuch*.

Diastichisma (Gr. *διαστίχμα*, I cleave). In Music, an interval consisting of two commas.

Diaspore (Gr. *διασπορά*, to scatter). A mineral which is usually found in thin flattened prisms (sometimes acicular) or in slightly curved laminae. It is a hydrate of alumina. Small pieces decrepitate and are dispersed in numerous fragments, when heated in the flame

DIATONIC

of a candle or before the blowpipe; hence its name.

Diastase (Gr. *διδ*, and *ιστημι*, I place). A white amorphous substance generated during the germination of barley, wheat, &c. which tends to accelerate the formation of sugar during the fermentation of worts. It is precipitated from infusions of bruised malt by alcohol. It is the principle which by its reaction on starch tends to its conversion into dextrine and glucose, one part of it being sufficient for the conversion of 2,000 parts of starch.

Diastem (Gr. *διαστήμα*). In Ancient Music, a simple interval as distinguished from a compound one; to which latter was given the name of a *system*.

Diastema (Gr.). In Zoology, the vacant space occurring in the dental series by the absence of the canine or laniary teeth.

Diastole (Gr. from *διδ*, and *στέλλω*, I place). The dilatation of the heart and arteries.

Diastyle (Gr. *διαστυλος*). In Architecture, that mode of arranging columns in which the space between two consecutive columns consists of three diameters, or, according to some, of four diameters.

Diatesaron (Gr. from *διδ*, and *τέσσαρες*, four). In Ancient Music, the interval of a fourth.

DIATESARON. In Ecclesiastical History, this name is given to Harmonies of the Gospels, of which the earliest was that of Tatian, in the second century. This work has long been lost.

Diathermal or Diathermanous (Gr. *διδ*, and *θερμν*, warmth). A term applied to certain substances, such as transparent pieces of rock-salt, &c., which suffer radiant heat to pass through them, much in the same way as transparent or *diaphanous* bodies allow of the passage of light.

Diathesis (Gr. *a disposition*). A particular state of constitution predisposing to certain diseases: such as inflammatory, nervous, and putrid diathesis; uric diathesis, in which there is excess of uric acid thrown off by the kidneys; gouty diathesis, &c.

Diatomaceæ (Diatoms, one of the genera). A group of *Algae*, of low organisation, closely related to *Desmidiaceæ*, but remarkable for the enormous quantity of siliceous which they contain. Vast beds occur, many feet in thickness, consisting entirely of effete frustules, as the separate joints of the fronds are called. These beds are known by the name of *Tripoli*, and afford an admirable article for polishing. They occur again in the form of white powder, known as *Mountain Meal*, which is mixed with flour in some parts of Sweden. The *Diatomaceæ* form a large portion of the food of some of the lower molluscs. They occur in all parts of the world, enduring extreme degrees of cold without annihilation, and are found also in springs of high temperature. For further information, see Smith's *Diatomaceæ*, and the Rev. M. J. Berkeley's *Cryptogamic Botany*.

Diatonic (Gr. *διατονικός*, from *διδ*, and *τόνος*, a tone). In Music, a term denoting the

DIATONIC SCALE OF COLOURS

natural scale of music, which, proceeding by degrees, includes both tones and semitones.

Diatonic Scale of Colours. Newton found, or supposed, that the spaces occupied by the seven primary colours in the solar spectrum are exactly proportional to the length of strings that sound the seven notes in the diatonic scale of music. It is now known, however, that the relative lengths of the spaces occupied by the different colours in the spectrum depend on the nature of the substance of which the refracting prism is formed. [CHROMATICS.]

Dibble. In Agriculture and Horticulture, a cylindrical piece of wood from one to two inches in diameter, and from 1 ft. to 2 ft. in length, having a cross or loop handle at one end, and brought to a conical point at the other, for the purpose of making holes in the ground to receive plants or seeds. Dibbles which are used for planting potatoes or beans are commonly from two to two and a half feet in length, with a peg inserted near the ground in order that the operator may press it with his foot.

Dibothrians, Dibothri (Gr. *δῖς*, and *βόθρος*, a pit). The name of a division of tape-worms, including those *Bothriocephali* which have not more than two pits or fossæ on the head.

Dibranchiates, Dibranchiata (Gr. *δῖς*, and *βράγχια*, gills; two-gilled). The name of the order of Cephalopods which includes those with two gills, and which are also characterised by having three distinct hearts; an apparatus for secreting and emitting an inky fluid; cephalic arms, never exceeding ten in number, solid, and supporting acetabula; and in short all the chief characteristics which are usually ascribed to the entire class of Cephalopods. The same term (*Dibranches*) is applied by Latreille to an order of the class *Cirripedia*, comprehending those species which are similarly characterised by having two gills.

Dicast (Gr. *δικαστής*, from *δικη*, justice). A certain number of Athenian citizens, chosen annually by lot to represent the whole body of the people, while performing certain judicial functions, were called *dicasts*. In their being so selected, and in their oath that they would rightly discharge the duties of their office, they bore some resemblance to our jurors; but here the likeness ceased. The dicasts received pay; and none could be elected under thirty years of age, and unless they possessed the full franchise. The number of persons chosen annually for this office was 5,000. The whole body of dicasts was termed *dicasterion*, and the same name was applied to the place in which they sat.

Dice Coal. A species of coal easily splitting into cubical fragments.

Dicerates, Dicerata (Gr. *δῖς*, double, and *κέρας*, horn; two-horned). A name applied by De Blainville to a family of the order *Paracéphalophora Polybranchiata*, comprehending all such Gastropodous Molluscs as have two tentacles on the head. The term *Diceras* was

DICLINOUS

previously applied by Lamarck to a fossil genus of Bivalves.

Dichlamydeous (Gr. *δῖς*, and *χλαμός*, a garment). In Botany, a term applied to plants having both calyx and corolla.

Dichloraniline. Aniline, in which two equivalents of hydrogen are replaced by chlorine.

Dichobune (Gr. *δίχα*, apart, and *βουνός*, hill). A genus of even-toed (artiodactyle) mammalia which has been discovered in the Upper Eocene beds of Hampshire. It is closely allied to *Anoplotherium* and *Xiphodon*; unlike those genera, there is, however, a slight interval between the canine and the first premolar in both jaws.

Dichodon (Gr. *δίχα*, and *δούς*, tooth). In this genus, allied to *Anoplotherium* and *Dichobune*, the dental series is continuous without break—a character which amongst existing mammals is manifested by mankind alone; the crowns of the teeth in *Dichodon* being all of nearly equal height, as they are in man. The *Dichodon cuspidatus* was as large as a fallow-deer.

Dicholophus (Gr. *δίχα*, and *λόφος*, a crest). The name of the genus of wading birds (*Grallatores*), including the *Cariamia*, which is characterised by a tuft of feathers projecting from the crown of the head in two directions.

Dichotomous, Dichotomus (Gr. *διχότομος*). Signifies the division of an object by repeated bifurcation, so that the branches are always in pairs.

Dichotomy (Gr. *διχότομία*). An artificial system for the arrangement of natural objects based upon principles of binary distinction.

In Logic, the division of a class into two sub-classes which are opposed to each other by contradiction. The reduction can be made at each stage of any division, however complex.

Dichroism (Gr. *δῖς*, twofold, and *χρῶς*, colour). In Mineralogy, this term is applied to those minerals which present different colours, when viewed by transmitted light, in two different directions; the colours being the same in the direction of like axes, and different in that of unlike axes. Iolite is an example of this property, and the name *Dichroite* has been given to it in consequence. Mica affords another instance, being nearly opaque when viewed in one direction, but transparent and of a different colour in another. A good instance of dichroism occurs in the crystals of chloride of palladium, which appear of a deep red colour along the axis, and of a vivid green when viewed in a transverse direction.

Dichroite (Gr. *δῖς*, and *χρῶς*, colour). A mineralogical synonym for Iolite, in allusion to its dichroism, or display of different colours when viewed by transmitted light in different directions. [DICHROISM.]

Diclinalous (Gr. *δῖς*, and *κλίση*, a bed). In Botany, having the stamens and pistil separated, that is to say, situated in separate flowers, sometimes on the same plants, sometimes on distinct plants.

Dicompounds. The prefix *di* to a chemical compound generally implies that it contains two atoms of base, or electro-positive element, to one of salifying or electro-negative element. Dicarbonate of copper, for instance, is a compound of two atoms of oxide of copper with one atom of carbonic acid; dichloride of mercury, a compound of two atoms of mercury and one of chlorine, &c.

Dicotyledons (Gr. *δῖς*, and *κοτυληδών*). One of the primary classes of the vegetable world, consisting of all those plants that have their embryo furnished with two cotyledons, or with a greater number arranged on the same plane. These plants are also called *Exogens*.

Dictator (Lat.). In Roman History, an extraordinary magistrate, invested with absolute power for the period of six months. The office seems to have existed in many Latin towns before it was introduced into Rome. Of the reasons for its introduction into the latter state we have very inconsistent accounts. According to some, T. Lartius was the first dictator; according to others, M. Valerius. Livy ascribes the appointment to the exigencies of a Latin war; Dionysius affirms that it was owing to the discontent of the plebeians, who refused, until relieved of their debts, to serve in the army. Niebuhr's idea that the Roman dictator, as holding office for six months, was head of a Roman and Latin confederation, while a Latin dictator had supreme power for the rest of the year, is mere theory. Dictators were appointed not only when the state was in danger, but sometimes for ceremonial purposes, as for holding the comitia, fixing the *clavus annalis*, &c. They could not legally hold office for more than six months; but they usually resigned it in a few days or weeks. It is very doubtful whether election by the curia was necessary to the appointment; but the nomination by the consul was indispensable. The office was at first confined to the patricians; but, like the rest, was in course of time opened to the plebeians, the first plebeian dictator, C. Marcus Rutilius, being appointed a.c. 356. So far as we know, it was not subject to the Valerian law of appeal; but the tribunes of the people continued to discharge their functions during a dictatorship, although all other offices were suspended. The dictator had the appointment of the *magister equitum*, or master of the horse, who in his absence exercised dictatorial power. The dictatorships of Sulla and Cæsar were altogether irregular and illegal, and were, in fact, dictatorships only in name.

Dictionary (Mod. Lat. *diccionarium*). A collection of words in one or more languages, with their peculiar significations, arranged in alphabetical order; but the term may be applied in a more extended sense to any work which professes to give information on an entire subject, or an entire branch of a subject, under words or heads digested in order of the alphabet. Hence dictionaries may be said to be of two sorts - of words, and of facts or things; in the

former sense the term *dictionary* being equivalent to *lexicon*, in the latter to *encyclopædia*.

Dictionaries of Words.—No dictionaries belonging to a time before the Christian era have come down to us; and the attempts made to supply the want of such books in the early centuries of Christianity and during the middle ages, were comparatively incomplete. The Greek lexicographer, Suidas, is supposed to have lived in the eleventh century. His lexicon, printed at Milan in 1499, has been of the greatest service to succeeding scholars. It was republished in 1834, in an amended form, by the late Dr. Gaisford, Regius Professor of Greek at Oxford. A great advance was made in 1535 by the publication of the Latin Thesaurus of Robert Stephens (Étienne); and the Greek Thesaurus of his son, Henry Stephen, has furnished the groundwork for all later Greek dictionaries. The honour of possessing the best dictionaries of modern languages belongs to Italy, France, and England. These are the *Vocabulario degli Accademici della Crusca*, extended in the latest editions to 6 vols. fol.; the *Dictionnaire de l'Académie Française*, 2 vols. 4to., to which a supplementary volume has been recently added; Johnson's *Dictionary*, 2 vols. fol., 1755; to which must be added the Dictionaries of Dr. Richardson and Dr. Webster. The Spaniards also possess a dictionary of considerable reputation, entitled *Diccionario de la Lengua Castellana, compuesto por la Real Academia Española*, 6 vols. fol. 1726.

Dictionaries of Facts or Things are of two species; being either devoted to separate or single branches of science, art, or literature, or embracing the whole circle of the arts and sciences. Of the former, the *Historical and Critical Dictionary* of Bayle, and the *Dictionnaire de la Bible*, by Dom Calmet, may serve as specimens; and of the latter, the *Encyclopédie Française* and the *Encyclopædia Britannica*. That the idea of comprising all the sciences in a single work was not unknown in antiquity, may perhaps be inferred from the expression *ἑνὸς λόγου παιδεία*, which was used to signify such a course of instruction as should embrace all the sciences. The earliest approximation to this species of literature is to be found in the work of Varro, *Resum Humanarum et Divinarum Antiquitates*, of which nothing remains but the title; and in the *Historia Naturalis* of Pliny, who has embodied in that work all the results of his multifarious studies and vast erudition. But the term *Encyclopædia* is said to have been first applied to works of this description by some of the Arabian writers of the middle ages, and particularly by Alfarabius, whose general treatise on the sciences is still preserved under this designation. Towards the close of the sixteenth and commencement of the seventeenth centuries, there appeared in Europe several similar treatises with the same title, of which the most celebrated was that of Alstedius, in 2 vols. fol.; but none of these productions can properly be termed dictionaries

DICTIONARY

or encyclopædias, being merely collections of treatises resembling rather such works as Kettl's *Elements of General Knowledge*, &c., than corresponding to the modern notion of an encyclopædia. The strongest resemblance to the works in question is presented by the *Lexicon Universale Historicum Sacrum et Profanum* of Hofmann, 1677, in 2 vols. fol., and followed in 1683 by a supplement of equal extent; the form of which, at least, has served for a model to nearly all succeeding dictionaries or encyclopædias. It might perhaps be preposterous to assert that Hofmann borrowed the notion of his *Lexicon* from Bacon's theory of the *Encyclopædian Tree*, as set forth in the *Novum Organon*; but, as M. Guizot has observed, there can be little doubt that the great abundance of dictionaries and encyclopædias which the whole of Europe has since witnessed is in some degree owing to that eminent philosopher's classification of human knowledge.

The subjoined list contains a selection of the most valuable productions in this department of literature which have appeared since that time, arranged according to the place and date of their publication.

Great Britain.

1. *Lexicon Technicum*, or Universal Dictionary of the Arts and Sciences, 2 vols. fol.; the first published 1704, the second in 1710. A supplementary vol. was afterwards added.
2. *Chambers's Cyclopædia*, 2 vols. fol. 1728. This work was extended in a 7th edit. to 4 vols. fol. 1778-86, by Dr. Rees, who afterwards re-edited the work in 45 vols. 4to. (See *infra*.)
3. *An Universal History of Arts and Sciences*, &c., by Dr. De Coetlogon, 2 vols. fol. 1746.
4. *Barrow's New and Universal Dictionary of Arts and Sciences*, 1 vol. fol. 1761; with a supplementary vol. 1764.
5. *A New and Complete Dictionary of Arts and Sciences*, by a Society of Gentlemen (commonly called Owen's Dictionary, from the name of the publisher), 4 vols. 8vo. 1764.
6. *The Complete Dictionary of Arts and Sciences*, 3 vols. fol. 1766, by the Rev. Ben. Croker, Dr. Thos. Williams, and Sam. Clark.
7. *Encyclopædia Britannica*, 3 vols. 4to. 1771. The fifth edition of this work, completed in 1814, was extended to 20 vols.; and a supplement in 6 vols., under the editorship of Mr. Napier, added in 1824. A seventh edition of this work was completed in 1840, under the care of the same editor. The eighth edition, with large additions and improvements, appeared in 1860.
8. *The English Encyclopædia*, 10 vols. 4to. 1796-1803.
9. *The Cyclopædia*, commonly known by the name of *Rees' Cyclopædia*, 1802-19. 45 vols. 4to.
10. *British Encyclopædia*, 6 vols. 8vo. 1807-9.

11. *Encyclopædia Londinensis*, 24 vols. 4to. 1810-29, by John Wilkes.
12. *Brewster's Edinburgh Encyclopædia*, 18 vols. 4to. 1810-30.
13. *Pantologia*, or *New Dictionary of Arts and Sciences*, 12 vols. 8vo. 1813-16. By Mason Good, Gregory, and Bosworth.
14. *Burrow's Modern Encyclopædia*, 10 vols. 4to. 1816.
15. *Encyclopædia Edinensis*, 6 vols. 4to. 1816.
16. *Encyclopædia Perthenais*, 23 vols. roy. 8vo.; completed in 1816.
17. *Encyclopædia Metropolitana*, 1818.
18. *Oxford Encyclopædia*, 6 vols. 4to. 1824; supplement in 1 vol. 1831.
19. *The London Encyclopædia*, 24 vols. 8vo. 1826.
20. *Partington's British Cyclopædia*, 10 vols. 8vo. 1833-36.
21. *Penny Cyclopædia*, large 8vo. 1833-1843, 27 vols., and suppl. 2 vols.
22. *Knight's English Encyclopædia*, 22 vols. imp. 8vo. 1853-61.
23. *Chambers's Encyclopædia* (in course of publication).

France.

1. *Dictionnaire Universel Français et Latin*, known by the name *Dictionnaire de Trévoux*, 1704. 3 vols. fol. The fifth and last edition, Paris, 1771, 8 vols. fol.
2. *Encyclopédie, ou Dictionnaire raisonné des Sciences, des Arts, et des Métiers*, par Diderot et d'Alembert, 35 vols. fol. 1751-80. The original series 28 vols., 11 plates. A suppl. of 5 vols. was afterwards added, one of which consisted of plates; and a 'Table Analytique' 2 vols.
3. *Encyclopédie, ou Dictionnaire Universel raisonné des Connaissances Humaines*, par le Professeur de Felici. Yverdun, 1770-75. 42 vols. 4to.; and suppl. 6 vols. 4to.
4. *Encyclopédie Méthodique*, &c., 1782-1832, 201 vols. 4to., including 47 vols. of plates.
5. *Dictionnaire des Sciences et des Arts*, par Lumier, 3 vols. 8vo. 1805.
6. *Encyclopédie Moderne*, &c., par M. Courtin, 1823, &c. 24 vols. 8vo.
7. *Encyclopédie des Dames*, par une Société des Dames, Paris, 1821, &c.
8. *Dictionnaire de la Conversation et de la Lecture*. Paris, 1834-9, 52 vols. 8vo. or 104 livraisons.
9. *Encyclopédie des Gens du Monde*. Paris, 1833, &c. 22 vols. 8vo., completed in 1845.
10. *Dictionnaire Général des Sciences théoriques et appliquées* par Privat-Deschanel et Ad. Focillon; Paris, Masson et Fils (in course of publication).

Germany.

1. *Grosse, vollständige Universal Lexicon*, von Zedler, 1732-50, 64 vols. 8vo.; with a suppl. Another edition was published 1761-64 in 4 vols. fol. Halle and Leipzig.
2. *Deutsche Encyclopædie*, &c., 1778-1804, by Koester and Roos. Of this work 23 vols. 4to. appeared, bringing it down to letter K.

DICTIONARY

3. *Economische Encyclopedie*, by Krunitz, Floerke, and Korte, 1774-1828. 148 vols. 8vo. Berlin.
4. *Conversations-Lexicon*, 1796-1809, 6 vols. 8vo.; besides a supplement of 2 vols. The 6th edition was completed at Leipzig, 1824, in 10 vols., with 2 of a supplement; since that time there have appeared several editions of this work, materially augmented. An English translation of it was completed at Philadelphia, in 13 vols. 8vo. 1820-33; republished at Glasgow in 6 vols.
5. *Allgemeine Encyclopedie der Wissenschaften und Künste*, von Ersch und Gruber, 1818, &c. Leipzig.
6. *Gehler's Physicalisches Wörterbuch*, neu bearbeitet von Brandes, Gmelin, Horner, Muncke, Pfaff, 9 vols. 8vo. Leipzig, 1825-40.
7. *Haus-Lexicon, or Vollständiges Handbuch praktischer Lebens-kentnisse für alle Stände*, 8 vols. 8vo. Leipzig, 1835-37.
8. *Damen Conversations-Lexicon*, 10 vols. small 8vo. Adorf, 1835-38.

Besides these, no fewer than twenty Encyclopedias of greater or less extent have been published in Germany; but, with the exception of the *Conversations-Lexicon der Gegenwart*, which forms a species of supplement to the *Conversations-Lexicon* above specified, they are not of such general importance as to be noticed here.

Italy.

1. *Dizionario Scientifico e Curioso, Sacro, Profano*, by G. P. Pinati. 10 vols. fol. Venice, 1746-51.
2. *Encyclopedia Italiana*. Naples, 1788.
3. *Encyclopedia Methodica, Critica, Ragionata delle belle Arti*, by Pietro Zani Parma, 1818-20.

America.

1. *Encyclopedia Americana*. A popular Dictionary of Arts, Sciences, Literature, History, Politics, and Biography. A new edition, including a copious collection of original articles in American biography, on the basis of the seventh edition of the German *Conversations-Lexicon*, edited by Francis Lieber, assisted by E. Wrigglesworth. 14 vols. 8vo. cloth, edited by Henry Vethake, LL.D., Philadelphia, 1829-31. Vol. xiv., Philadelphia, 1846.
2. *The New American Cyclopaedia*. Edited by George Ripley and Charles A. Dana. (Vol. I. A—Araguays, royal 8vo. pp. 752 & xxvi. New York, 1858.)

But another branch of the same encyclopaedian tree, which yielded such brilliant fruits in the hands of Ducange, Bayle, and Calmet, has taken deep root in Europe, and more especially in this country, and has greatly contributed to the diffusion of knowledge; viz. the compilation of Dictionaries appropriated to separate branches of literature, science or art. The grand object aimed at in such works, is to place within the reach of persons engaged in the

DIDELPHYS

business of active life a mass of well-digested, accurate, and readily accessible information upon subjects not connected with their own immediate pursuits, such as it might be exceedingly difficult for them to procure elsewhere; while even to the learned, or to those who have access and leisure to refer to more extensive depositories of human knowledge, they serve as convenient manuals or reference books.

Dictum (Lat. *something said*). A word used in common parlance to signify the arbitrament or award of a judge.

Dietyogens (Gr. *διδυος*, a net). A name proposed by Lindley for a subclass of plants previously associated with Endogens, distinguished by having net-veined instead of parallel-veined leaves. The class includes the *Dioscoreaceae*, *Smilacaceae*, *Trilliaceae*, *Roxburghiaceae*, and *Philesiaceae*.

Dietyophyllum (Gr. *διδυος*). A name given by Lindley and Hutton to a fossil leaf from the upper sandstone, shale, and coal of the Yorkshire oolite, and employed to designate all fossil leaves of a common reticulated structure; the term *phyllite* being applied to leaves whose principal veins converge both at the base and apex.

Didactic (Gr. *διδακτικός*, from *διδάσκω*, I teach). In the schools, this term signifies every species of writing, whether in verse or prose, the object of which is to teach or explain the rules or principles of any art or science. Thus, to this class of literature belong the writings of Aristotle on grammar, poetry, and rhetoric; Longinus's *Treatise on the Sublime*; the *Institutiones* of Quintilian, &c. But the term is more exclusively applied to all poetical writings devoted to the communication of instruction on a particular subject, or of a reflective or ethical character, thence called *didactic poetry*. Among the most celebrated poems of this species may be reckoned in ancient times that of Lucretius, *De Rerum Natura*, in which the Epicurean system of philosophy is explained; Virgil's *Georgics*; and Horace's *Art of Poetry*; in more recent times, Pope's *Essay on Criticism* and *Essay on Man*; Du Fresnoy's *Art of Painting* (see Mason's translation, in the *Literary Works* of Sir J. Reynolds); Vida and Boileau's *Art of Poetry*; Akenside's *Pleasures of the Imagination*; Armstrong's *Art of Preserving Health*; Somerville's *Chace*; Dyer's *Fleece*; Young's *Universal Passion*, &c.

Didactyle (Gr. *διδάκτυλος*, two-fingered). This epithet is applied to various animals, as to the ruminants among quadrupeds (by Klein); to the ostrich among birds; to the amphiuma, an amphibious reptile with two digits on each extremity; and to certain insects, as the *Pterophorus didactylus* and *Gryllotalpa didactyla*.

Didelphys (Gr. *δίδυς*, and *δελφός*, womb). A generic name originally applied to the opossum, and all other quadrupeds which like it have a duplicature of the integument of the abdomen forming a pouch, in which the young are received, protected, and nourished, as in a womb, until their growth is advanced

DIDUS

to a stage corresponding to that of the new-born young in the ordinary mammalia. In modern systems the term is, singularly enough, restricted to that group of Marsupials in which there are certain species deficient in the abdominal pouch. The genus *Didelphys*, or true opossums, are characterised by the following dental formula: incisores $\frac{10}{8}$, canini $\frac{2}{2}$, mo-

lares spurii $\frac{6}{8}$, molares veri $\frac{8}{8}$, = 50; and by

having the hinder foot provided with a thumb, and a prehensile tail.

Didus. The generic name for the dodo or dronte. Birds of this kind were discovered by the Portuguese in 1499 on the island now called Mauritius, where they were afterwards observed by the Dutch in 1598, and in the early part of the following century. Original figures of the bird are given in *De Bry* (*Quinta pars India Orientalis*, &c. 1601); by Clusius, in his *Exotica*, 1605; by Herbert, in his *Travels*, 1634; by Bontius (Piso's edition, 1658); and by Savery, in his celebrated picture of 'Orpheus charming the Beasts,' now in the museum at the Hague. The last figure is the best; it was painted, as were the other figures of exotic species in the same picture, from studies of the living animals preserved at that time in the menagerie of Prince Maurice of Nassau. It is highly probable that the same dodo was the subject of the painting of which the one now in the British Museum is a copy.

Besides this pictorial evidence there exist a head and a foot of the dodo in the Ashmolean Museum at Oxford, and a foot of the dodo in the British Museum. The following is Willoughby's translation of the original description of this extinct bird by Clusius: 'The dodo is called by Clusius, *Gallus gallinaceus peregrinus*; by Nie-remberg, *Cygnus cucullatus*; by Bontius, *Dronte*. This exotic bird, found by the Hollanders in the island called by the Portuguese *Cygnæa* or *Cerna*, that is the Swan Island, and Mauritius Island by the Low Dutch, of thirty miles' compass, famous especially for black ebony, did not exceed a swan in bigness; but was of a far different shape, for its head was great, covered as it were with a certain membrane resembling a hood; besides, its bill was not flat and broad, but thick and long, of a yellowish colour next the head, the point being black. The upper chap was hooked; the nether had a bluish spot in the middle, between the yellow and black part. They reported that it is covered with thin and short feathers, and wants wings, instead whereof it hath only four or five long black feathers; that the hinder part of the body is very fat and fleshy, wherein for the tail were four or five small curled feathers, twirled up together, of an ash colour. Its legs are thick rather than long, whose upper part, as far as the knee, is covered with black feathers; the lower part, together with the feet, of a yellowish colour; its feet divided into four toes, three (and those the longer) standing forward, the

fourth and shortest backward, all furnished with black claws. After I had composed and writ down the history of this bird, with as much diligence and faithfulness as I could, I happened to see in the house of Peter Pauwius, primary professor of physic in the university of Leyden, a leg thereof cut off at the knee, lately brought over out of Mauritius his island. It was not very long from the knee to the bending of the foot, being but little more than four inches, but of a great thickness; so that it was almost four inches in compass, and covered with thick-set scales; on the upper side broader, and of a yellowish colour; on the under (or back side of the leg) lesser and dusky. The upper side of the toes was also covered with broad scales; the under side wholly callous. The toes were short for so thick a leg; for the length of the greatest or middlemost toe to the nail did not much exceed two inches; that of the other toe next to it, scarce came up to two inches; the back toe fell something short of an inch and a half; but the claws of all were thick, hard, black, less than an inch long; but that of the back toe longer than the rest, exceeding an inch. The mariners in their dialect gave this bird the name *Walgh-vogel*, that is, a nauseous or yellow bird; partly because after long boiling the flesh became not tender, but continued hard, and of difficult concoction excepting the breast and gizzard, which they found to be of no bad relish, partly because they could get many turtle-doves, which were much more delicate and pleasant to the palate. Wherefore it was no wonder that in comparison of those they despised this, and said they could be well content without it. Moreover they said that they found certain stones in its gizzard; and no wonder, for all other birds, as well as these, swallow stones to assist them in grinding their meat.' Thus far Clusius.

Now with respect to the parts of the bird which still remain to us, we infer that the head from the sudden rising of the cranium above the face, and the form of the anterior extremity of the lower jaw, as also from the nostrils being covered with an arched scale) did not belong to vulture or any other Accipitrine bird; while in the presence of the cere at the base, and the forward position of the nostrils, it resembles the rhea and apteryx among the Struthious birds. The apteryx, however, deviates more from the typical *Struthionida* in the shape of the bill and position of the nostrils than does the dodo. With respect to the foot in the British Museum, this differs from that of the vultures in the form and disposition of the tarsal scales, in the shortness of the middle toe, and the bluntness and straight figure of the claws; while in all these respects it agrees with the foot of the apteryx and the Gallinaceous order. Hence, even those naturalists who still reject the evidence in proof of the Struthious nature of the dodo, and deny its existence at any period, are compelled to imagine that the bird represented in the original figures above quoted was made up by joining the head of a bird of prey

DIDYMIUM

to the legs of a Gullinaceous bird. The analogies of ornithology, however, by no means sanction the rejection of the multiplied, and, if we accept Leguat's narrations, consistent, evidence of the actual existence of the Struthious dodo. Whoever inspects the painting by Savery, above mentioned (which seems hitherto to have escaped the attention of the naturalists who have written on the dodo), must feel a conviction that its original was no factitious or artificial specimen. Neither the head nor the feet still preserved in our museums can be referred to an albatross, a penguin, a vulture, or any other known existing species; while they closely correspond (allowing for the absence of the horny sheath of the bill) with the original figures of the dodo. We have therefore no hesitation in concluding that in other respects those figures are equally faithful representations of the extinct Struthious form in question. Such also appears to be the conclusion to which the learned writer of the article 'Dodo' in the *Penny Cyclopædia* arrived: 'If the picture in the British Museum and the cut in Bontius be faithful representations of the creature then living, to make such a bird a bird of prey, a vulture in the ordinary acceptation of the term, would be to set all the usual laws of adaptation at defiance. A vulture without wings! How was it to be fed? And not only without wings, but necessarily slow and heavy in progression on its clumsy feet. The *Vulturida* are, as we know, among the most active agents in removing the rapidly decomposing animal remains in tropical and intertropical climates; and they are provided with a prodigal development of wing to waft them speedily to the spot tainted by the corrupt encumbrance. But no such powers of wing would be required by a bird appointed to clear away the decaying and decomposing masses of luxuriant tropical vegetation—a kind of vulture, for vegetable impurities, so to speak; and such an office would not be by any means inconsistent with comparative slowness of pedestrian motion.'

Mr. Hugh Strickland, in his work *The Dodo and its Kindred*, advocated the theory that this bird belonged to the group *Columbidae*, and that it was, in fact, a gigantic pigeon, allied to the *Didunculus* which is found in the Samoan Islands in the Pacific Ocean. Dr. Melvill supported this conclusion by the comparison of the osteological evidences preserved to us with those of existing *Columbidae*. In 1851, Mr. Bartlett, the taxidermist, prepared an ideal model of the dodo, based on the pictorial evidences, which was exhibited at the International Exhibition. The strenuous exertions of future travellers near the Mauritius may, by the discovery of osteological proofs, afford a more conclusive demonstration of this remarkable extinct bird.

Didymium (Gr. *δίδυμος*, twin). A metallic element associated with cerium in the mineral cerite. Its salts are mostly of a red colour; but didymium is scarcely known in the metallic state.

DIESPITER

Didymous. In Botany, growing in pairs, like the fruit of Umbelliferous plants.

Didynamous (Gr. *δύς*, and *δύναμις*, power). A term applied to flowers having four stamens, of which two are short and two are long.

Die (Fr. *dé*). In Coinage, is the instrument by which the impressions are given upon the various denominations of coin. The following is an outline of the *die manufacture*, as conducted in her majesty's Mint: The engraver selects a forged plug of the best cast steel of proper dimensions for his intended work; and having carefully annealed it, and turned its surfaces smooth in the lathe, proceeds to engrave upon it the intended device for the coin; the Queen's head, for instance. When this is perfect, the letters are put in, and the circularity and size duly adjusted; it is then hardened, and is termed a *matrix*. Another plug of soft steel is now selected; and the matrix being carefully adjusted upon it, they are placed under a very powerful fly-press, and two or three blows so directed as to commence an impression of the matrix upon the plug; this is then annealed, and the operation repeated till the plug receives a perfect impression of the work upon the matrix. This impression is of course in *relief*, the original work upon the matrix being indented, and produces what is termed the *punch*. This, being duly shaped in the lathe, is hardened, and is employed in the production of impressions in soft steel, or *die*, which being properly turned and hardened, are exact *fac-similes* of the original matrix, and are used in the process of *coinage*. When a pair of dies are made of good steel duly hardened and tempered, and are carefully used, they will sometimes yield from two to three hundred thousand impressions before they become so far worn or injured as to require to be removed from the coining presses.

Dieffenbachia (named after M. Dieffenbach). A genus of *Araceæ* belonging to the tropics of the New World, and consisting of herbs having tall fleshy stems, rather large leaves often variegated, and spadices enclosed in yellowish spathe. The female flowers are confined to the base of the spadix. *D. seguina* is the Dumb Cane of the West Indies, a virulent plant, whose juice is so acrid as to render speechless for days those who may happen to bite the stems, which, when the leaves are gone and the ring-like markings become evident, bear some resemblance to those of the Sugar Cane.

Dielectric. A body which admits of the force of electricity acting through it.

Dioresilla. A term invented by Mirbel to denote a many-celled superior fruit; the cells being dry, indehiscent, few-seeded, and cohering by a common style round a common axis, as in *Malva*.

Diesis (Gr.). In Music, an interval less than a comma. The harmonical diesis is the difference between a greater and a less semitone.

Diespiter. [JUPITER.]

x x 2

DIET

Diet (Low Lat. *dieta*, from *dies*, a day Ger. Reichstag). A name given to the principal national assembly in many countries of modern Europe.

By the usage of the *German Empire*, two diets were summoned every year by the emperor, besides such as were convoked on extraordinary occasions. There were three chambers—1. That of the electors [Electorat], 2. That of the sovereign princes, divided into two spiritual and four temporal benches. The counts of the empire voted collectively in four benches or divisions, and not as individuals; the prelates and the abbots in two. 3. The chamber of the imperial cities, divided into the Rhenish and the Swabian benches. The diets, together with the emperor, exercised the prerogatives of sovereignty. A decree of the diet was termed a *recess of the empire*. The diet of the modern Germanic Confederation is a meeting of plenipotentiaries, permanently assembled in the city of Frankfort-on-the-Maine. [CONFEDERATION.]

The diet of Hungary is, according to the constitution, composed of the king (emperor of Austria) and the estates. The latter consist of the higher clergy, the magnates, the two courts of appeal, and two representatives from each chapter, county, city, and privileged district. They are divided into two chambers called *tabula*.

The diet of Switzerland is composed of the representatives of the cantons, and manages such affairs as by the federal constitution are exempted from the jurisdiction of those several independent states. It is held every two years, alternately at Zurich, Berne, and Lucerne, which are termed the presiding cantons (*vorort*). The *schultheiss* or governor (chief executive magistrate) of the presiding canton is *landamman* of Switzerland for the time being. Each canton has one vote in the diet.

From a very remote period, down to 1832, Poland had national assemblies, or *diets*, which were of two sorts, *ordinary* and *extraordinary*. The ordinary diet was held every two years, and usually at Warsaw; though it was expressly enacted that every third meeting should be convened at Grodno, in Lithuania. The duration of its sitting was restricted to six weeks, and could not, under any pretext, be protracted beyond this period. The diet was composed of a selection from the nobility, who formed what was called the senate, and of the deputies returned by each of the palatinates and districts of the country. The number amounted to about 400. The period of its meeting was fixed by the king, who presided over its deliberations; except during an interregnum, when the business of summoning the diet devolved on the archbishop of Gnesna. The *extraordinary* diets differed from the *ordinary* chiefly in this, that there was no stated period for the former being summoned together, that they were convoked only to listen to propositions from the throne, and lasted only four days.

DIFFERENCE

As is well known, the throne of Poland was not hereditary, but elective; and, on the occasion of choosing the sovereign, the Polish diets were held in the open country, and were attended by all the nobility on horseback, armed and equipped as if for battle. On this subject the reader is referred to a work of great ability, by De la Birardiére, entitled *Histoire des Diètes de Pologne, pour les Elections des Rois, depuis 1572 jusqu'en 1674* (8vo. Paris 1679). *Dietines* was the name given to the particular assemblies of the Polish nobility in which deputies were elected to serve in the ordinary diets, and to represent the wishes and interests of their constituents. In these dietines every gentleman possessing an estate of three acres had the right of voting, and every deputy was chosen by the majority of suffrages.

Diet Drink. Alterative decoctions taken in considerable quantities; such as decoction of sarsaparilla, sassafras, dandelion, &c. *Lisbon diet drink* nearly resembles the compound decoction of sarsaparilla of the London Pharmacopœia.

Dietetics (Gr. *diæteritês*). That part of medical science which relates to the diet or ordinary food. [DIGESTION and FOOD.]

Diethylamine. A compound which may be represented as ammonia, two atoms of whose hydrogen have been replaced by two of ethyl. It is a colourless volatile inflammable caustic liquid.

Diethylin. A colourless liquid derived from two atoms of alcohol and one of glycerin.

Dieu et Mon Droit (Fr. *God and my right*). The motto of the royal family of England. It was first assumed by Richard I., to intimate that he held his sovereignty from God alone, and not in vassalage to man; and it would seem that it fell into desuetude among the immediate successors of that prince, and remained so till the reign of Edward III., by whom it was revived when he first claimed the crown of France. Since that period, if we except the reigns of Elizabeth, William III., and Anne, the first and last of whom used the motto, *Semper eadem*, and the second, though only in his private capacity, *Je maintiendray*, *Dieu et mon droit* has always formed the royal motto of England.

Disfarreatio (Lat.). The Roman ceremony for dissolving marriages contracted by *confarreatio*. Such marriages could be made only by patricians, and the confarreatio was a religious ceremony in which *panis farreus*, or corn bread, was employed in the presence of ten witnesses, and certain words were spoken, which brought the woman in *manum viri*, or under the authority of her husband.

Difference (Lat. *differentia*). In Arithmetic and Algebra, the excess of one quantity over another, or the result of the operation of subtraction.

Difference. In Logic, one of the predicates. It is that particular quality which distinguishes the subject from all others, when

DIFFERENCES

contemplated from that point of view in which we are then regarding it; and is said, logically, to be part of the essence of the subject. The genus, together with the difference, is said to make up the species; the species, with the difference, to make up the lower species, or the individual: e.g. To the genus metal add the difference 'susceptible of magnetic attraction,' and we obtain the species iron, which is distinguished from all other metals by that peculiarity.

Differences. In Heraldry, devices borne on the escutcheon to indicate the part of a family to which the bearer belongs. This has been effected by various methods—at present by what are termed *brevets*, *marks of filiation*, or of *cadency*; being small charges placed conspicuously in the shield. The eldest son bears a label of three points; the second, a crescent; the third, a mullet; the fourth, martlet; the fifth, an amulet or small ring; the sixth, a fleur-de-lys; the seventh, a rose; the eighth, a cross moline; the ninth, a double quatrefoil. The family of the second son repeat these differences on their own paternal mark of filiation: e.g. the second son's first son bears a crescent ensigned with a label, and so on of the rest. Females do not bear differences.

Differences, Calculus of. The science whose object is the investigation of the ratios which exist between the simultaneous increments or changes of mutually dependent quantities. It is distinguished from the differential calculus by the circumstance that in the latter the *limits* of these ratios alone enter into consideration. If u_x denote any function of x , say the x^{th} or general term of a series, then the difference $u_{x+1} - u_x$ is denoted by the symbol Δu_x , and Δ is the symbol of the fundamental operation in the calculus of differences, analogous to $\frac{d}{dx}$ in the differential calculus. The former indeed corresponds to $\frac{\Delta}{\Delta x}$, the constant difference Δx being supposed equal to 1, so, without loss of generality, it always may be. The *first difference* Δu_x being itself a function of x , the operation Δ can of course be repeated upon it; the result is called the *second difference*, and is denoted by $\Delta^2 u_x$ or $\Delta^2 u_x$. In the same way we proceed to differences of higher orders, the symbols of the corresponding operations being subject to the ordinary index-law $\Delta^m \Delta^n = \Delta^{m+n}$. The symbol Δ is also distributive, that is to say, $\Delta(u_x + v_x) = \Delta u_x + \Delta v_x$, and it enters into combination with constant quantities just as a symbol of quantity would, since it possesses the commutative property $\Delta a u_x = a \Delta u_x$. The *succeeding value* to u_x is often denoted by u_{x+1} , and since

$$D u_x = u_{x+1} = u_x + \Delta u_x$$

we see that the operative symbol D is connected with Δ by means of the relation $D = \Delta + 1$, and consequently possesses the same three charac-

DIFFERENCES OF ZERO

teristic properties. On the other hand, by Taylor's theorem, in its symbolical form, we have $D = e^{\frac{d}{dx}}$. The operations D , Δ and $\frac{d}{dx}$ are convertible one into the other by means of these remarkable and important relations. For instance, by the first relation we have at once

$$u_{x+1} = D u_x = (1 + \Delta)^1 u_x =$$

$$= u_x + \Delta u_x + \frac{\Delta(\Delta-1)}{1 \cdot 2} \Delta^2 u_x + \&c. \dots$$

a formula by which the n^{th} succeeding value u_{x+n} is expressed in terms of u_x , and its first n successive differences. Conversely

$$\Delta^2 u_x = (D-1)^2 u_x$$

$$= (D^2 - 2D + 1) u_x = \frac{\Delta(\Delta-1)}{1 \cdot 2} D^2 u_x + (-1)^2 u_x$$

$$+ (-1)^2 u_x$$

an important formula, by means of which differences of any order can be calculated when a series of successive values is known.

The differences hitherto considered have been *total ones*, the subject u_x being a function of a single variable x . With functions of two or more variables arise *partial differences*, by which term is to be understood the differences formed on the hypothesis that one only of the variables suffers a change of value. Of English works on the calculus of differences, we may mention De Morgan's *Differential and Integral Calculus*, and Sir J. Herschel's appendix to the English translation of *Lacroix*, as well worthy of careful study; but Boole's *Treatise on the Calculus of Finite Differences*, London, 1860, contains the most recent and complete exposition of its principles and methods.

Differences, Equation of. [Equation of Differences.]

Differences of Zero. Important numbers which frequently occur in the theory of series and in the calculus of differences. Their origin may be understood by considering the series of x , numbers 0^{th} , 1^{th} , 2^{th} , 3^{th} , &c. If under each of these terms the difference between it and the succeeding term is written, a series of *first differences* will be obtained, and from the terms of this series, a series of *second differences* may be deduced in a similar manner, and so on; the terms of the series of m^{th} differences will all be equal, so that there will be no series of $(m+1)^{\text{th}}$ differences. A table being thus formed, the numbers under 0^{th} , in the first column, will be the *differences of zero* corresponding to the index m ; they are usually represented by the symbols $\Delta^0 0^{\text{th}}$, $\Delta^0 1^{\text{th}}$, $\Delta^0 2^{\text{th}}$, &c. $\Delta^0 0^{\text{th}}$, the last of which has the value $1 \cdot 2 \cdot 3 \dots m$.

In general

$$\Delta^2 u_x = (x+n)^m - n(x+n-1)^m + \frac{\Delta(\Delta-1)}{1 \cdot 2} (x+n-2)^m \&c.$$

[DIFFERENCES, CALCULUS OF]; so that, putting

DIFFERENTIAL CALCULUS

$$x=0 \Delta^n 0^n = n^n - n(n-1)^{n-1} + \frac{n(n-1)}{1 \cdot 2} (n-2)^{n-2} \dots + (-1)^{n-1} n 1^n.$$

Differential Calculus. The name by which one of the most important branches of the higher mathematics is usually designated, and in which magnitudes are contemplated as susceptible of *continuous* growth.

The most important of the terms which are employed in the calculus will be elsewhere explained; moreover, as there are numerous treatises on the subject, a few general remarks, relative to its nature and history, will here suffice. Broadly speaking, the object of the differential calculus may be said to be the determination of the ratios of the differences of mutually dependent variable magnitudes, on the supposition that these differences become *infinitely small*; an hypothesis which gives rise to considerable abbreviations in the general calculation of differences.

The infinitely small variation, increment or decrement, of a quantity is termed its *differential*, and is expressed by writing the letter *d* before the magnitude or function: thus *dx* signifies the differential of the variable magnitude *x*, *d(xy)* the differential of the product of the two variables *x* and *y*, and so on. The differential of a differential is called the *second differential*, and, *x* being the variable, is denoted by *ddx*, or more briefly by *d²x*. In a similar manner *dⁿx* is the *n*th differential of *x*. The letter *d* was introduced by Leibnitz, and is now adopted by all writers as the symbol of differentiation.

The differential calculus, although invented by Leibnitz, was reduced to a systematic form, and greatly extended, by the two celebrated brothers James and John Bernoulli. Some years, however, before Leibnitz fell on the discovery, the method of *fluxions*, with which the differential calculus agrees in every respect, excepting its notation and the manner in which the principles are usually explained, had been invented and applied by Newton. This circumstance gave rise to a dispute, which was long carried on with great acrimony, between the mathematicians of England on the one hand, who put forward the claims of Newton for the honour of the invention, and those of France and Germany on the other, who gave the merit of it to Leibnitz. It was established beyond doubt that Newton was in possession of his method before it had been thought of by Leibnitz: the only question, therefore, was whether Leibnitz received such hints or information respecting the nature of Newton's method as were sufficient to guide him to its discovery. Of this there is no evidence, and extremely little probability; accordingly, mathematicians have long agreed to recognise the claims of Leibnitz as an independent inventor. It was only at the commencement of the present century that the notation *dx*, introduced by Newton for the fluxion (differential) of *x*, was finally replaced by the more convenient notation of Leibnitz and the Bernoullis.

DIFFERENTIAL COEFFICIENT

Differential Coefficient. The limit of the ratio which the increment of a function bears to that of its independent variable, when the latter is conceived to diminish indefinitely. Thus *y = F(x)* being the function, and Δx an increment of *x*, the limit to which the ratio

$$\frac{F(x + \Delta x) - F(x)}{\Delta x}$$

approaches as Δx diminishes is the differential coefficient of *y*, and is denoted by the symbol $\frac{dy}{dx}$, which latter, accordingly, must not be regarded as an ordinary fraction, but as the symbolised result of the complex operation, above defined, upon the given subject *y*. This operation is the fundamental one of the differential calculus, and is itself denoted by the symbol $\frac{d}{dx}$; the result is, in general, another function of *x*, in fact the *derived function* $y' = F'(x)$, and may be operated upon in the same manner a second time. Two such successive operations are denoted by the symbol

$$\frac{d}{dx} \frac{d}{dx} \text{ or } \frac{d^2}{dx^2},$$

and the result $\frac{d^2y}{dx^2}$ is termed the *second differential coefficient* of *y*. It is important to observe that the operative symbol $\frac{d}{dx}$ not only obeys the ordinary *index law*, expressed by

$$\frac{d^m}{dx^m} \frac{d^n}{dx^n} = \frac{d^{m+n}}{dx^{m+n}},$$

but is also *distributive*, that is to say,

$$\frac{d}{dx} (u + v) = \frac{du}{dx} + \frac{dv}{dx};$$

it is, moreover, *commutative* with respect to symbols of *constant* or *invariable* quantities; thus

$$\frac{d}{dx} (au) = a \frac{du}{dx}.$$

Hence it follows that the operative symbol $\frac{d}{dx}$ combines, precisely as a quantitative one would do, with other symbols of constant quantities. Thus the operation

$$\frac{d^2}{dx^2} + 2 \frac{d}{dx} - 3,$$

performed on any function of *x*, is equivalent to the operations

$$\left(\frac{d}{dx} - 1\right) \text{ and } \left(\frac{d}{dx} + 3\right)$$

performed successively. Important applications and extensions of this principle are made in the differential calculus. [LINEAR]

The differential coefficient of a function *z* of two or more variables *x*, *y*, &c., formed on the hypothesis that one only, *x*, of the latter changes its value, is termed a *partial differential coefficient* of *z* according to *x*, and is represented

DIFFERENTIAL EQUATION

by the symbol $\left(\frac{as}{dx}\right)$ or simply by $\frac{as}{dx}$ when more precise definition is not needed. The partial differential of $\frac{ds}{dx}$ taken with respect to the variable y is of course represented either by

$$\frac{d^2s}{dy\,dx} \text{ or } \frac{d^2s}{dx\,dy},$$

and so on.

Differential Equation. A relation connecting the differentials or differential coefficients of variable functions with each other, and with the functions themselves. The object contemplated in the study of such equations is, usually, to discover the most general relation between the primitive variables, which by differentiation would lead to the differential equation under consideration. This general relation is called the *complete primitive*, when the direct operations are contemplated, which, when performed upon it, lead to the differential equation, and the *complete solution* or *final integral* when the inverse procedure corresponds to the order of thought. Differential equations are divided into two great classes, *ordinary* and *partial*; the first have reference to a single independent variable, whilst the latter involve partial differential coefficients, and indicate, consequently, the existence of two or more independent variables. Differential equations of both kinds are further distinguished by their *order* and *degree*, which terms are no longer synonymous as in algebra. The *order* of a differential equation is the same as that of the highest differential coefficient it contains, whilst its *degree* coincides with the highest power to which this differential coefficient of highest order is raised, when the equation is reduced to a rational form. Certain special forms of differential equations have received distinctive names. Amongst these may be mentioned *exact* differential equations, which are obtainable immediately by the differentiation of some function which has a constant value; and *homogeneous* differential equations, which are characterised by the homogeneity either of the several terms or of certain factors of these terms. The term *linear*, as applied to differential equations in two variables, does not mean, precisely, *of the first degree*; it denotes merely that the equation is of the first degree in the dependent variable and its differential coefficients. Thus, if $X, X_1, X_2, \&c.$ denote functions of x solely, the equation

$$\frac{d^2y}{dx^2} + X_1 \frac{d^{n-1}y}{dx^{n-1}} + \dots + X_n y = X$$

would be called *linear*.

When from a primitive equation connecting x and y with n arbitrary constants, r other equations are derived by successive differentiation, the elimination of any r of the n constants from the system of $r+1$ equations thus obtained, will lead to a differential equation of the r^{th} order containing $n-r$ constants. By selecting all

DIFFERENTIAL THERMOMETER

possible groups of r constants for elimination, it will clearly be possible to form

$$\frac{n(n-1) \dots (n-r+1)}{1 \cdot 2 \dots r}$$

such equations, but of this number only $r+1$ will be independent. There will further be one and only one differential equation of the n^{th} order, free from arbitrary constants. Conversely, an ordinary differential equation of the n^{th} order in two variables implies the existence of n independent *first integrals* or differential equations of the $(n-1)^{\text{th}}$ order, each containing an arbitrary constant, and of one final integral involving n arbitrary constants.

Partial differential equations may arise either from the elimination of arbitrary functions or of arbitrary constants from a primitive relation between the variables. In the former case this relation is called the *general*, in the latter the *complete primitive*. There does not exist, however, the same relation, as in ordinary differential equations, between the order of a partial differential equation and the number of arbitrary functions in its general primitive. For instance, it is not always possible from a general primitive, involving two arbitrary functions of x, y, z , to obtain a partial differential equation of the second order free from arbitrary functional symbols.

The methods of solving the most important and frequently occurring forms of differential equations are given in all good treatises on the calculus. Of the works specially devoted to the subject, the most recent one is that by Prof. Boole (London 1859), which contains valuable chapters on the application of symbolical methods. Prof. Cayley's Reports on the Recent Progress of Theoretical Dynamics may be mentioned, too, as containing very valuable information on the higher branches of the subject; they will be found in the *Proceedings of the British Association*, 1857-63.

Differential Galvanometer. [GALVANOMETER.]

Differential Resolvent. An algebraic equation, of the n^{th} degree, being given, whose coefficients are functions of a single parameter, its *differential resolvent* is a certain linear differential equation of the $(n-1)^{\text{th}}$ order which is satisfied by each of the roots of that equation. Messrs. Cockle and Harley were the first to investigate the properties of the differential resolvent; their researches will be found in *Phil. Mag.* 1862, and *Quart. Jour. Math.* 1862-3. Prof. Boole's last contribution to the *Phil. Trans.* (1865) was on this subject.

Differential Thermometer. An ingenious instrument, of great use in experimental philosophy, for measuring very small differences of temperature; invented and first applied by Sir John Leslie, though the idea of an instrument of the same kind seems to have long before suggested itself to Sturmius. The differential thermometer is described by Leslie, in his *Experimental Inquiry into the Nature and Pro-*

DIFFERENTIATION

pagation of Heat, nearly as follows: Two glass tubes of unequal lengths, each terminating in a hollow ball, and having their bores somewhat widened at the other ends, a small portion of sulphuric acid tinged with carmine being introduced into the ball of the longer tube, are joined together by the flame of a blow-pipe, and afterwards bent into nearly the shape of the letter U; the one flexure being made just below the joining, where the small cavity facilitates the adjustment of the instrument, which, by a little dexterity, is performed by forcing with the heat of the hand a few minute globules of air from the one ball into the other. The balls are blown as equal as the eye can judge, and from four-tenths to seven-tenths of an inch in diameter. To one of the

legs of the thermometer a scale is attached; and the liquid, contained in the tube is so disposed that it stands in the graduated leg opposite the zero of the scale, when both balls are exposed to the same temperature. From this construction of the instrument, it is easy to see that it is affected by the

difference only of heat in the two balls. As long as both balls are of the same temperature, whatever this may be, the air contained in the one will have the same elasticity as that contained in the other; and consequently the intercluded coloured liquid, being thus pressed equally in opposite directions, must remain stationary. But if, for instance, the ball which holds a portion of the liquor be warmer than the other, the superior elasticity of the confined air will drive it forward, and make it rise in the opposite branch above the zero, to an elevation proportional to the excess of elasticity or of heat. Sulphuric acid is chosen as the liquor best adapted to the purpose; because it is not vaporisable, and consequently does not by its vapour affect the pressure of the air above it. The carmine is used to render it more easily visible.

Differentiation. In Mathematics, the operation by which the differential of a function is determined, and of which d is the symbol. The allied operation which leads to the determination of the derived function or *differential coefficient*, and which is

symbolised by $\frac{d}{dx}$ is usually termed *derivation*.

By the *partial* differentiation of a function of two or more independent variables, is understood the differentiation of that function on the hypothesis that one only of these variables suffers a change of value. [**DIFFERENTIAL COEFFICIENT.**]

Finite differentiation, again, denotes the operation by which the *differences* of a function, corresponding to a finite difference of the variable, is determined. The latter difference

DIAGRAMMA

being unity, the symbol of finite differentiation is Δ . [**DIFFERENCES, CALCULUS OF.**]

Diffusum. A term applied to a substance formed by long boiling a solution of alloxanic acid. It is represented as $C_6H_8O_8N_4$.

Diffraction (Lat. *dis*, and *frango*, *I break*). In Optics, a species of deviation or deflection which the rays of light undergo in passing very near to any opaque body. This phenomenon was first observed by Grimaldi, who described the principal appearances with sufficient accuracy; but Newton first attempted to explain its cause by the general properties of light. His experiments are detailed in the last book of his *Optics*. In order to exhibit the phenomena of diffraction, let a beam of solar light, reflected horizontally, be admitted into a dark chamber through a small round hole, and received on a white vertical wall. If the hole have a sensible diameter, the image of the sun thrown on the wall will suffer no sensible alteration of colour; but if we place in the axis of the beam of light, and at a distance of five or six feet from the hole through which it is admitted, a metallic plate, having a puncture made in it by the point of a very fine needle, and intercepting all other light than that which passes through the puncture, the appearance on the wall will no longer be a circular spot of white light only; it will be surrounded with several concentric coloured rings, covering a space far exceeding in extent that which the solar beam would have occupied if the rays of which it was composed had followed their rectilinear direction. By substituting a very narrow slit for the puncture in the metallic plate, or several punctures or slits very close to each other, and arranged in a certain manner, some of the most beautiful phenomena of optics are exhibited.

Diffusion of Gases. When two gaseous bodies which do not act chemically upon each other are mixed together in any relative proportions, they gradually diffuse themselves through each other; so that after a sufficient time has elapsed for the purpose, whatever may have been their relative densities, they are found intimately blended: the heavier gas does not fall, nor does the lighter one float. Dalton, therefore, has appropriately represented gaseous bodies as acting as *vacua* to each other. Professor Graham's researches have lately thrown much new light upon this subject, and he has determined the laws of *gaseous diffusion* by a series of well-conceived experiments. (Graham's *Elements of Chemistry*, vol. i. p. 71.) [**GASES, DIFFUSION OF.**]

Digamma (Gr. *double gamma*, Γ , so called from its representing two gammas, thus, $\Gamma\Gamma$). The name given to the form of that letter in the ancient Greek alphabet which corresponds in appearance generally to the Latin F. This letter appears to have occupied the sixth place in the alphabet, and was most prevalent in the *Æolic* dialect, though some grammarians contend that it was common to all the dialects of Greece in their more ancient mode of pronun-

DIGASTRIC MUSCLE

cision. As the Latin language approximated more nearly to the Æolic than to any of the other Grecian dialects, the use of the digamma is very prevalent in many Latin words, and the facility with which it was there interchanged for V, both at the commencement and in the middle of words, will be at once apparent from the following examples: Gr. *ἄρ*, spring, Æol. *ἄρ*, Lat. ver; Gr. *ἑσπερ*, evening, Æol. *ἑσπερ*, Lat. vespers; Gr. *οἶνος*, wine, Æol. *ἑλινος*, Lat. vinum. It must not, however, be supposed that the digamma is to be regarded as simply synonymous with the labial semi-vowel v. It represents at least three different letters in the ergate languages, namely, v, s, y. (Grote's *History of Greece*, part i. ch. xxi.)

Digastrie Muscle (Gr. *δισ*, and *γαστήρ*, belly). A double muscle, situated externally between the lower jaw and mastoid process; it is attached to the *os hyoides* in the human subject at the middle of its course. It pulls the lower jaw downwards and backwards; and when the jaws are shut, it draws the larynx, and with it the pharynx, upwards in the act of swallowing.

Digenesis (Gr. *δισ*, and *γενεσις*, birth). Professor van Beneden applies this term to the generation of those *Entozoa* in which intermediate forms are interpolated alternately. Professor A. Thomson applies it to origin from two parents, each concerned in the reproductive act.

Digest (Lat. *digestus*, brought into order). Several compilations of the Roman Law have been so called; but the best known is that which was made by order of the emperor Justinian. It is also termed the *Pandects*, from the Greek words, *πᾶν*, all, and *δέκτα*, *to receive*; signifying the general nature of the collection. The care of this great compilation was intrusted by the emperor to Tribonian, with seventeen associates. It was completed in three years, and published A.D. 529. It contains the best decisions and opinions of former jurists, collected, it is said, from more than 2,000 volumes; and follows the same arrangement as the code of the same emperor, which had appeared in 529. The *Pandects* of Justinian, according to the commonly received story, were neglected in the Eastern Empire shortly after the decease of that emperor, and were wholly lost in the West until the accidental discovery of a MS. at Amalfi in 1130. But this tradition is now generally believed to rest on no solid foundation. [LAW, CIVIL.] (Gibbon, cap. xlv.; Savigny *On the Roman Law*.)

Digester. A strong iron or copper vessel with a tightly adjusted lid, furnished with a safety valve, in which bodies may be subjected to the action of high-pressure steam, or of water above its ordinary boiling temperature. It is known as *Papin's Digester*.

Digestion (Lat. *digestio*). The general process by which food is converted into *chyme* in the stomachs of animals, and by which it is rendered fit for the production of *chyle*, and

DIGITALIS

ultimately of blood. The term *digestion* is also more generally applied to the entire functions of the intestinal canal. The phenomena of digestion, though exclusively chemical, are also under the immediate influence of vitality, and are consequently perfectly different from any changes which the food suffers out of the body; hence the unsatisfactory conclusions of the older physiologists, who considered attrition, fermentation, and similar mechanical and chemical processes as sufficient to account for the extraordinary changes that are produced. It has been clearly ascertained that the influence of the nervous system is essential to the due performance of the functions of the stomach; and that when the brain, or the nerves that supply that viscus, are either injured or divided, digestion is either impaired or altogether suspended, and the food then ferments and putrefies instead of digesting. It has been said that the transmission of a current of electricity through the nerves is equivalent to their connection with the brain, and that under such circumstances the stomach, notwithstanding the division of its nerves, continues its functions; but these, and other statements in which electricity is said to be equivalent to the nervous and cerebral agency, require much more extended experimental proofs than they have hitherto received, before they can be admitted as true interpretations. It may, however, be concluded that nerve force, though not identical with electric force, may be another mode of action of the same common force. [NUTRITION.]

Digestion. In Surgery, this term was formerly applied to the treatment by which wounds or ulcers were brought into that state in which they form healthy pus: the remedies or applications promoting this object were termed *digestives*.

Digit (Lat. *digitus*, finger). In Arithmetic, one of the ten symbols, 0, 1, 2, 3, &c., by which all numbers are expressed. By astronomers the term is used, in speaking of eclipses, to denote the twelfth part of the diameter of the sun or moon. Thus, the eclipse is said to be of ten digits, if ten parts out of twelve of the diameter are concealed.

Digitalia. A very poisonous vegetable alkaloid, procured from the leaves of the *digitalis*.

Digitalis (Lat.). This genus of *Scrophulariaceae* is represented by the well-known Foxglove, *D. purpurea*, one of the finest of our native plants, found in woods and by roadsides. The plant has a tuft of large ovate oblong root-leaves, from among which rise the erect flower-stems, bearing a long one-sided raceme of drooping irregularly bell-shaped flowers of a rich pinkish-purple, paler inside, and marked there with dark spots. The Foxglove possesses powerful medicinal properties, due to the presence of an extremely poisonous principle, called *digitalia*. It is used in dropsy and heart disease, but requires great caution in its administration. It diminishes the fullness and frequency of the pulse, and increases the flow of urine. In cases of poisoning

DIGITATE

by this plant, the stomach-pump, or emetica, should be resorted to, while ammonia and similar stimulants should be given to prevent fainting.

Digitate (Lat. *digitatus*, *having fingers*). In Botany, the term used when several distinct leaflets radiate from the end of a leaf-stalk, as in the Horse-chestnut.

Digitigrades, **Digitigrada** (Lat. *digitus*, and *gradior*, *I walk*). The carnivorous quadrupeds which walk on the extremities of their digits. An artificial group of *Carnivora* is so called in the system of Cuvier.

Digitlyph (Gr. *δύλυφος*, *doubly indented*). In Architecture, a projecting face with two panels sunk thereon, sometimes introduced on the entablature of the Doric order instead of the triglyphs.

Dignitary. In the Canon Law, this term signified originally a person who held an ecclesiastical benefice or dignity, which gave him some preeminence above ordinary priests. To this class exclusively belonged all bishops, deans, archdeacons, &c.; but it now includes also prebendaries and canons.

Digression (Lat. *digressio*, *a stepping aside*). In Astronomy, the apparent distance of the inferior planets Mercury and Venus from the sun. Mercury is never seen at a greater distance than about 28° from the sun; this is called its *greatest digression*: but on account of the great eccentricity of the planet's orbit, its maximum digressions are subject to considerable variation. The greatest digression of Venus is about $47\frac{1}{2}^\circ$, and it admits of a variation amounting to about $2^\circ 48'$. When the digression of an inferior planet attains its maximum, the visual ray along which it is seen is a tangent to the orbit, and the planet appears for some days nearly stationary. The more recent term *elongation* has now altogether taken the place of *digression*, and the term as expressing the greatest angular distance from the sun is confined to the inferior planets above named.

Dihedral Angle. In Geometry, denotes the mutual inclination of two intersecting planes; or more accurately the *quantity of turning*, around the intersection of two planes, which would be required to make one coincide with the other. It is obviously equal to the angle between the two lines drawn one in each plane, from any point of, and perpendicular to, the intersection of the two planes.

Dis Consentes. [CONSENTES DIS.]

Dike. A term employed by Geologists to express a kind of wall of mineral matter, cutting through strata in nearly a vertical direction; it is generally applied to masses of eruptive matter of subterranean origin, such as trap and green-stone dikes. There is little difference between dikes and veins; for, to quote Lyell, dikes are generally of larger dimensions, and have their sides parallel to a considerable distance; while veins have generally many ramifications, and these often thin away into slender threads. The two designations are in fact nearly synonymous.

DILETTANTE

Dilapidation (Lat. *dilapidatio*). In Ecclesiastical Law, is where an incumbent of a benefice suffers the parsonage house or out-houses to fall down or be in decay for want of necessary repairs, or commits any wilful waste of the inheritance of the church. Proceedings against an incumbent for dilapidations must be in the spiritual court. Against his executors, the remedy is either by proceeding in that court, or the successor may have an action of debt or on the case for damages at common law.

Dilatation. [EXPANSION.]

Dilemma (Gr.). In Logic, a species of argument in the form of a complex conditional syllogism. [SYLLOGISM.] It has been divided by logical writers into—1. The simple constructive dilemma, in which the major premiss contains several antecedents all with the same consequent; the minor premiss grants that some one of these antecedents is true; and the conclusion infers that the common consequent is true: e.g. If A is B, C is D; and if X is Y, C is D; but either A is B or X is Y, therefore C is D. 2. The complex constructive dilemma, in which the several antecedents have each a distinct consequent; and it being granted that one antecedent is true, it follows that one consequent is true: e.g. If A is B, C is D; and if X is Y, E is F; but either A is B or X is Y, therefore either C is D or E is F. 3. The destructive dilemma, properly so called, has several antecedents with each a different consequent; and by denying the consequents disjunctively (i.e. denying that one or the other consequent is true) in the minor premiss, we proceed in the conclusion to deny the truth of one or the other antecedent: e.g. If A is B, C is D; and if X is Y, E is F; but either C is not D or E is not F, therefore either A is not B or X is not Y. Every dilemma may be reduced into two or more simple conditional syllogisms.

In the ordinary sense of the word, a dilemma is an argument in which two or more propositions are pressed upon the mind in such a manner that by granting which we will we are compelled to infer the same conclusion. One of the most celebrated dilemmas is that of the philosopher Protagoras in reference to his pupil Euathlus; for an account of which, see the *Athenian Letters*, vol. i. p. 149.

Dilettante (Ital.). A term naturalised in France, England, and Germany; signifying an amateur, chiefly of music, but also of the kindred sciences. There has existed in England, since the year 1760, a society called the *Dilettanti Society* (originally instituted by a gentleman who had travelled in Italy), for perpetuating in each other's company the pleasure they had derived from their residence in that country; but its objects soon became materially extended; and it has acquired universal celebrity by the liberality with which it has devoted its funds to the purposes of science and art. Some of the most famous travellers in Greece and Asia Minor, among whom we may

mention Chandler, have been sent out at the sole expense of the Dilettanti Society; and many works illustrative of art and science, which would otherwise in all probability never have seen the light, have under their auspices been given to the world.

Diligence. In Scottish Law, a general term, comprehending the process of law by which persons, lands, or effects are seized in execution or in security for debt. It is divided into that against the *heritage*, that against the *movables*, and that against the person of the debtor; of each of which there are several species [INHIBITION; ADJUDICATION; POINDING; SEQUESTRATION; HORNING.] Diligence is also the name of the warrants issued by courts for enforcing the attendance of witnesses, or the production of writings.

Dill Seed. The seed of the *Anethum graveolens*, or Common Dill. This plant is grown for the supply of the medical market with its seeds: they are warm aromatics, with something of the caraway flavour, and yield *dill water*, and an essential oil, when distilled with water. Dill water is a useful remedy in flatulency and gripes of children.

Dilleniaceæ (Dillenia, one of the genera). A natural order of chiefly arborescent hypogynous Exogens inhabiting the hotter parts of the world. They are allied to *Magnoliaceæ*, from which they are distinguished by their want of stipules, and the quinary arrangement of the parts of fructification. They differ from *Ranunculaceæ*, to which they are also akin, in their persistent calyx and in their habit, and are universally characterised by the presence of an aril. Their properties are generally astringent.

Dillinite. A mineral from Dillna, near Schemnitz. It appears to be a hydrated silicate of alumina. [COLLYRITE.]

Diluents (Lat. *diluo*, *I wash away*). Water and aqueous drinks, which increase the secretion of urine and the perspiration, and appear to dilute the fluids of the body, are medically spoken of as *diluents*.

Diluvial Formations. Deposits that are the result of an unusual and extraordinary rush of water, carrying with it all kinds of material removed from the surface, or torn up during the progress of a wave. Diluvial action may result from heavy rains, the melting of snow, submarine earthquakes, or other causes. The material accumulated in this way is called *DILUVIUM*.

Diluvium (Lat.). A term applied by the older geologists to distinguish certain gravels and comparatively recent deposits which appear to be the result of a rush of water, or *deluge*, from the comparatively smaller stones, fire sand, and mud washed down by rivers during their ordinary state, and called *alluvium*. This distinction between alluvium and diluvium has been much lost sight of, and the latter term is now chiefly used in reference to gravels of one geological period, namely, that of the Boulder clay. [BOULDER CLAY and DRIFT.]

Dimagnetite. A mineral composed of the two oxides of iron, found near New York.

Dimerana, Dimeræ (Gr. *δῖς*, and *μῆρς*, *thigh*). The name of a section of Coleopterans, comprehending those which have apparently only two joints in each tarsus; this structure, however, does not in point of fact exist there being always a third rudimental tarsal joint.

Dimidiato (Lat. *dimidiatus*, *halved*). In Botany, this term is used when one half of an organ is so much the smaller as to appear to be missing, as in the pinnæ and pinnales of some species of *Asplenium*, *Adiantum*, and *Lindsæa*.

Diminished Interval. In Music, an interval which is defective or short of its perfect quantity by a semitone.

Diminuendo (Ital.). In Music, an instruction to the performer to lessen the volume of sound from loud to soft, usually marked thus >.

Diminution (Lat. *diminutio*). In Architecture, the gradual decrease in the diameter of a column as it rises. [ENTASIS.]

DIMINUTION. In Music, the subject of a figure or canon is said to be taken in diminution when its notes are diminished in length, generally to one half or one quarter of their former time.

Diminutive. In Grammar, is applied to words which, by the addition of one or more syllables to those from which they are derived, soften the meaning or diminish their force and effect. Every language is in a greater or less degree susceptible of diminutives; but in this respect, as is well known, the Italian language surpasses all those both of ancient and modern times.

Dimissory Letters. LETTERS, DIMISSORY.]

Dimity (Gr. *δίμυρος*, *of two threads*). A cotton cloth of a thick texture, and generally striped or otherwise ornamented in the loom; it is chiefly used for articles of female dress, and for bed furniture and window curtains, and is very rarely dyed.

Dimorphine (Gr. *δῖς*, and *μορφή*, *form*). The name given by Scacchi to the Orpiment found with Realgar on Vesuvius, because he considered it to be a particular sulphide of arsenic susceptible of assuming incompatible forms.

Dimorphism. The property of assuming two distinct crystalline forms.

Dimorphodon (Gr. *δῖς*, *μορφή*, and *δούς*, *tooth*). In this genus of Pterosaurian reptiles, the teeth are of two kinds; a few at the fore part of the jaws are long, large, sharp-pointed, with a full elliptical base; behind them is a close-set row of short, compressed, very small lancet-shaped teeth. There is no evidence of a tail. Such animals are found in the lower lias of Dorsetshire and Lyme Regis.

Dimyarias, Dimyariæ (Gr. *δῖς*, and *μύς*, *a knot of muscle*). All those bivalves or conchifers are so called which have two distinct and separate adductor muscles, and consequently two corresponding muscular impressions on each valve.

DINOSAURIA

Dinosauria (Gr. *deinos*, terrible, and *sauros*, lizard). An order of extinct reptiles, characterised by cervical and anterior dorsal vertebrae with par and diapophyses, articulating with bifurcate ribs; dorsal vertebrae with a neural platform, sacral vertebrae exceeding two in number; body supported on four strong unguliculate limbs. The genera *Iguanodon*, *Hylaeosaurus*, *Scelidosaurus*, and *Megalosaurus* form the solitary gigantic representatives of the order. The Dinosaurian reptiles are found in the mesozoic strata from the Lias to the Wealden inclusive.

Diocese (Gr. *diokēsis*). The territorial extent of a bishop's jurisdiction, embracing several parishes or parishes. As in early times the Christian converts were most numerous or most easily collected into a congregation in large towns, so in these towns did the bishop reside and minister to the faithful in his church, assisted by his priests and deacons. When the number of believers required the accommodation of additional temples, or congregations were formed in the neighbouring villages, the bishop was wont to appoint priests for their service, and the districts inhabited by these subsidiary congregations would become the parishes of his diocese.

Diodon (Gr. *diōs*, and *didōs*, a tooth; two-toothed). The name of a genus of Plectognathic fishes with undivided jaws, each with a single and continuous dental plate.

Diocleous or Dioleous (Gr. *diōs*, and *oikos*, a house). In Botany, that condition of structure in which the sexes of a plant are borne in different flowers by distinct individuals, as occurs in the Willows.

Dionysia (Gr. τὰ Διονυσία). Festivals of Dionysus, but more particularly those that were celebrated in Attica, which were three in number, distinguished by the following titles: 1. The Country Dionysia (τὰ κατ' ἄγρους); 2. Those in Lámne (a part of the city of Athens, where they were held), which were also called Lenæan (τὰ ληναία, from λῆνος, a wine-press); and 3. The Great Dionysia (τὰ μέγαλα). At all of these festivals the chief amusements consisted in the representation of stage plays; but the last was most celebrated, as then the great contests were held which brought out the marvellous powers of the tragic poets of Athens. [BACCHANALIA.]

Dionysus (Gr. Διόνυσος or Διδύσκος). A god who by the Greeks as well as the Romans was also called Iacchus and Bacchus. An almost inextricable mass of legend has gathered round the name of this god of wine and feasting. The mountain Nyssa, from which he is said to have derived his name, is found in many lands; and the myths which tell the several incidents of his life are as various as those which belong to Hercules. The so-called Homeric *Hymn to Dionysus* gives the Boeotian legend, in which Dionysus has the powers of transformation attributed to Proteus. According to this tale, he goes from Orchomenus to Egypt; and after travelling over many Eastern lands, returns to

DIOPTRICS

his old home with new religious rites, the introduction of which is in vain opposed by Pentheus. Finally, he leads out of Hades his mother Semele, who appears in the assembly of the gods under the name Thyoné.

Diophantine Analysis. A branch of Algebra which treats of indeterminate questions, of which the following may serve as a very simple example: *To find three (commensurable) numbers such that the sum of the squares of two of them shall be equal to the square of the third.*

The name *Diophantine* is derived from Diophantus, a mathematician of Alexandria, who is supposed to have lived in the third century of our era, and who examined and resolved a great number of questions of this nature in his celebrated treatise on arithmetic. Of this work, which exhibits the state of algebra among the Greeks, there are two editions: one by Bachet at Paris, in 1621; the other at Toulouse, in 1670, which is enriched by some valuable notes of Fermat. The student of indeterminate analysis will find the above subject treated in Legendre's *Théorie des Nombres*, Gauss' *Disquisitiones Arithmeticae*, and Euler's *Algebra*.

Diopside (Gr. *diōs*, and *opsis*, appearance; from its occasional transparency). A variety of white Augite. A silicate of lime and magnesia. It occurs in oblique rhombic prisms, which are colourless or of various shades of green, translucent or transparent, with a shining lustre, and generally striated longitudinally. The coarse and somewhat friable granular variety is called *White Coccolite*. Crystals are found in veins traversing Serpentine at Ala in Piedmont, and when transparent are sometimes polished and worn as gems.

Diopsis. The name of a genus of Dipterous insects, remarkable for having the eyes and antennae situated at the extremity of slender horny peduncles rising from the sides of the head, and equalling in some species the entire length of the body.

Diopase or Emerald Copper-ore (Gr. διόπτωμαι, to see through; because the natural joints are visible by transmitted light). A hydrated silicate of copper, composed, when pure, of 38·3 per cent. of silica, 50·3 oxide of copper, and 11·4 water. This beautiful but rare mineral is found in hexagonal crystals, and in small amorphous masses, of an emerald-green colour, with a vitreous lustre, and varying from transparent to translucent. It occurs in cavities in compact limestone at Altyn-Tübé, in the Kirghese steppes of Siberia; and, also, in the duchy of Nassau between Oberlahnstein and Braubach. [ACQUINTA.]

Dioptrics (Gr. διόπτρις, something transparent; from *diōs*, through, and *opsis*, I see). A branch of Optics, of which the object is to investigate and explain the effects of the refraction of light when it passes through different media, as air, water, glass, &c. Its principal application is to the construction of telescopes and microscopes, and other instruments which require the use of refracting lenses. The term

DIORAMA

is not much used by modern writers on optics, the phenomena to which it refers being treated under the general head of *Refraction*. [*LENS LIGHT; OPTICS; REFRACTION.*]

Diorama (Gr. *diá*, through, and *spáa*, see). A mode of painting or scenic representation, invented by two French artists, Daguerre and Bouton, and recently brought forward as a public exhibition in all the principal cities of Europe.

The peculiar and very high degree of optical illusion produced by the diorama depends upon two principles; the mode of exhibiting the painting, and the manner of preparing it. With respect to the first of these, the spectator and the picture are placed in separate rooms, and the picture viewed through an aperture, the sides of which are continued towards the picture, so as to prevent any object in the picture room from being seen excepting the painting itself. Into the room in which the spectator is placed no light is admitted excepting what comes through this aperture from the picture; he is thus placed in comparative darkness, and also (which contributes to the effect) at a considerable distance from the picture. The picture room is illuminated from the roof, which is glazed with ground glass: and the picture so placed that the light falls on it at a proper angle to be reflected towards the aperture. The roof, which is invisible to the spectator, is provided with an apparatus of folds or shutters, by which the intensity of the illumination may be increased or diminished at pleasure, and so modified as to represent, with great effect and accuracy, the different accidents of light and shade, or the changes of appearance depending on the state of the atmosphere; as bright sunshine, cloudy weather, or the obscurity of twilight.

The second principle consists in painting certain parts of the picture in transparency, and admitting a stream of light upon it from behind, which, passing through the picture, produces a brilliancy far surpassing what could be obtained by illuminating the picture in the ordinary way, and renders the relief of the objects represented much stronger and more deceptive. Hence, the diorama is peculiarly adapted for representing architectural objects, as the interiors of cathedrals, &c.

In order to render the exhibition more attractive, it is usual to present more scenes than one. This may of course be effected by removing one picture and substituting another; but with a view to prevent the illusion from being impaired by the accidents incidental to scene-shifting, a different method is sometimes resorted to. In the diorama formerly exhibited in the Regent's Park, the spectator was seated in a rotunda about forty feet in diameter, which turned round a vertical axis by means of machinery placed under the floor. There were two picture rooms contiguous to each other, each containing a view; and when the scene was to be changed, the rotunda was turned round until the aperture in front of the spectators which

DIP AND STRIKE

was first opposite to the opening into one of the picture rooms was placed directly opposite the opening into the other. This contrivance, however, it will be observed, is independent of the principles peculiar to the diorama.

Dioscoreaceae (Dioscorea, one of the genera). A natural order of Dictyogens, inhabiting the tropics, and agreeing with *Smilacae* by the genus *Tamus* in having an inferior fruit; but differing from it by the threefold character of inferior ovary, capsular fruit, and the albumen having a large cavity. The mealy tubers of various species of *Dioscorea*, under the name of Yams, form an important food in all tropical countries; and those of *D. Batatas*, a species recently obtained from China, are sometimes cultivated as an esculent in this country.

Dioscuri. [*NAMUS; POLYDUMUS.*]

Diosmin (Gr. *diós*, corn). A non-azotised matter contained in the leaves of Bucku, *Barosma crenulata*, *crenata*, &c.

Diospyros (a word coined from Gr. *dios*, divine, and *pyros*, wheat). A genus of arboreal *Ebenaceae*, mostly found in tropical Asia. They are dioecious plants with fleshy fruits, of which those of *D. Kaki*, the Chinese Date Plum, which is as large as an apple and bright red in colour, is made into sweetmeats by the Chinese. Those of *D. virginiana*, called the Persimon, are very austere and astringent, but when blotted become eatable; a kind of beer and also a spirit are sometimes obtained from them. The most important product of the genus, however, is its timber, ebony wood being obtained from several of the species, as *D. reticulata*, *Ebenum*, *Melanoxylon*, and *Ebenaster*. The hard black ebony consists of the heart-wood only, the sap-wood being soft and white. *D. quersita* yields the beautiful Calamander wood of Ceylon.

Dip. In Magnetism, the angle which a magnetic needle makes with the plane of the horizon, when poised on its centre of gravity and at liberty to turn in the vertical plane. [*DIPPING NEEDLE.*]

Dip of the Sea Horizon. In Navigation, the altitude of a heavenly body observed from a place above the surface of the sea, as from the deck of a ship, will evidently be greater than the altitude observed from the surface, since the observer brings the image of the body down to his horizon, which is lower than the horizon seen from the surface beneath.

The difference of the altitudes from this cause is called the *dip*. If the height of the spectator above the surface of the sea be *a* feet, then the correction for dip = $1.063 \sqrt{a}$. This value of the dip, however, is affected by refraction; but the amount of this cannot be very accurately determined on account of the variable nature of refraction at low altitudes. Experiments seem to show that refraction diminishes the amount of dip by about $\frac{1}{10}$ th of itself; hence the common table of dip used in Navigation may be computed from this formula: dip = $\frac{27}{10} \times 1.063 \times \sqrt{a} = .984 \sqrt{a}$.

Dip and Strike. The various strata of

DIPHANITE

the series of stratified rocks as they now appear are rarely quite horizontal or parallel to the earth's surface. When inclined to the horizon, they must cut the surface in a line, and this line, called the *OUTCROP* of the rocks, has a definite direction, which in geological language is called the *Strike*, from the German word *streichen*. The strike of rocks is therefore the compass direction of the intersection of their plane of stratification with the plane of the horizon.

When strata are moderately regular, the line of strike is a very useful fact to determine, as it enables the geologist to follow the same bed; and when concealed, covered up, or lost for a time, it suggests the place where he should seek for and endeavour to recover it.

But if beds have a strike, they must be inclined to the horizon. This is their dip [*Dip*], and must be at right angles to the strike, for that is the direction in which the plane of the bed dips down towards the interior of the earth. Beds dipping at a high angle are soon lost sight of, being generally covered up by other deposits of newer date. In the direction opposite to that of the dip, beds of older date come up from below or *crop out*. The series and sequence of deposits is made out by observations of dip and strike.

The direction of the inclination of a bed is necessarily at right angles to the line of strike. One observation therefore determines these two matters. The amount of inclination is required for practical purposes, and can be measured by a simple instrument. [*CLINOMETER.*]

Diphanite (Gr. *δῖς*, and *φαίνωμαι*, *I appear*). A mineral allied to *Margarite*, found in the Emerald mines of the Ural, on brown micaceous slate. The crystals (regular six-sided prisms with a perfect cleavage parallel to their basis) appear blue and transparent on one side, with a vitreous lustre; but on the cleavage faces, they appear white and opaque, when in tolerably thick laminae, and have a nacreous lustre.

Diphtheria (Gr. *διφθῆρα*, *a skin or membrane*). A disease attacking the throat, characterised by the exudation of lymph upon the tonsils and posterior fauces, extending frequently to the glottis and larynx, and sometimes even to the pharynx, œsophagus, and stomach. The external parts are frequently much swollen, deglutition and respiration are interfered with, and the patient may sink from suffocation. The disease appears to be the result of a poison introduced into the blood. Symptoms of great prostration are generally early observed, but mild cases now and then occur. It has been conjectured by some writers that diphtheria was known at the end of the sixteenth century in the Old and the New World, and that at a later date it destroyed the celebrated Washington, and also the Empress Josephine. The experience of the present generation commenced, however, but a few years ago, when the disease appeared at Boulogne, and ran an epidemic course through the north of France and the south of England. It received the name of

DIPHYDONTS

the Boulogne sore throat. In severe and in fatal cases this disease produces an excretion of albumen in the urine, and paralysis in various forms is a frequent sequel.

The treatment of diphtheria in its severer forms consists in the exhibition of alcoholic and other stimulants, and fluid nourishment, at frequent intervals. The removal of the membrane formed in the throat is effected by the application of caustic solutions, dilute acids, or the inhalation of stimulating vapours. In the mild cases, which are unfortunately of less frequent occurrence, little treatment is required beyond the regulation of the bowels and attention to diet.

Diphthong (Gr. *διφθόγγος*). In Grammar, this name is given to what are called *double vowels*, or the union of two vowels pronounced together, so as only to make one syllable.

Diphyans, Diphyes (Gr. *διφύης*, *double*). A family of *Acalephans*, comprehending those singular species in which two distinct individuals are always conjoined, one being lodged in the concavity of another.

Diphyodonts (Gr. *δῖς*; *φύω*, *I generate*; and *ὀδούς*, *teeth*). Those mammalia in which two sets of teeth are generated in the alveoli of the jaw. Zoologists have been led, chiefly by the state of the dentition in most of the early forms of both carnivorous and herbivorous mammalia, which flourished during the eocene tertiary periods, to regard three incisors, one canine, and seven succeeding teeth, on each side of both jaws, as the type formula of Diphyodont dentition. Three of the seven teeth may be *pre-molars*, and four may be true *molars*, or there may be four premolars and three true molars. This difference Professor Owen has shown to be a character of a secondary group or order in the mammalian class. The essential nature of the distinction is as follows: true molars are a backward continuation of the first series of teeth: they are developed in the same primary groove of the foetal gum; they are permanent, because they are not pushed out by successional teeth, the premolars, called *dents de remplacement* by Cuvier. Seven teeth developed in the primary groove is, therefore, the typical number of first teeth, beyond the canines. If, as in *Didelphys*, the anterior three develop tooth-germs which come to perfection in a *secondary groove*, there are then three deciduous teeth; three premolars, and four true molars. If, as in *Gymnura*, the anterior four of the primary teeth develop tooth-germs, which grow in a secondary groove, there are then four deciduous teeth, four premolars, and three true molars. The first true molar of the marsupial is thus seen to be the homologue of the last milk-molar of the placental. When the milk-teeth are shed, and the permanent ones are all in place, their kinds are indicated, in the genus *Sus*, by the following formula:—

$$i. \frac{3-3}{3-3}, c. \frac{1-1}{1-1}, p. \frac{4-4}{4-4}, m. \frac{3-3}{3-3} = 44.$$

Each tooth is distinguished by its appropriate

DIPLEIDOSCOPE

symbol, e.g. *p. 1* to *p. 4*, *m. 1* to *m. 3*, and this number of teeth is never surpassed in the placental Diphyodont series. When the premolars and the molars are below this typical number, the absent teeth are missing from the forepart of the premolar series, and from the back part of the molar series. The most constant teeth are the fourth premolar and the first true molar; and these being known by their order and mode of development, the homologies of the remaining molars and premolars are determined by counting the molars from before backwards, e.g. *one, two, three*, and the premolars from behind forwards, *four, three, two, one*. The incisors are counted from the median line, commonly the foremost part of both upper and lower jaws, outwards and backwards. The first incisor of the right side is the homotype, transversely, of the contiguous incisor of the left side in the same jaw, and vertically, of its opposing tooth in the opposite jaw; and so with regard to the canines, premolars, and molars; just as the right arm is the homotype of the left arm in its own segment, and also of the right leg of a succeeding segment. It suffices, therefore, to reckon and name the teeth of one side of either jaw in a species with the typical number and kinds of teeth, e.g. the first, second, and third incisors—the first, second, third, and fourth premolars—the first, second, and third molars; and of one side of both jaws in any case.

Dipleidoscope (a word made up from Gr. *διπλός*, *double*; *εἶδος*, and *σκοπέω*, *I view*). An optical instrument for indicating the passage of the sun, or a star, over the meridian, by the coincidence of two images formed by a single and double reflexion.

The instrument is constructed as follows: A

B, A C, and B C are three reflecting planes, one of which, A B, is transparent, and the other two of silvered glass, the three forming an equiangular prism. Suppose the side A C to be placed exactly in the plane of the meridian, and a pencil of light proceeding from the sun, S, to fall upon the transparent plane A B at *a*, in the direction S *a* parallel to A C. A portion of this light will be reflected from *a* in the direction *a c*, which is such that the angle *e a B* is equal to S *a* A. Another portion of it will pass through the transparent plane A B, and, proceeding in the same direction, will fall on the silvered mirror at *b*, where it will suffer a total reflection in the direction *b c*, and, falling on the second silvered mirror at *c*, will be again reflected in the direction *c d*, and will pass through the transparent plane A B, and continue its course in the same direction *c d* E. Now, the angles of incidence and reflection being equal, when S *a* is parallel to A C, then *b c* is parallel to A B, and *c d* to C B,

DIPLOMA
